How much was that?—There was three-fifths of a grain.

Have you analysed all the other bottles of liniment?—I have.
Have you compared them with each other?—I have.
They all contain opium.
Have you compared the other bottles of medicine?—I have not examined them so fully.
The one you did examine you tell us did contain morphine?—Yes.
With regard to the liniment, can you tell us its toxic qualities?—I am not a medical man, but I should say there was enough to kill a man in certain circumstances.

The Judge: That is, three-fifths of a grain would kill a man in certain circumstances?—Three-fifths of a grain of morphine is equal to six grains of opium, and I think that is more than sufficient to kill a man. Or said by Mr. Richards: Would you mind looking at the prescription, and telling me as to the bottle of June 12, in which you say there is three-fifths of a grain, what does the prescription say?—The prescription says half an ounce of liniment of opium.
How many grains of opium would that be?—It would be 8 grains of opium.

Are you acquainted with tincture of lobelia?—Yes.
Did you test for that at all?—I did not.
Would that have escaped your notice in the analysis?—Probably.
May I ask what is lobelia?—It is a poisonous herb.
What results have lobelia similar to opium?—That is a question more for a medical man than for me.
Lobelia you say is a poisonous herb?—It is a poison, and I believe is generally a sedative.
I put it to you that had you tested for that all this which you have described as morphine might have been lobelia?—No.
Will you swear that?—Yes.
Why?—Because the characteristics of morphine are very distinct.
You say there must have been either morphine per se or opium per se, is that it?—In this liniment there is a preparation of opium. I say that because I find meconic acid; that is an acid that is only found in opium and poppies. I believe it has been held that the presence of meconic acid proves the presence of opium.
I take it that to the bottle marked June 1 you will not pledge your opinion as to the amount, but you said to the best of your belief you found opium in the bottle?—I know I found opium.

The Judge: That which was supplied on the 12th was the second analysis, he said, and then he found it necessary to ascertain the quantity.
Mr. Richards: You did not get the bottle till July?—I got none of the bottles till July 9.
And you tested them all one after the other?—I tested the first bottle in July.

The Judge: He has examined all the liniments.
Mr. Richards: Tell his Honour what amount of tincture of opium is in the prescription for the medicine?—Twenty minims.
You will not swear upon your oath that they do contain opium?—I will not swear as to the other four.
Would it be possible to have opium in an old bottle, which, when refilled, would still leave its trace?—It would leave a trace, but then I have found very much more than a trace.
You do not think that in any way you could mistake lobelia for opium?—No.
Give me your reasons?—Because the tests for morphine are very characteristic; also the process of isolation would exclude other ingredients.
Have you used what are called qualitative tests?—I used several qualitative tests.
The purchase of June 12 is the only one you have used the double test for?—That is the only one I have examined quantitatively.
As to June 16, 22, and 29, do you say they all contain opium?—Yes.
In what quantity?—In sufficient proportion to say that I believe they are prepared in accordance with what is stated on the prescription.
Have these bottles been in your possession since July 9?—Yes.
I suppose you were only acting on instructions in refusing to allow our analyst to see them until yesterday?—They were not asked for until yesterday.
Did not the solicitor come to you, and seek to obtain one of the bottles for the purpose of analysis?—No.
Re-examined by Mr. Grey: You have some of the morphine, the result of the analysis, with you?—Yes.
Could you have obtained that if there had been lobelia only?—It would be impossible.
The Judge: I assume Mr. Richards admits that the defendant is not qualified?
Mr. Richards: Certainly, because on the last occasion he paid the 2l. 10s.

The Judge: I should like to see Mr. Partridge.

Mr. John Partridge examined by the Judge: Where did you get that prescription?—From Mr. Fitch, of Hackney. He is the district secretary for the Pharmaceutical Society.

What is the history of this prescription? I see it has been made up by different chemists?—I had it stamped by the other chemists whose name you see on it.

They went through the ceremony of stamping this?—Yes.

Mr. Hill of Hackney, pretended that he had made it up?—Yes.

Then Mr. Chipp, he did the same thing?—Yes.

Are they members of the Pharmaceutical Society?—I believe so.

Did they do it to please you?—It was sent out by Mr. Fitch to those other chemists to get it stamped.

Did you do that before you took it to Mr. Mundy?—I handed it to my wife.

Was it stamped by these chemists in Hackney before you handed it to your wife?—The same day.

Mr. Grey: That is my case.

Mr. William Frederick Mundy, examined by Mr. Roberts: You have been in the employment of the Empire Drug Company for some time?—Yes.

You were there at the periods detailed by the witness in the box?—Yes.

On a previous occasion I believe the Pharmaceutical Society took action against you?—They did.

On that occasion you paid the money and did not defend, because you knew you had broken the law?—Yes.

I need hardly ask you, you were more careful after that?—Very much so.

Do you remember this lady coming into your shop and bringing the prescription?—Yes.

What passed?—There is a desk in the shop, and I was standing at the desk copying the prescription.

Mrs. Partridge was at the counter. I said to her, "We cannot supply opium, as opium is ordered in the prescription, but I can put something into the mixture that will answer the same purpose." She said, "That will be enough.

That you swear?—Yes.

Why could you not supply opium?—Because it is in the schedule to the Act, and would be contrary to the law. Then I also mentioned that there was opium in the liniment. I said, "I will omit that, because I cannot supply it." She said, "I will leave it to you to make up.

Did you enter the prescription in the book?—Yes.

In the margin it says: "Tincture lobelia"—"omitted by consent"; and as regards the liniment it says: "omitted by consent." And after "opium" is "Lin. Sapo."

Standing for liniment saponis.

Did you do that on those occasions put in any tincture of opium?—No.

That you swear?—Yes.

What did you put in besides lobelia?—In the case of the liniment I put soap liniment.

The Judge: Then in no case is there any opium?—No.

Mr. Richards: It is a matter of perjury on one side or the other. I produce the book, and challenge a perusal.

The Judge: What is "e. v."?—That means without the bottle.

Mr. Richards: On one occasion she says she paid 10cl., and on another 11cl.; how was that?—I was under the impression that the first time she brought her own bottle, and then I charged her 10cl.; on subsequent occasions I supplied the bottle, and then I charged her 11cl.

When she came the second time did you make any observation for her beyond the ordinary "good morning"?—Yes, I did. I said: "Shall I make it up as before without the opium?" and she said "yes."

You were perfectly well aware, Mr. Mundy, that the Pharmaceutical Society was looking about in Hackney?—Certainly, and I was refusing poison every day, and have good reason to believe that many of the people who came in to ask for it came from the chemist's next door but one, for I watched them.

Did you ever see Mr. Partridge?—I do not recollect seeing him.

Of course you remember Mrs. Partridge?—Very well—distinctly.

You say that you were fully aware of the Pharmaceutical Society being in the neighbourhood?—Yes.

And you fully understood your position, and you pledge your oath that on neither occasion did you put any opium into either of the mixtures?—Yes, I do.

Cross-examined by Mr. Grey: You are the managing director of the Company?—Yes.

What is it?—It is a limited company registered under the Companies Act.

Who registered it?—I registered it.

Were any shares subscribed for?—Oh, yes.

How many?—I really cannot say without seeing the books.

Were there eighty-four shares subscribed for, of which you hold fifty?—I did hold fifty.

You are the only person who looks after the business?—I was at one time.

Mr. Richards: We have not denied that he was there when you bought this.

The Judge: You have parted with some of your shares?—Yes.

When?—Some time ago. I was seeking to leave the business altogether. It would be about August, I should say.

Mr. Grey: Who are the other shareholders?—There are three others. Two are commercial travellers.

Was it registered to carry on the business of chemists and druggists?—I believe it is.

Had you any knowledge of the premises?—Yes.

What is his name?—The present one.

No, at the time these purchases were made?—No, I had not then.

Did you make up any prescriptions that were brought in?—Mr. Richards: Now, sir, is the witness bound to incriminate himself?

Mr. Grey: It is not to incriminate him at all.

Mr. Richards: If you say that I withdraw my objection.

The Judge: I do not see the use of asking it. You rely upon this case of Wheeler.

Mr. Grey: Yes. You say in this prescription that was brought to you there was liniment of opium?—Yes.

You heard the evidence of Mrs. Partridge and of the analyst?—Yes.

Do you swear that that conversation passed with Mrs. Partridge with regard to lobelia—that you could not supply any opium, and that you would put in lobelia instead?—No, I did not say that. I said I could not supply any opium, but that I would put in something else.

What did you put in?—Tincture of lobelia.

You heard Mr. Estes say that there was opium in that liniment?—Yes.

As is seen on this prescription?—I heard him say there was opium, not as seen on the prescription.

The Judge: He said he thought the liniment had been made up in pursuance of the prescription.
Mr. Grey: Do I understand you to represent that you did not put any opium into the liniment? — None what? 

What is that dark fluid in the liniment? — That is burnt sugar.

Then in the liniment what did you put instead of the liniment of opium? — Soap liniment. 

Soap liniment is included in the liniment of opium? — Yes, I believe it is; that is how it is made.

Therefore there was opium in the liniment? — Certainly not.

The Judge: There is no opium in soap liniment, but you cannot make opium liniment without soap liniment.

Mr. Grey: Liniment of opium comprises soap liniment and tincture of opium.

The Judge: You have only to put in a similar quantity of soap liniment instead of opium liniment? — That is what I did.

Mr. Grey: Do you say the analyst could have found any opium in that bottle if you had put none in? — He might have found it if somebody else put it in.

Do you say anybody interfered with that bottle? — I have no evidence of that.

Do you say that Mrs. Partridge or anybody else never put the liniment in? — The Judge: He says he does not know; he has no evidence of it.

When you got this prescription you said, "I cannot put in the tincture of opium?" — Yes.

Did you discuss with her lobelia? — No; I simply said I could not supply the opium, but I would put in something which would answer the same purpose.

You did not tell her what? — No.

What is the effect of lobelia? — It acts as a mild sedative as far as I have had experience.

Did you put more in? — No, the same quantity.

She said she would leave it to you? — Yes.

This was before you began copying the prescription into the book? — Before I had anything to do with that I explained it to her.

When did you copy it into the book, before or after you compounded it? — Before.

You say you put something in the place of the tincture of opium, and something in the place of the opium liniment? — Yes.

Why did you enter in the book the words "tincture of opium"? — It is the custom to copy a prescription the same as it is written.

Did you write these marginal notes at the same time? — Yes, at the same time.

Look at the "omitted by consent"; how is it the "lin. sap." is crowded up? — I do not mean that I put that in at the time of copying, but after the prescription was copied then I put in the price and these other marks.

The Judge: What you said before was not quite accurate? — I did not quite gather what you intended.

Re-examined by Mr. Richards: The words written in substitution were written while she was in the shop? — Yes.

Written before you delivered to her the prescription? — Yes, when the prescription is copied the price is usually filled in, which I did.

Mr. Richards: This, your Honour, is a matter of the greatest concern to my client, and I need hardly say, as his counsel, that I fully saw the position, when I read my brief, that I must take in this matter if my client's instructions were true and accurate, and he was prepared to substantiate them on oath — that someone had been behaving dishonourably in the matter. The best proof that this man knows the law is that, when on a previous occasion he was summoned, he employed neither solicitor nor counsel, but very wisely paid the money into court. Of course he then learnt the lesson that the Pharmaceutical Society with whom he keeps a drug store that supplies goods at a cheaper rate than other chemists. I dare say you are aware that Spier and Pond have put at the bottom of their bottles, "Dispensed by So-and-so, who is a licensed chemist." Now, my client had not at the time and said nothing on the subject. He tells you that day by day he was refusing to sell poisons because he knew of the action of the Society, and he believed the people who asked for them were sent by a chemist a few yards off. Now take the history of the Partridges. Mrs. Partridge gets the prescription from Mr. Moon, and it is clear that Mr. Partridge is also in Hackney.

Mr. Grey: She never said she got the prescription from Mr. Moon. She had instructions from Mr. Moon, but nothing to do with the prescription at all.

Mr. Richards: These people were on the war-path. They were acting the despicable part of agents trying to induce people to break the law. Now they get these bottles in their possession on dates varying from June 1 to June 29. No doubt you are perfectly well aware of the procedure under the Adulteration of Foods Acts, and the same with regard to spirits, and that sort of thing.

The Judge: No, I am not.

Mr. Richards: I have appeared for defendants who are accused of adulteration, and there the things are sealed up in their presence, and a portion is taken away for analysis, and a portion is left with them, so careful is the law where criminal proceedings are taken. I am not saying that the Act here requires that to be done, but here you have a conflict of testimony between two persons, one — I speak with every sympathy for the lady in the box — acting under the direction of her husband, and going into this shop and into that shop — I say they have got to get a conviction. They know that unless there can be a proof on their evidence that poisons specified in the schedule have been sold their mode of livelihood is gone. I put it to you, is it fair that with these bottles she says sealed up — there is one her presence against any evidence and with these bottles sealed up they should be thirty-nine days before they are submitted to analysis? What is more easy than to get up a prosecution of this character when we find that respectable professional men, as I thought chemists were — but I am afraid I must withdraw that remark now — have the audacity, for the purpose of entrapping persons into fines and penalties, to put their mark on a prescription when they have not made it up? I only trust that your remarks will be noted — and I have no doubt they will, as I see members of the press here, no doubt representatives of trade journals — that members of a profession should condone such a thing as would be absolute fraud upon the part of a solicitor or a barrister, if they were to let an opinion go out which was not their's with their signature upon it. You are sitting here as a judge and jury. You are in the position of five or twelve men who are called upon to convict for a criminal offence. You call my attention to the fact that you have not practised in the criminal courts, but I suppose you are perfectly well aware that over and over again a judge in a criminal court will tell the jury that unless the prosecution have made out the case to their satisfaction, and if there is any reasonable doubt in their mind, then the prisoner is entitled to it. I say my client stands in that position. He stands very much in the same position as a man brought before a magistrate for an offence under the Adulteration Acts, which is
a criminal proceeding; this is to all intents and purposes a criminal proceeding, although the law permits it to be brought in the county court. I say the persons who bring these proceedings have to establish their case the same as any prosecutor—without any reasonable doubt. It is the balance of two peoples' word; it is the balance of the woman's word against the defendant's. Against the defendant you know the position he is in—who knows if you find against him that in addition to the penalty you will be convicting him of an offence. I put it to you, as this is in the nature of a criminal proceeding, you cannot take one person's word against another's, without any confirmatory evidence. The shot bottles were kept for these thirty-nine days apart from each other, and from his own hand, they were ever so sufficient to give those results which Mr. Eastes described. I am not attacking the analyst for a moment. I believe he is a gentleman of well-known professional ability, and upon him I doubt, and upon that I put it to you that this case has not been substantiated by the one witness, tainted as she might be in the method in which she is sent to work by her husband, and with the knowledge that this man has already been convicted and paid his fine—that it was not like him to do this. I put it to you that that actually marked his book with a statement which, if you believe that woman's evidence, was utterly untrue. What more likely than that she did forget that she said he was put in what he liked. When she came on the other occasions she said it had done very well.

Mr. Grey: That was never in evidence.

Mr. Richards: I put it to you, sir, that you must in this case be more than ordinarily circumspect in receiving the evidence.

Mr. Grey: I should like to say just a few words after the extraordinary remarks that have been made by my learned friend, the reason for which, no doubt, is to be found in the fact, to use his own words, that there are members of the press present. I submit that purely prejudicial remarks have nothing whatever to do with this case. What has to be proved before you—to-day is, whether poison was sold on these occasions by the two Partridges, and, secondly, whether you Mrs. Partridge, who made those purchases on each occasion. She gave the prescription to the defendant, who, according to his account, did not give her what she asked for—that is to say, he supplied a substance which was not according to the prescription, because in his account, according to his own account, there was absolutely nothing put in the place of the liniment of opium but burnt sugar. I am sorry if that is the way he dispenses the prescriptions brought to him. The analyst was called before you, and he proves, as I submit without doubt, that in each of those bottles of liniment he found a preparation of opium, and in a very dangerous quantity. If you believe Mr. Eastes, that evidence, I submit, decides this case. True, my friend wishes you to believe that Mrs. Partridge on every occasion put into each bottle of the liniment and each bottle of the medicine a certain amount of opium, for she must have done it for Mr. Eastes to have discovered opium in it. It must be that, or it comes to nothing. Not only that, but the quantity put must have been equivalent to the quantity in the prescription, as Mr. Eastes finds it. That is to say, into each bottle was carefully measured out half a fluid ounce of liniment of opium, and the balance put in the medicine. I ask you to say that could not be so. With regard to the penalties, the Society is bound to see that the Act is rigidly enforced. It is the body deputed by the Legislature to stop unqualified persons selling poisons. What is the defendant in this case? The defendant is the managing director, according to his own account, of the Empire Drug Stores. He possessed fifty shares out of the eighty-four subscribed.

The Judge: He has not got them now.

Mr. Grey: He omits to employ any qualified man to sell the poisons. He himself is in the shop and makes up the prescriptions in a way which, according to what he has told us to-day, must be a very careless manner. As late as December last he was sued by the Pharmaceutical Society for two penalties. He paid up, as his learned counsel says, and one would have thought that would have been sufficient to produce his reformation. That is the reason why the five penalties are sued for to-day—because he does not care about two penalties; they are not sufficient. We are suing to-day for five penalties in the hope that it will prevent him going further, and teach him a lesson in future.

Judgment.

The Judge: In this case the plaintiff Society sues for penalties under the Act, against Mr. Mundy, for having compounded liniment with opium in it. Now this is either one of the most wicked conspiracies on the part of the two Partridges to do an man an injury in order to earn their commission, or it is a true case. I have heard the evidence, and I have seen the prescription book, and unless I can arrive at the conclusion that Mrs. Partridge, or someone on her behalf, has tampered with the medicine she has got from Mr. Mundy, I must arrive at the conclusion that Mr. Mundy is liable to the penalties. Her evidence is unshaken. Of course there is obloquy attaching to her of being an informer, but that has nothing to do with the evidence I have to deal with. She tells her story as to how she bought the medicines, and she is unshaken in cross-examination. The only defence to that is an inculpation—a suggestion entirely without evidence to support it—that, having made up in a way that Mr. Mundy said it was made up, these two people, either Partridge and his wife, or one or the other of them, has taken it and mixed it in the opium prescribed by the Act that there is no slightest evidence in support of that. She seems a decent woman, and gave her evidence in a most straightforward way. I suppose it is not easy to buy laudanum and deal with it in the manner so that you could put it in a prescription. I am not certain as to that, so the evidence stands for the plaintiff. There is laudanum in it. Then we come to the defence. There is the statement of the defendant that he said "I cannot use opium, therefore I will put you in something else—lobelia," and then when we come to the liniment, as to which the evidence of the presence of poison is stronger, that he said "I will put in soap liniment, and that will do as well." There is a mysterious entry in the book which looks to me like an after thought, but I do not decide the case upon it. There is this remark to be made: If, as a matter of fact, Mr. Mundy had said to this woman, "I can use soap liniment, but I cannot use opium liniment," what reason in the world was there for putting in the burnt sugar, unless, perhaps, it was that this prescription had been made up before, and therefore the persons who wanted it for the little child for whom it was to be used would have said—it is not brown, as it should have been. On the whole of the evidence I cannot but arrive at the conclusion that Mr. Mundy has committed a breach of the Act, and must pay the penalties. There will be judgment for the full amount. I have no option.

Mr. Grey: I ask for costs on the higher scale.

The Judge: Very well.
POISONING CASES AND INQUESTS.

A CHILD POISONED BY LAUDANUM.

On October 5, at the Grove Inn, Daybrooke, the District Coroner (Mr. D. Whittingham) committed an inquest in the coroner's room, in pursuance of a summons, the deceased being the death of Harriett Bell, aged ten months, daughter of William H. Bell, collier, of Daybrooke. The child was found dead in bed on Thursday morning. It was in good health when it was put to bed the previous night. The coroner said it had been suggested to him that the child had been in the habit of taking chloroform to relieve pain. Dr. John Logan of Charing Cross Hospital, said he attended the deceased on his admission to the hospital, and it appeared to be suffering from the effects of a poison. Witness was handed a bottle which had contained chloroform. The post-mortem showed that death was due to poisoning from chloroform, and witness arrived at the conclusion that the deceased had drunk from one to two halfounces of chloroform. One ounce was a fatal dose. Mr. J. Reynolds, assistant to a chemist, said on Tuesday evening the deceased came to the shop with a property labelled bottle, and asked for one ounce of chloroform, stating that he wanted it for moths and butterflies. The deceased was sold one ounce of chloroform. The jury returned an open verdict.—Standard.

POISONING BY CHLOROFORM.

Mr. G. H. Hillman, Coroner for East Sussex, held an inquest on October 7, at the Cuckfield Union Workhouse, on the body of a man unknown, found on the previous Tuesday. In a dying condition upon Haywards Heath.

Peter P. Parsons said he found the man lying on his right side. Witness tried to rouse him, but he seemed to want to go to sleep. Witness found the empty chloroform bottles and glass produced lying about two feet from deceased.

Dr. C. Neste, of Haywards Heath, said he was called to see deceased. He was in a complete stupor, totally insensitive. Witness noticed distinctly the odour of chloroform, and attributed the condition of the man to narcotic poisoning.

Dr. A. E. Wells, of Cuckfield, said the post-mortem examination showed the stomach much congested and inflamed, indicating irritable poisoning in addition to narcotic. He attributed death to poisoning by chloroform. He was of opinion that a large quantity of chloroform had been taken, probably over two ounces.

The jury returned a verdict "That deceased committed suicide, but there was no evidence to show the state of his mind."—Sussex Daily News.

CASE OF MORPHINE POISONING.

An inquest was held on October 11, at 14, Emsworth Gardens, South Kensington, the residence of the late Captain Augustus William Travers, formerly of the 5th Dragoon Guards, as to the death of the captain from an overdose of morphine. Mr. Arthur Hope Travers, son of the deceased gentleman, said his father had been in the habit for the last six years of taking drugs to induce sleep; and Mr. Taylor, a chemist's assistant in Cromwell Place, said he had occasionally sold the captain morphine, and also bromide of potassium, which he took in large doses as a sedative. Mr. Pedlar, of Trevor Terrace, said the deceased had a weak heart, and a small dose of morphine might prove fatal under those circumstances. Other evidence was given that Captain Travers was negotiating for the tenancy of another house, and that there was no apparent motive for the suicide. The jury gave a verdict of "Accidental death."—Morning.

POISONING BY POTASSIUM CYANIDE.

On October 11, an inquest was held concerning the death of the infant son of a Willesden photographer named Maxwell. Maxwell told the jury that he had been out of regular employment for fourteen months, and was doing a little at home. He was developing
Two negatives, and while his back was turned the child drank some cyanide of potassium which was standing on a tray, and died in less than a quarter of an hour. Witness was very particular with chronic sales, and always kept them in a locked cupboard. The child had followed his mother to the front door, and Mrs. Maxwell said she was speaking there, and did not notice the boy's return to the room. Coroner Bogg: It seems a little absent-minded to be talking to people with children around and deadly poison about. A verdict of "accidental death" was returned.—Morning Leader.

SUICIDE BY CARBOLIC ACID.

At an inquest held at Wrexham last week on the death of a young man of John Jones, who was proved to have taken a quantity of carbolic acid, the jury found that the deceased died of carbolic acid, taken while he was of unsound mind, adding as a rider they were of opinion that some restriction ought to be put on the sale of such virulent poison, and expressing their sympathy with the young man in their trouble.—Wrexham Advertiser.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT.

SALE OF LAUDANUM DEFICIENT IN SPIRIT.

Before the Bradford Borough Bench, on October 1, Arthur John Powell, chemist, of Stanningley, was summoned for selling laudanum not of the statutory quality. Mr. Quinlan, the inspector, deposed to purchasing an ounce of laudanum from defendant's wife, and subsequently four ounces, which defendant wanted to take out of another bottle, but witnesses insisted upon its coming from the same one. The laudanum was found to be 36 degrees under proof strength. Mr. C. L. Atkinson, in defence, said that the sample should be sent to Somerset House, and a long hearing ensued. In the end the Bench expressed themselves as quite satisfied the laudanum was not what was asked for, and they fined the defendant 5s. and costs.—Bradford Argus.

TINCTURE OF SENNA, AND SULPHUR SOAP.

On October 14, John Charles Meacher, chemist, of Seven Sisters Road and Stroud Green Road, was summoned by Mr. A. L. Bridge, an inspector of the Middlesex County Council, under the Adulteration of Food and Drugs Act, for selling a drug, to wit, tincture of senna, containing only one-half of the extractive matter of the tincture of senna of the British Pharmacopoeia, and also deficient in spirit to the extent of 20 per cent. Defendant was also summoned for selling sulphur soap which contained no sulphur. The cases were taken separately. Mr. A. N. Forbes appeared in support of the summorises for the Middlesex County Council. On the former case the defendant was represented by Mr. Lewis Thomas, barrister; on the sulphur soap case the defendant was defended by Mr. Ruegg, barrister. Mr. Bridge proved the purchase of the tincture of senna at the Seven Sisters Road shop on September 15. Mr. Edward Bevan, public analyst for Middlesex, said in cross-examination that there was no standard for tincture of senna mentioned in the British Pharmacopoeia (sic). Mr. Lewis Thomas, in defence, said that there had been an evaporation of the spirit contained in the tincture. Mr. Bevan said he had allowed for this. Mr. Lewis Thomas said that the drug was supplied by Messrs. Langton, the wholesale druggists, of Finchley, and said as purchased. The defendant said that tincture of senna was not asked for once in six months. Mr. Herbert Collins, described as a pharmaceutical chemist, said that not only was there no standard for tincture of senna, but Professor Attfield said other eminent chemists had said that the weaker the spirit the more effective the drug. Mr. Lane said that that was not the case. He fined the defendant 10s., with £1 10s. costs. In the soap case Mr. Forbes said that the prosecution held that sulphur soap was a drug. Mr. Ruegg laughed. Mr. Lane: Why should not sulphur soap be a drug if it is used for skin disease? Mr. Bridge said that he made the purchase on September 18, and the assistant said, "If there is no sulphur in it, Fraser's will have to answer for it." Cross-examined: He was not put up to get the soap by a rival manufacturer. He expected to find sulphur in the soap, as he would expect to find honey in honey soap. Mr. Ruegg said that with each tablet of soap Fraser's issued a notice which said that the soap was not sold as a curative soap, but it was recommended to persons who suffered from skin diseases. Mr. Lane saw the sample, and said that it looked like an ordinary toilet soap. Mr. Bridge said the sample was not accompanied by the paper Mr. Ruegg had produced, but it did contain a paper recommending the medicinal qualities of sulphur tablets. Mr. Lane said that to make a drug it would be necessary for the prosecution to prove that sulphur soap was generally used for curative purposes. Mr. Bevan, the analyst, said it was extremely probable that all the sulphur had worked into another portion of the soap while in process of manufacture. Fraser's as a third defendant. Mr. Lane said that the prosecution had failed to prove that sulphur soap was a drug any more than tar soap was a drug. He therefore dismissed the summons. Mr. Ruegg said he was instructed to state that his clients had an answer to the case on its merits.—Morning Advertiser.

Correspondence.

SALE OF PROPRIETARY MEDICINES.

Sir,—Attention has again been drawn in the Journal to the sale of nostrums containing poisons, the article bold being Powell's balsam of aniseed. I am not for a moment going to defend Mr. Briggs, but my desire is to draw attention to the statement made by him in defence of having knowingly sold a medicine containing poison. It is reported here that he said, "If you look at the label you will see that it merely states 'Powell's Balsam of aniseed.'" Here is a preparation which time after time has been the subject of litigation, and is well known to contain morphine in most varied quantities, and yet the proprietor continues to sell it forthwith without producing or giving any assurances as to its purity, or anything of a poisonous nature, whilst a retailer selling a bottle of it without affixing his own name and address is liable to a penalty. But the difficulty does not cease with this one nostrum, scores of others—opium, ephedra, lousenges, and pills are in the market, and doublets in our shops at the present moment, under precisely the same circumstances, only waiting the act of some cute friend to bring them into court to our doubtful satisfaction. I am well aware that our esteemed President tells us that "it is the duty of the chemist and druggist to know what he is selling, and that he has no right to sell anything he does not know anything of, and if he does not know, he must either analyse it himself and find out, or object to sell a thing at all which he does not know." Such advice is doublets good in theory, but practically impossible. The question therefore is, what is the remedy? Beyond a doubt the right course is to render the law, whereby the responsibility of making known the fact of any nostrum or patent medicine containing a scheduled poison should rest upon the proprietor, and not till then, shall it be possible for the retailer selling per the requirements of the Poison Act. I should be sorry to impute unworthy motives to our legal friends, but it is within the range of possibilities that the bare suggestion of such an alteration of the Act vividly brings to their minds the old story of the inexperienced young solicitor who, having succeeded to his father's practice, was some years after asked by his father "How do you get on with Mrs.
So and so's case?" "Oh, I settled that long since," he
inconsequently replied. "What? settled it? Why, my son, I
lived upon that case for years." Whether such is the
feeling I wont say, but certain it is that as matters are at
present the lawyers are making a good living out of the
Act. An alternative remedy, I venture to think might be adopted by taking a lesson from certain pro-
prietors of popular remedies, who require chemists to sign an
undertaking not to sell their nostrums below a given price.
Could not chemists in self-defence require proprietors of
the multitude of nostrums with which the trade is bored to
give the wholesale dealers a guarantee that their prepara-
tions do not contain scheduled poisons, and that those
which do contain such poisons shall have the fact, with
the name of the poison, distinctly printed on the outside
wrapper or label? The wholesale dealers on their part affixing
a star or other distinguishing mark against such prepa-
rations in their catalogues? We should then be in a
position effectually to protect ourselves by refusing to
stock any preparation not thus guaranteed. I venture to
throw out this suggestion with the hope that the subject
may be discussed by others in your columns, and some
practical conclusion arrived at.

Chitnary.

Notice has been received of the death of the following:—

On October 15, Joshua Collitt Smith, Chemist and
Druggist, Horbury. (Aged 64.)

On October 15, Francis Thirkettle Silvers, Chemist
and Druggist, late of Camberrall Green. (Aged 61.)
Mr. Silvers was Divisional Secretary for the Parlia-
montary Division of Dulwich (Camberrall), and had
carried on business in Camberrall for over thirty-
seven years, retiring therefrom only about six weeks ago.

Diary of the Week.

Saturday, October 20.

Systems of Tissue.

Leaves.

The general morphology of the tissues of the leaf is essentially the same as that of the stem from which it proceeds. In the case of the typical monostelic stem of Phanerogams (ante, p. 232), each leaf receives a portion of the stele or central cylinder of the stem. Such portion is termed a "meristele," and may be either entire or split up into a number of "schizostele." In schizostele the tendency is for the single primitive stele to break up into as many distinct strands as it possesses vascular bundles. Each strand may consist of but little more than a vascular bundle with a pericycle which may consist of parenchyma alone or associated with spongy or supporting tissue (collenchyma or sclerenchyma). The pericycle, generally homogeneous in the root, is usually heterogeneous in the stem and leaf-stalk. This may be due to partial differentiation into collenchyma or fibres which are generally sclerotic, or to the presence of secretory ducts. The chief part of the conjunctive tissue (ante, p. 232) of the primitive monostele is necessarily excluded from the schizostele and becomes part of the extra-stellar ground-tissue, each schizostele being invested by a segment of the endodermis or bundle-sheath.

The bundles, which run along the junction of the two forms of tissue generally found in the leaf, diminish in bulk as their ultimate ramifications are traced, the number of the constituent elements being reduced and those that remain becoming smaller. In the Pteridophyta the bundles have only free ends; in the parallel-veined leaves of Monocotyledons the finer branches anastomose with each other to form a close system; and generally among Dicotyledons the finer branches also anastomose, but from the meshes of the network formed the ultimate branches project among the mesophyll-cells as free ends. The free ends of the bundles consist of one or two rows of short raphides with close spiral markings, and xylem tubes can be traced quite to the extremity.

Fig. 27.—Hyoscyamus leaf. Upper epidermis, with cells of palisade tissue, p, showing through; h, hairs; st, stomata. x150. (Vogl.)

Fig. 28.—Hyoscyamus leaf. Upper epidermis, with, fu, vascular bundles; k, crystal cells; and p, palisade-cells showing through. x150. (Vogl.)

their place being taken by parenchymatous cells. Bundles also often terminate in connection with glandular tissue (c.f. Vine’s ‘Text-Book of Botany,’ pp. 139 and 184).

The internal ground-tissue of the leaf-blade is termed “mesophyll,” and consists of thin-walled cells varying in form. In thin leaves the whole mesophyll consists of assimilatory tissue, the cells containing chloroplasts or chlorophyll-bodies, which are capable of producing starch-grains and of constructing organic substance from carbon dioxide and water under the influence of light. Towards the surface of the leaf more directly exposed to light the mesophyll occurs as somewhat elongated cylindrical cells, which form a compact palisade tissue, one or more rows in thickness. The cells below, which are less regular and have large intercellular spaces between them filled with air, constitute the spongy parenchyma, single cells of which frequently contain crystals of oxalate of lime. The transition from the one form of tissue to the other may be gradual. The epidermis varies in consistence according to the number of layers of cells it contains. That of the lower surface of the leaf contains numerous stomata, which afford entrance to air-chambers that communicate with the intercellular spaces. A few stomata occur sometimes on the upper surface, and oil-glands may also impinge upon the epidermis of the upper or under side of the leaf, which is frequently more or less covered with hairs. Fleshy and succulent leaves have assimilatory tissue, consisting either of palisade tissue or rounded cells, near the surface only, and the internal mesophyll is destitute of chloroplasts. Certain leaves, too, which are equally exposed to light on all sides have stomata in equal numbers on both surfaces, and the palisade parenchyma is also developed in relation to both the dorsal and venal surfaces, whilst the spongy tissue is either absent or limited to a few layers in the middle of the leaf-blade, and the intercellular spaces between the palisade-cells are relatively larger. In leaves floating on water, again, the greater number or the whole of the stomata exist on the upper surface.

Examination of Leaves.

The structure of leaves should be studied in the whole organ, in transverse sections, and by the aid of the isolated elements. (1) After ascertaining as much
as possible from the external appearance of the leaf when magnified, the whole or a portion of it should be soaked in chloral hydrate solution, which will render it transparent and enable its internal structure to be studied as a whole. (2) Sections should then be prepared from fresh leaves, or dried ones softened by soaking in water. These should be cut transversely, both in the direction of the midrib and at right angles to it. For this purpose the material is placed between two pieces of elder pith or fresh carrot, and sections of the whole are cut and transferred to a dish of water. The leaf sections are then easily separated for examination. (3) By macerating the leaves in solution of caustic potash varying in strength from one to five per cent. the epidermis on both sides may be detached, and the elements of the mesophyll and vascular bundles may also be isolated for separate examination. Each of these steps is essential to a thorough investigation of a leaf, particularly if it is desired to attain facility in the recognition of powdered specimens. For the reactions of the various elements reference may be made to the previous articles in the Journal, or to Poulsen's 'Botanical Micro-Chemistry.'

**Hyoscyamus Leaf.**

The leaves of hyoscyamus are soft and viscid, and the epidermis (Fig. 27) on both sides is covered with hairs, which are long, soft, and jointed. On drying, the midrib becomes very conspicuous, and the rest of the leaf shrinks considerably and acquires a greyish-green hue. A transverse section (Fig. 29), though a fresh leaf or dried material softened in water, shows that the long palisade-cells occur under the ventral or upper surface only, the spongy parenchyma beneath being somewhat closely packed, and including cells that contain single crystals of calcium oxalate that are comparatively small in size. The hairs when magnified are seen to be either unicellular or multicellular, the terminal cells of certain of the latter being in some cases expanded in a head-like form, constituting glands which exude a viscid substance that causes the fresh plant to feel clammy to the touch. Various forms of the multicellular hairs of hyoscyamus are illustrated in Moesler's 'Pharmakognosischer Atlas.' The epidermis consists of a single layer of cells, and stomata occur in the epidermal tissue of both upper and lower surfaces of the leaf. The spiral vessels of the vascular bundles are very prominent (Fig. 28).

**Stramonium Leaf.**

The fresh leaves of stramonium are somewhat firm and juicy, downy when young, but smooth nearly so at maturity. After drying they become brittle, and the upper surface is usually green or brownish-green in colour. The hairs vary in shape in a similar manner to those of hyoscyamus, but simple and glandular hairs occurring on the leaves, but they are much shorter than in hyoscyamus. Stomata occur on both surfaces of the leaf, and the epidermis consists of one layer of cells only. The arrangement of the mesophyll is similar to that of hyoscyamus, but the intercellular spaces in the spongy parenchyma are much greater in stramonium (Fig. 30). The crystals are here clustered instead of single, and much larger in proportion than those of hyoscyamus. In the vascular bundles the spiral vessels are the most prominent constituents.

**Senna Leaf.**

Senna leaves of commerce are strictly the leaves of pari-pinnate leaves. They are rather soft and brittle, conspicuously veined, and covered with a very short and fine pubescence which is dense on the midrib. Examination of a transverse section (Fig. 31) shows that it differs markedly from the examples already described. The epidermis apparently consists in part of two layers of cells, but this is due to the deposition of mucilaginous certain cells. The hairs are all unicellular and simple. The manner in which they are inserted between the epidermal cells is characteristic of senna. But the most important difference is the existence of palisade-cells on both sides of the lamina. The spongy parenchyma, which is the confined to the middle of the leaf includes cells containing both single and cluster crystals of calcium oxalate. A number of these crystal-cells are investing one of the vascular bundles as in a sheath (fc, Fig. 31), and where bundles are cut longitudinally, the spiral vessels are shown.
MODERN DEVELOPMENTS OF HARVEY'S WORK.*

BY DR. T. LAUDER BRUNTON, F.R.S.

CHEMISTRY OF THE CIRCULATION.

There is a consequence of the circulation to which Harvey has called attention, although only very briefly, which has now become of the utmost importance, and this is the admixture of blood from various parts of the body. After describing the intestinal veins, Harvey says:—

"The blood returning by these veins, and bringing the cruder juices along with it—on the one hand from the stomach, where they are thin, watery, and not yet perfectly chylified; on the other, thick and more earthy, as derived from the feces—but all pouring into this splenic branch are duly tempered by the admixture of contraries."†

Harvey's chemical expressions are crude, for chemistry as a science only began to exist about a century and a half after Harvey's death, yet the general idea which he expresses in the words which I have just quoted is wonderfully near the truth.

The most important constituents of the blood are chloride of sodium and water. Chloride of sodium is a neutral salt, but during digestion both it and water are decomposed in the gastric glands and hydrochloric acid is poured into the stomach, while a corresponding amount of soda is returned into the blood, and its alkalinity increases pari passu with the acidity of the stomach. Part of this alkali is excreted in the urine, so that the urine during digestion is often neutral or alkaline, and possibly some of it passes out through the liver with the bile of the pancreas and intestinal juice, where, again mixing with the chyle from the stomach, neutralisation takes place, so that neutral and comparatively inactive chloride of sodium is again formed from the union of active alkali and acid. But it is most probable that what occurs in the stomach occurs also in the other glands, and that it is not merely excess of alkali resulting from gastric digestion which is poured out by the liver, pancreas, and intestine, but that these glands also decompose salts, pour the alkali out through the ducts, and return the acid into the blood.

We are now leaving the region of definite fact and passing into that of fancy, but the fancies are not entirely baseless, and may show in what direction we may search out and study the secrets of Nature by way of experiment; for what is apparently certain in regard to the decomposition of chloride of sodium in the stomach, and probably in the case of neutral salts in the pancreas and intestine, is also probable in that important, though as yet very imperfectly known, class of bodies which are known as symbionts. Just as we have in the stomach an inactive salt, so we have also an inactive pepticin which, like the salt, is split up in the gastric glands and active pepine is poured into the stomach. But is the pepine the only active substance produced? Has no other body, resulting from decomposition of the pepticin, been

---

Jaborandi Leaf.

Commercial jaborandi also consists of leaflets, being obtained from imparipinnate leaves. They are of a leathery consistency, have a prominent midrib below, and in transmitted light numerous oil glands are visible. The epidermis (Fig. 32) is one-layered, with a thick cuticle, and palisade tissue is seen to be almost absent, only a very thin layer being visible on the upper side of the lamina. The bulk of the meso-

Fig. 32.—Jaborandi leaf, T.S.; ep, epidermis; pal, palisade-tissue; scl f, sclerenchymatous fibres of peri-
cycle. x45. (Greenish).

phyll consists, therefore, of spongy parenchyma, which includes large oil glands and cells containing cluster crystals. The oil glands are similar in structure to those occurring generally in the leaves of Rutaceae and Myrtaceae, and are largely distributed on both sides of the leaflets. They also occur in the petiole. There is considerable development of xylem and phloem in the vascular bundles, in the middle of which a certain amount of conjunctive tissue appears, and the sereicytic layer of the midrib consists of scleren-

hymatous fibres.
poured into the blood while the pepsin passed into the stomach? Has the inactive peptinogen not been split up into two bodies active when apart, inactive when combined? May it not be fitly compared, as I have said elsewhere, to a cup or glass, harmless while whole, but yielding sharp and even dangerous splinters when broken, although these may again be united into a harmless whole?

This question at present we cannot answer, but in the pancreas there is an indication that something of the kind takes place, for Lépine has discovered that while this gland pours into the intestine a ferment which converts starch into sugar, it pours through the lymphatics into the blood another ferment which destroys sugar. Whether a similar occurrence takes place in regard to its other ferments in the pancreas or in the glands of the intestine we do not know, nor do we yet know whether the same process goes on in the skin, and whether the secretion of sweat, which is usually looked upon as its sole function, bears really the relationship to cutaneous activity which the secretion of bile bears to the functions of the liver. There are indications that such is the case, for when the skin is varnished not only does the temperature of the animal rapidly sink, but congestion occurs in internal organs, and dropsey takes place in serous cavities, while in extensive burns of the skin rapid disintegration of the blood corpuscles occurs.

It is obvious that if this idea be at all correct a complete revolution will be required in the views we have been accustomed to entertain regarding the action of many medicines. In the case of purgatives and diaphoretics, for example, we have looked mainly at the secretions poured out after their administration, whereas it may be that the main part of the benefit that they produce is not by the substances liberated through the secretions they cause, but returned from the intestines and skin into the circulating blood.

MEDICATION BY ORGANIC JUICES.

How important an effect the excessive admixture of the juices from one part of the animal body with the circulating blood might have was shown in the most striking way by Wooldridge. He found that the juice of the thyroid gland, injected into the blood, would cause it to coagulate almost instantaneously, and kill the animal as quickly as a rifle bullet. What is powerful for harm is, likewise, powerful for good in these cases, and the administration of thyroid juice in cases of myxœdema is one of the most remarkable therapeutic discoveries of modern times. Since the introduction by Cavistic’s of peptin as a remedy in dyspepsia, digestive ferments have been largely employed to assist the stomach and intestine in the performance of their functions, but very little has been done until lately in the way of modifying tissue changes in the body by the introduction of ferments derived from solid organs. For ages back savages have eaten the raw hearts and other organs of the animals which they have killed, or the enemies they have conquered, under the belief that they would thereby obtain increased vigour or courage; but the first definite attempt to cure a disease by supplying a ferment from a known glandular organ of the body was, I believe, made in Harvey’s own hospital by the use of raw meat in diabetes. It was not, however, until Brown-Séquard recommended the use of testicular extract that the attention of the profession became attracted to the use of extracts of solid organs. Since then extract of thyroid, extract of kidney, extract of suprarenal capsule have been employed, but even yet they are only upon their trial, and the limits of their utility have not yet been definitely ascertained.
The individual character is given to wool grease by an interesting substance called cholesterin, the chemical formula of which is \( \text{C}_{27} \text{H}_{48} \text{O} \). This substance is soluble in hot alcohol but precipitated in cold, in the form of tabular crystals somewhat resembling silver nitrate. As the extracted wool grease does not precipitate in the crystalline form, I think it is fair to infer that the cholesterin exists in the wool fat chemically combined with the fatty acid, and not in a state of mixture. Cholesterin is not saponifiable, but it makes a most perfect emulsion, taking up 120 per cent. of water, and remaining in that emulsive state for years; a sample in my possession is three years old, and still shows no signs of separating.

Degras finds its chief use in the finishing of leather, superseding tallow for that purpose to a great extent, on account of the low price of the former, and because of its penetrating and emollent nature. Degras is used to some extent in the manufacture of wool-oils, rope-oils, etc. Many persons have been led to believe that this waste material, which has polluted our streams and formed a subject for much discussion, is used extensively in the manufacture of soap. Some months since an article appeared in one of our local newspapers, from which I quote the following words: “In regard to finding a market for this material, I think it possible to sell it to almost any soap manufacturer. A large business is done in New York in this, and at a price of 2 to 24 cents per pound.” To say the least, this newspaper statement is misleading. Degras has been used to a slight extent by a few soap manufacturers, but the results have been anything but satisfactory. Cholesterin is unsaponifiable, and a positive injury to the soap. It has no detergent properties, and is undesirable as a “filler.” There is no doubt that new outlets for this interesting product will be discovered eventually.

CONTRIBUTIONS TO THE CHEMISTRY OF CERIUM.*

BY L. M. DENNIS AND W. H. MAGEE.

The mineral cerite was first found in one of the iron mines of Bastnäs, in Westmanland, Sweden. Its peculiarity was noticed as early as 1751 by Croated,† and in 1794 it was analysed by d’Elhuyar,‡ in Bergmann’s laboratory, and was considered by these two chemists to be a silicate of lime and iron. In 1803 the mineral was again examined by Berzelius and Hisinger, and by Klaproth, and nearly at the same time, but independently, they discovered in the mineral a new oxide. Berzelius and Hisinger named the earth ceria,§ after the planet Ceres, which had been discovered two years before by Piazzi. Klaproth called it ochristerde,¶ from its brownish-yellow colour. Fortunately the former name was adopted, for the latter name would have been a misnomer, since pure cerium dioxide, as we now know it, has a pale-yellow colour.

From that time to the present, cerium and its com-

* Read at the Brooklyn Meeting of the American Chemical Society, August 15, 1894, and reprinted from the Journal of the American Chemical Society.
§ Abländ. s. Physik, Kemi och Mineral, 1, 43.
¶ A. Gehl., 2, 508; Beiträge, 4, 140.
pounds have frequently been the subject of investigation, but the work of the earlier chemists is not of direct importance, since the ceria upon which they worked was, as we now know, a mixture of various oxides, chief among them being those of cerium, lanthanum, and didymium.

In 1839, however, Mosander made known a discovery of the highest importance; namely, that ceria was not a simple oxide, but a mixture of at least two. The newly isolated earth he called lanthana, and this, in 1842, he split up into lanthana proper, and another oxide which he named didymia. *

Dating from the time of Mosander's discoveries, the results of the various investigations upon cerium acquire, of course, much greater value, but the chemistry of this element and the other rare earths has remained one of the most difficult problems in the field of inorganic chemistry, chiefly because of the great similarity in the chemical behaviour of these different elements and the consequent difficulty of separating any one of them completely from the others. Naturally, then, in an experimental investigation of the compounds of cerium, the first problem to be solved is the preparation of pure ceria.

I. SEPARATION OF CERIA FROM THE OTHER EARTHS.

The ceria was extracted from allanite from Amelia County, Virginia, a large amount of this mineral having been most kindly sent to us by Professor W. G. Brown, of the Washington and Lee University. Nineteen hundred and twenty-four grammes of the finely powdered allanite was heated in large porcelain evaporators with concentrated hydrochloric acid until the supernatant liquid became dark brown. The syrupy liquid was allowed to cool and was then poured off, the residual mineral being again treated in the same manner until it became grayish-white, three treatments of about ten hours each usually sufficient. A portion of the residue was then moistened with concentrated sulphuric acid and heated until all of the acid was driven off. The white residue was then, in small portions at a time, into ice-water, and to the filtered solution, oxalic acid was added. No precipitate resulted, showing that the treatment with hydrochloric acid had removed all of the rare earths.

The rare earth chlorides, mixed with those of iron, aluminium, calcium, etc., were then distilled and filtered. A portion of this filtrate was treated with hydrogen sulphide for twenty-four hours, the solution being kept at 70°, but no precipitate appeared. The hydrogen sulphide was then expelled by boiling, the sulphur was filtered off, and the filtrate was added to the original solution. This was oxidised by nitric acid and a concentrated solution of oxalic acid was then added in excess. The pinkish-white precipitate of the rare earth oxalates was allowed to settle, and the oxalates were then washed by decantation with hot water until the supernatant liquid was colourless. They were then digested in large evaporators with one per cent. hydrochloric acid until all iron had been removed and were then dried and ignited in a muffle furnace. The reddish-brown oxides resulting weighed 410 grammes, a yield of over twenty-one per cent.

The oxides were dissolved in concentrated nitric acid. To facilitate solution sulphurous acid was added to one portion and oxalic acid to another, but with no perceptible benefit in either case. There were obtained four litres of an almost syrupy solution which showed the didymium absorption bands very strongly.

Many different methods for separating the ceria from the accompanying earths have been proposed, but none of them seem to yield cerium which is completely free from lanthanum and didymium unless the method proposed be many times repeated. Mosander, * the earliest worker upon this problem, obtained a mixture of didymia and lanthana free from ceria by precipitating the mixed chlorides with potassium or sodium hydroxide and passing chlorine through the suspended hydroxides. Cerosous hydroxide is oxidised to the insoluble ceric hydroxide while the hydroxides of lanthanum and didymium are changed to chlorides and dissolve. Join* found that the treatment must be made seven times before the ceria is completely free from didymia and lanthana. Poppe added sodium acetate to the solution of the chlorides and ran in chlorine, the ceria being precipitated. Later, instead of passing in chlorine gas he added sodium hypochlorite and boiled. Gibbes* boiled the mixed earths with nitric acid (1:2), having first added considerable lead dioxide. Zechieschel* heated the rare earth sulphates with red lead and nitric acid. In each of the last two methods ceric oxide is formed. Winkler* separated ceria and didymia from lanthana by adding mercuric oxide to the solution of the chlorides and then potassium permanganate until the solution is coloured by the latter. Ceria and didymia are precipitated. Welsbach** precipitates the ceria by fractional crystallisation as cerium ammonium nitrate. Bunsen first*** proposed to ignite the oxides with magnesia, to dissolve out the ceria as cerium magnesium nitrate and then pour the solution of the latter into a large amount of very dilute nitric acid, whereby ceric oxide is precipitated. Later*** abandoned this method and proposed instead the method which has been most employed for preparing pure ceria. A solution of impure cerium sulphate is poured into boiling water containing one part of nitric acid to the thousand, and basic cerium sulphate is thrown down. This procedure must be repeated several times and is also very wasteful because the yield is small, so that it can be used with advantage only on material that is already nearly pure. Brauner*** increased the yield by dissolving firstly in nitric acid instead of in sulphuric acid, driving of

the excess of acid and precipitating with boiling water containing nitric acid. Debray* fused the nitrates of the earths with from eight to ten times their weight of potassium nitrate at a temperature between 300° and 350°. The nitrate of cerium is decomposed, leaving the oxide which is insoluble in water. The other nitrates are undecomposed and are soluble in water. Many repetitions were necessary to free the ceria from the other earths. Pettinson and Clark† heated the mixed chromates to 110° when cerium chromate decomposes to ceric oxide, the other chromates remaining unchanged.

For the separation of the ceria from the other earths in the allanite solution obtained as stated above, the authors first employed the Moosander-Jolin method, which so eminent an investigator as Cleve has pronounced to be the best. The nitrate solution of the earths was diluted, potassium hydroxide was added in excess, and well-washed chlorino gas was run into the solution for from four to five days. The white precipitate of the hydroxides soon changed to a dirty violet and became light yellow soon after the action of the chlorine began. The ceric oxide was washed by decantation until the wash-water gave no precipitate with ammonium hydroxide, this washing occupying nearly a week, as the precipitate settles very slowly. The precipitate was then dissolved in hydrochloric acid and the treatment with chlorine was repeated. After seven complete treatnents the concentrated solution of cerium chloride showed no absorption bands when a layer ten Cm. thick was examined with a Kriis spectroscope. The solution was then nearly neutralised with ammonium hydroxide and hydrogen sulphide was run in for twenty-four hours, the solution being warmed to 70°. A very slight precipitate of copper sulphide resulted. This was filtered off, the hydrogen sulphide was expelled by boiling and the separated sulphur was removed by filtration. To the filtrate was added a concentrated solution of pure oxalic acid, a snow-white precipitate of the oxalates of the rare earths resulting. This precipitate was treated with a hot solution of hydrochloric acid (two per cent.) until the washing liquid failed to give a reaction for iron when tested with potassium sulphocyanate and ether. The oxalate was then dried and ignited in porcelain crucibles over the blast-lamp. The resulting oxide was of a pale yellow colour resembling in tint very light chamois leather.

In the meantime the method of separation proposed by Debray was tried upon another portion of the rare earths. It was found that the melting point of the mixture of rare earth nitrates and potassium nitrate was usually about 325°. (The melting point of potassium nitrate is stated to be 339°.) Upon treating the fused mass with water it was found that the insoluble residue contained, even after two fusions, appreciable amounts of didymium. Since cerium nitrate begins to decompose at 290° and didymium nitrate at about 300°, the cause of the presence of didymium in the insoluble cerium oxide is evidently to be ascribed to the high melting point of the nitrate mixture employed by Debray. If, then, the melting point of the mixture could be lowered the probable result would be that less of the didymium nitrate would be decomposed, and it seemed reasonable to expect that, by sufficiently depressing the melting point, cerium oxide completely free from didymium might be obtained by a single fusion. With this end in view the potassium nitrate was replaced by sodium nitrate, the melting point of the latter, 316°, being somewhat lower than that of the potassium nitrate. But even with this salt more than two fusions were necessary to free the cerium from didymium.

Carnolley and Thomeson* have shown that while potassium nitrate melts at 339° and sodium nitrate at 316°, a mixture of these two salts in molecular proportion melts at 231°. Consequently, this mixture was next tried with the rare earth nitrates, the details of the method being as follows:—

The oxalates of the rare earths, after being freed from iron, as above described, are placed in porcelain evaporating dishes, the oxalates being covered by funnels of such size that when inverted they fit inside the edge of the evaporating dish. Concentrated nitric acid is now poured over the oxalates. Action begins at once in the cold, but it can be greatly hastened by warming on a water-bath. After the nitrogen oxides cease to come off, and the liquid has become clear, the solution, which should be so concentrated as to be syrupy in consistency, is poured while still hot into large porcelain crucibles half-filled with the well-ground mixture of potassium and sodium nitrates. About enough of the solution to completely cover the dry nitrates is poured in and the whole is thoroughly mixed by stirring.

For heating the crucibles a double air-bath was used. Both of the air-baths and the two covers were lined within and without with asbestos board. Through the two covers, openings were made through which thermometers could be introduced at various points within the inner bath. The crucibles were placed in circular openings cut in a piece of asbestos board, this board resting on pipe clay rods in the inner air-baths. The asbestos board was also pierced with many smaller openings to allow free circulation of air. The air-bath was heated by two Bunsen burners, the height of the flame being kept constant by means of "precision" gas-cocks.

After the crucibles have been placed in position the temperature is brought up slowly, too rapid heating being liable to cause the mass in the crucibles to swell and run over the edge. The two covers are placed in position, and a thermometer is inserted through the centre opening to such a distance that its bulb is on a level with the bottoms of the crucibles. The heat is gradually increased until the thermometer shows a temperature of 300° in the inner bath. The mixture melts at a little below 230°, and decomposition of the cerium nitrate begins almost immediately. As the temperature rises the brown fumes come off copiously, the

* Compt. rend., 96, 828.
† Chem. News, 16, 239.
evolution gradually lessening as the heating continues. If, after removing the covers, it is seen that the evolution of gas from the fusion has entirely ceased, then the decomposition possible at the temperature employed is complete. This usually takes from four to five hours after the temperature has risen to 300°. It was found that the cerium nitrate is not entirely decomposed even when the temperature has been kept at 350° for some time, and also that if the temperature rises above 320° the cerium oxide will contain some didymium. After the evolution of nitrogen oxides ceases, the bath is allowed to cool rapidly, since by so doing the solid mass can usually be removed by inverting the crucible and tapping the edge gently. If it cannot be removed in this way it can usually be loosened by throwing a jet of hot water around the upper edge. The removal of the mass in a solid block is of advantage, since the condition of the decomposition may be judged by the colour of the oxide which has collected at the bottom. If it is bright yellow or nearly white the ceria is probably pure, but if brownish in colour then some of the didymium nitrate also has been decomposed.

The solid mass is now treated with hot water, which dissolves all but the oxides. These are allowed to settle and the supernatant liquid is decanted off through a filter. More hot water containing from four to five per cent. of nitric acid is poured over the oxides, and the liquid is brought to boiling and poured while hot through the filter. This is repeated six times and finally the oxides are washed with hot water alone, the washing being continued until the wash-water gives no precipitate with ammonia.

The oxides are dissolved by heating them with concentrated sulphuric acid until fumes of sulphur trioxide begin to escape, allowing the mass to cool and then treating it with a large amount of water. More rapid solution can, however, be effected by throwing a jet of water upon the hot sulphates and stirring the mass constantly. There is some tendency to spatter, but solution is obtained in much less time and with much less water than in the first procedure. A concentrated solution of cerium sulphate thus obtained showed no didymium absorption bands in a layer thirty Cm. thick.

To test the separation quantitatively, weighed amounts of pure cerium and didymium oxalates were mixed, the mixture was dissolved in nitric acid as above described and the mass was fused with the mixed alkali nitrates. The soluble portion from the first fusion was evaporated down and again fused with the alkaline nitrates, and this solution and fusion was repeated in all four times. The temperature during each fusion was about 300°. The insoluble cerium oxide resulting from the fusions was in each case free from didymium, and of the total cerium taken more than sixty-three per cent. was obtained completely free from didymium by the four fusions.

Another sample of the mixed nitrates was fused at about 330°. The layer of cerium oxide which collected at the bottom of the fused mass showed a brown coloration at the edges, and the insoluble residue, after being carefully washed and dissolved in sulphuric acid gave the didymium bands clearly. The filtrate tested by the hydrogen peroxide method mentioned below showed some cerium still present with the didymium.

From the foregoing it will be seen that while the method is not quantitative it is nevertheless quite rapid and the yield is comparatively high. Its chief merit lies in the fact that the cerium oxide resulting from each single fusion is free from didymium, as advantage which does not seem to be possessed by the other separation methods with which the authors are acquainted.

(To be continued.)

**OPIUM TRADE OF CHEFOO, CHINA.**

The remarks to be made on opium in these reports might almost be stereotyped for annual use. Indian opium remains the luxury of the rich, and the trade in it is so small as scarcely to call for remark. There is a slight increase in the total amount imported in 1893, 339 chests, instead of the 311 chests of 1892, but the value of the Indian opium brought annually to Chefoo has dropped below 150,000 taels, and will probably become smaller still as time goes on.—*Consular Report.*

**TOBACCO CULTIVATION IN CUBA.**

Pinar del Rio, the western province of Cuba, is given up almost entirely to the cultivation of tobacco. The plantations are scattered about in all directions, generally a mile or two apart. They consist of a number of small fields ("vegas") of about ten acres each, selected wherever the land is richest. The rest of the land is entirely uncultivated. The tobacco seed is sown in nurseries, about ten lbs. being used per acre. In October and November the young plants, when about three inches high, are bedded out in the tobacco fields, in furrows two feet apart. During the three months the plants take to reach their full size, the greatest care is taken of them. Each plant is constantly examined, the green tobacco caterpillars killed, and the furrows kept perfectly clean with the plough. When the plants have grown its big leaves, generally about ten in number, all the small leaves are picked off the stalk, and on reaching its full height the head of the plant is also picked off. This allows the leaves to expand and spread out in the sun. The female plant gives the best leaves for capas (the outside wrapper of a cigar), as the leaves are larger and stronger. The colour of the leaf is bright green until ready for picking, when it begins to turn yellow and spotty. They are then gathered by cutting the stalk in such a manner that two leaves remain on each piece of stalk. The leaves are then strung over thin poles in the drying houses, one leaf each side of the pole, and left to dry about five weeks. The drying houses are large, airy barns, thatched with palm leaves, the inside being arranged with rows of poles one above another. On being taken down the leaves are put together in bundles of about 100 leaves, which are made into bales of usually eighty bundles and wrapped up in palm leaves. The bales are then ready for sale, and are taken in this state to the storing rooms of the cigar manufactories in Havana.—*Consular Report.*
The Pharmaceutical Journal.
FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, OCTOBER 27, 1894.

Editorial Department.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to "Street Brothers," 5, Sora Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased. Cheques and money orders must be made payable to "Street Brothers."

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Bromidge,—17, Bloomsbury Square, London, W.C.

STANDARDS OF PURITY.

From time to time we have had occasion to protest against the manner in which the sale of drugs not of the proper standard of quality by unregistered persons was attributed to chemists and druggists. For, as is well known to our readers, in the great majority of cases where such offences are reported in the daily press as committed by "chemists," the defendants have no legal claim to that title. In the annual government report under the Sale of Food and Drugs Acts, too, the statement of the number of convictions for adulteration or substitution of drugs is recorded in such an unsatisfactory way as to give ground for the not unnatural inference that the defective substances were purchased of chemists and druggists alone, rather than, as is actually the case in most instances, of grocers and small shopkeepers. Yet the painful fact remains that in a certain number of instances, limited though that number be, chemists have been found so wanting in care or honesty, as to cast discredit on their class by failing to rebut the evidence of official analysts, when given in courts of law. It is evident that the many not so distinguished may suffer under imputations unfairly cast upon the whole class of chemists and druggists because of the faults of the few. Any alteration in the law, therefore, which may tend to single out offenders more clearly than at present, especially if it be more clearly indicated what does or does not constitute an offence, should be cordially welcomed by our readers generally.

As the result of long-continued agitation on the part of the Society of Public Analysts, a draft bill was prepared by the council of that society in June last, for the purpose of amending the adulteration of food Acts, and to make better provision for the sale of food and drugs in a pure state. In this bill it is proposed that the term "drug" shall include medicines for external or internal use, and it is provided that "no person shall, except for the purpose of compounding as hereinafter described, mix, colour, stain, or powder, or order or permit any other person to mix, colour, stain, or powder any drug with any ingredient or material so as to affect injuriously the quality or potency of such drug, with the intent that the same may be sold in that state, and no person shall sell any such drug so mixed," etc., etc. The penalty in each case shall not exceed fifty pounds for the first offence, but imprisonment for a period not exceeding six months with hard labour shall follow each subsequent conviction. Ignorance of, or inability to detect, sophistication is regarded as a reasonable excuse, but, again, the sale to the prejudice of the purchaser of any drug not of the nature, substance, and quality of the article demanded, shall render the seller liable to a penalty not exceeding twenty pounds. Further, any drug sold under any name included in the British Pharmacopoeia shall be required to comply with the description, character, and tests for such drug as specified in the latest edition, with amendments, of the British Pharmacopoeia, provided that the drug be not included in a scheduled list of articles bearing names identical with B.P. remedies, but not required to be of B.P. quality. Compounded drugs must be composed of ingredients in accordance with the demand of the purchaser, but drugs not recognised in the B.P. may be mixed with anything not injurious to health nor intended to promote fraud, if when sold they are distinctly labelled as mixtures. Accidental deterioration of the article, or accidental abstraction, spontaneous separation, or evaporation of the ingredients, shall be no defence under the last section.

Since nothing can excuse either the wilful sophistication of drugs or want of care in ascertaining their purity before sale, pharmacists are not likely to find anything particularly objectionable in the definitions of offences under the proposed Act, but it is more than probable that they will see grave cause for protesting against certain suggested details of procedure. The most notable propositions are that "no certificate, other than that of the public analyst, shall be received in evidence, unless supported by the oral evidence of the analyst giving the certificate," and that there shall be constituted a board of reference, "consisting of the chief chemical officer of the Inland Revenue Laboratory, a person nominated by the General Medical Council, three persons, being public analysts, nominated by the Local Government Board, and a person nominated by the Board of Agriculture." The effect of these clauses will be to enormously
and unduly magnify the position of the public analyst. It is difficult to see why the certificate of that individual should be considered of equal value as evidence with the oral evidence of other chemists, frequently experts with both greater general and special knowledge than himself. Nor is it easy to comprehend why he should usurp half the representation on the board of reference. The tendency is plainly in the direction we have formerly deprecated in these pages, viz., endeavour on the part of public analysts to constitute themselves advocates and judges, rather than content themselves with the performance of their proper duties five thousand under the adulteration laws. A satisfactory board of reference should include representatives of those individuals whose businesses are chiefly affected by the law, and if two out of the three public analysts were replaced by nominees of representative bodies of chemists and grocers respectively, greater dependence might be placed upon the fairness of its decisions. As the scheme stands, it is calculated to give rise to great dissatisfaction and grave inconvenience, with no corresponding advantage, unless the creation of a large class of irresponsible claimants from material of doubtful fitness be regarded as such. Though, as already suggested, pharmacists generally would doubtless be willing to lend their support to any satisfactory bill for amending the existing law, there is every reason for their seeking to modify or defeat the passing of any bill which would impose further unnecessary restrictions upon their already much hampered business, or deliver them unprotected into the hands of more or less incompetent officials.

BOOKS MISSING FROM THE LIBRARY.

The attention of Members, Associates, and Students of the Society is directed to the announcement on page v. of our advertising columns, where a list is published of books missing from the Society's Library. Our readers are requested to search the shelves and return the volumes they may find at the earliest possible opportunity.

COLONIAL AND FOREIGN ISSUE.

The Journal of December 1 next will have a special colonial and foreign circulation, as more than 1000 copies of that issue will be sent to chemists and druggists and others interested in pharmacy, in Australia, New Zealand, Tasmania, India, Ceylon, Philippine Islands, Hong Kong, Straits Settlements, Malay States, China, Japan, South Africa, West Indies, Canada, etc., etc.

ANTI-DIPHTHERITIC SERUM.

An appeal made by the Paris Figaro for funds to enable the Pasteur Institute to supply Dr. Roux's anti-diphtheritic serum to all medical practitioners who might apply for it, has resulted in the sum of £10,000 being raised. It is stated that the Paris Academy of Medicine has reported in favour of this system of treatment.

POISONS IN PROPRIETARY MEDICINES.

We have received advance proof-sheets of Messrs. F. Newbery and Sons' catalogue for 1895, and note that the proprietors have adopted the suggestion made in our columns last week by Mr. E. B. Vizer, of Brighton, indicating proprietary medicines labelled "Poison" by the manufacturers by placing the letter "(P)" against their names.

BUSINESS CHANGE.

Mr. J. A. E. Breeze, chemist and druggist, Poole, has recently acquired the business of the late H. E. Field, 70, Oxton Road, Birkenhead, which he intends to carry on under the same style as formerly. The business was in the hands of the former proprietor for more than a quarter of a century.

THE HARVEIAN ORATION.

The annual Harveian Oration was delivered on Thursday, October 18, before the President and Fellows of the Royal College of Physicians, by Dr. J. Lauder Brunton, F.R.S., honorary member of the Pharmaceutical Society. It dealt with "Modern Developments of Harvey's Work," and an extract from it, which we reprint at page 335 of this week's Journal, will be found to possess considerable interest from a chemical point of view.

LIVERPOOL CHEMISTS' RETAIL PRICE LIST.

We are asked to state that the Council of the Liverpool Chemists' Association is engaged upon the revision of the above price list, and as the work is extensively used in all parts of the country they invite suggestions from all quarters, with the object of making the work as complete as possible, so that it may be still more generally adopted. Every detail is receiving most careful consideration, and it is expected that the new edition will be ready by the beginning of the new year. Communications may be addressed to the Honorary Secretary of the Liverpool Chemists' Association, Royal Institution, Colquitt Street, Liverpool.

THE ROYAL FREE HOSPITAL.

There was a social function of some interest at the Royal Free Hospital, Gray's Inn Road, on Wednesday afternoon last, when the governors and their friends were invited to meet the Lord Mayor (who is a member of the Committee) and Lady Mayoress, they having expressed a wish to inspect the new buildings which have recently been added to the hospital. His Lordship expressed much pleasure in being present, and strongly advocated the claims of the hospital on the benevolence of the public. As informal procession was then made round the buildings, which are of the most approved construction, and were generally admired. The medical students (who are all of the gentler and fairer sex at this hospital) were most assiduous in looking after the comfort of their visitors and pointing out the most interesting features of the establishment. In addition to the governors and members of committee present there were, among the visitors, medical men and women (including Dr. Garrett-Anderson), and several members and friends of the Pharmaceutical Society. Naturally, the dispensary was visited and keenly inspected by the latter: the fittings, which are very complete and convenient, were, we believe, arranged under the advice of Mr. Martindale, and it was stated that 300 bottles of medicine and upwards are often dispensed daily by the dispenser and his assistants. Altogether a very pleasant time was spent by the visitors in inspecting the building and hearing of the good work done at this institution.
CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held at 103, Great Russell Street, on Thursday, October 18, the President, Mr. R. H. Jones, in the chair. Letters were received from Messrs. Cartleigh, Andrews, and Tyrer, regretting their inability to attend. A very interesting discussion on "The duties of the Pharmaceutical Society as an educational body" was opened by the reading of a paper of which the following is an abstract:

THE DUTIES OF THE PHARMACEUTICAL SOCIETY
AS AN EDUCATIONAL BODY.

BY R. H. GANE.

My object in thus contriving my paper is to bring to your notice three questions: (1) What is the duty of the Society in this respect? (2) How is that duty at present discharged? (3) How may it be better fulfilled?

The first question is one that can be answered briefly. Personally, I am of opinion that in the direction of the Society offering every educational advantage, in order that we may qualify ourselves as professional men, alone lies hope for the future pharmacist. That brings us to the second query as to how the obligations of the Society are at present discharged. They are discharged in the establishment of the School of Pharmacy and in the foundation of the Research Laboratory, but in such a way that the majority of the younger members are prevented from taking advantage of those institutions. The average assistant is not as a rule blessed with too much of this world's good things, and the high fees at the official school render it impossible for the great majority to obtain the education which it alone affords. The Society spends annually on that establishment some £800, and has an average of about eighty students, so that each student obtains a premium of about £10 a year, and it is just those students who could best afford to do without it. Put plainly, it is making the poor pupil to educate the rich. The amount annually contributed to the Society from students for examination fees is about £8000, more than one-third of the total income of the Society, in addition to the students' subscriptions, and we are surely entitled to ask for some consideration in return for those payments, as well as the students in the School of Pharmacy.

For the man who has passed and wishes to continue his studies there are no facilities whatever offered for attending advanced classes or courses of laboratory instruction. True there is the Research Laboratory of the Pharmaceutical Society, but the advantages offered by that Institution are necessarily limited.

Mr. Gane then proceeded to criticise the outlay on the Research Laboratory and the direction of the work performed there, which was referred to as being more chemical than pharmaceutical, and he concluded that the manner in which the educational duties of the Pharmaceutical Society are at present discharged might be improved upon.

He then continued as follows:

And now to consider how those duties may be better performed. In the first place, we must now clearly what we want, and then cast about for the best means of attaining the end in view. It seems to me that two things are wanted: greater educational facilities for students, and secondly, some facilities for those who have qualified and desire to extend their studies beyond the ordinary school courses.

The means by which those ends may be attained are matters not so easily disposed of, but I venture to suggest a few which seem to me to be practicable, and, I think, would effect the desired improvement. With regard to affording greater advantages to students, of late years we have heard a great deal about a curriculum for pharmaceutical students. As to its advisability, I shall say nothing, but that this is given, where is the school in which such curriculum may be carried out? On the Council's own showing there is hardly a pharmaceutical school which is fit to carry out any such project, and it seems to me that before we talk of a curriculum we should take care that there are schools and teachers capable of carrying it out thoroughly. Complaints are rife as to the unsatisfactory state of most schools of pharmacy, but hitherto no attempt has been made to provide better. A scheme such as that suggested by Dr. Symes some years ago would seem to be the easiest way out of the difficulty. Existing schools, where suitable, could be utilised, and any such, when in receipt of a grant from the Pharmaceutical Society ought to be periodically inspected by officials of the Society in order that the work might be well carried out. A grant of £100 each to ten schools situated in the provinces or in London should be amply sufficient to enable those schools to be self-supporting, and to offer good education to students, combined with good teachers drawn from the ranks of pharmacists. That such grants are needed and are useful is shown by a glance at the history of some of the provincial schools.

The Sheffield School of Pharmacy, for instance, one of the most promising, owes its flourishing condition largely to the help of the Council in granting it support. The fact that so many schools are inefficient is not due, said Mr. Schacht some time ago, to lack of funds, but to insufficiency on the part of the teachers. That may be so, but does not the one imply the other? and with larger funds better teachers might be obtained. In spite of Mr. Schacht's dictum that provincial education is hopeless, I still hold that the system advocated years ago by Dr. Symes would prove most beneficial to the cause of education. A few schools officered by capable men selected periodically by the Council or their agents, would do much to diminish the outrageous system of "crams" employed so largely in the metropolitan schools of pharmacy to-day. This seems to me a point well worthy of discussion, and I put it before you for your consideration, and trust that some good may result from it.

That brings me to the second division of this question, namely, the providing of educational facilities for graduated men. At present, we are dependent on our own resources, and on the sufferance of outside colleges for help of this kind, which is too often outside the reach of the average man. What are wanted are, I think, classes for men who have passed their examinations, in medicine, in materia medica, chemistry and botany; such as will be of practical value to the pharmacist in business. Such a course of lectures and demonstrations should include information about the manufacture of commercial substances connected with pharmacy, such as indigo, rubber, dyes, earthenware, and the like, and some chemical courses on commercial organic analysis and the analysis of food products, such as would be found of practical use in the course of business. One important subject would be the use of the microscope in practical histology, with a view to promote its use generally
in the examination and recognition of drugs. In view of the important part which bacteriology seems destined to play in the future of medicine, classes in this science might be added with advantage.

Having thus briefly touched upon what I consider the most important points in the subject before us, I leave it to you to discuss, and trust that your deliberations may result in some practical expression of opinion.

In the absence of Mr. Gane, the paper was read by one of the secretaries.

The President said he was sure all present would appreciate the clever manner in which Mr. Gane had handled this subject. He thought it an admirable one for debate, and also that if everyone would endeavour to understand this question of education good results were bound to accrue in the future, for it was the fundamental principle upon which to base all efforts for the furtherance of all trade organisation schemes. He did not see how the Society could relinquish its educational programme, for the providing of education was one of the objects it had in view at its incorporation, the examining function having been imposed upon it subsequently by Act of Parliament. With regard to the Research Laboratory, he quite agreed with remarks by Mr. Gane as to its having been aimed at too great things, and would have done better service, he thought, if it had undertaken work of a less pretentious character. Evening classes for post-graduate men he very strongly advocated, for personal efforts often than not consisted of desultory reading, and at the best the results acquired were incomparably inferior to those ensuing from attendance at lectures and demonstrations.

Mr. Tickle considered the subject of education was of more vital importance than that of trade unionism even.

Mr. Long regretted the evidence there was, as shown by the increased number of cheap schools, of a desire to avoid expense by students, rather than acquire a sound education. He thought the plea for postgraduate classes had his utmost earnest support, and should they be instituted he hoped non-qualified men would avail themselves of them.

Mr. Hill thought such classes would confer a great benefit on the ordinary retail assistant, especially if they offered facilities for conducting analysis of food stuffs and other articles submitted to them for analysis. He was also in favour of a reduction of the fees in the Society's school, so as to allow access to the advantages it offered by a greater number of students.

Mr. Crouch was of opinion that it was not altogether desirable to lessen the burdens of students to a greater extent. For by making sacrifices the calibre of the student would be lowered, and in circumstances no better off than the average pharmaceutical student who managed to wrestle successfully with the prolonged and most costly curricula of the medical schools.

Mr. Plant considered ample provision existed already for attending night classes, for those held at King's College were fully meetiing the requirements of any who wished to develop their education, and further ones, under such auspices as proposed, would not meet with success. He would welcome very heartily any system by which apprenticeships could be registered and masters thereby be compelled to give those bound to them an efficient training.

Mr. W. Moore favoured the making of grants by the Society to provincial schools, which should be controlled by local associations, such grants being regulated by the number of passes effected, thus embodying the principle which obtained in the South Kensington Science and Art Department.

Mr. Sage stipulated this payment by results principle, in its relation to education, as the worst of incentives, and very much deprecated the suggestion for its adoption. He thought there were objections to the Society's exercising the dual functions of education and examination, though he had always been in favour of its providing evening classes.

Mr. Hart held that the representative Society was the best body to furnish education for its candidates for examination, and cited the instance of universities discharging both functions.

Messrs. Guyer, Read, and Morley also joined in the discussion.

Mr. Long then moved a resolution to the effect:—

"That this meeting of the Chemists' Assistants' Association is of opinion that a course of post-graduate lectures would be appreciated and supported, and requests the Council of the Pharmaceutical Society to consider the advisability of providing such a course during the coming winter."

Mr. Hill seconded the proposition.

Mr. Crouch proposed as an amendment that "laboratory instruction" be included in the course.

This was seconded by Mr. Tapper, who considered that without this any such course would be incomplete.

Mr. Long having agreed to this addition to his proposal, the President moved, and Mr. Sage seconded, the resolution "That this meeting of the Chemists' Assistants' Association is of opinion that a course of post-graduate lectures and laboratory demonstrations would be appreciated and supported, and requests the Council of the Pharmaceutical Society to consider the advisability of providing such a course during the coming winter."

The motion being put to the meeting was carried unanimously.

The Secretary was then instructed to forward a copy of the resolution, in its amended form, to the Secretary of the Pharmaceutical Society, after which the proceedings terminated.

THE WESTERN CHEMISTS' ASSOCIATION (OF LONDON).

The annual meeting of the above Association was held on Wednesday, the 17th inst., the President, Mr. Andrews, in the chair.

The President opened the proceedings with a few remarks, giving a short résumé of the work of the past session, and concluded by thanking the members for the kind consideration and assistance he had received from them during his occupation of the presidential chair. He felt sure that the Association was accomplishing the object for which it was established, namely, the promotion of sound intercourse and unity amongst the members of their calling, and urged upon all members the desirability of trying to induce their friends to join, and thus promote the success of the Western Chemists' Association (of London).

The Hon. Treasurer read the balance sheet for the past year, which was unanimously adopted.

The election of the committee for the ensuing year then took place, and the scrutineers reported that the following gentlemen had been duly elected, viz.:—

Mr. Cracknell proposed, and Mr. Phillips seconded, that the following addition be made to Rule 7, viz.:—

"And any member whose subscription shall remain unpaid after twelve months, and to whom two notices shall have been duly sent, shall cease to be a member of the Association, but shall be eligible for re-election on payment of the deficient and previous year's subscriptions." This was carried unanimously.

Mr. Cracknell then proposed, and Mr. Mathews seconded, that the annual dinner of the Association be held at the Café Royal, Regent Street, on Wednesday, November 21, and that the price of the tickets be six shillings and sixpence. This was also carried nem. con.

A vote of thanks was passed to the auditors and scrutineers.

A vote of thanks was also proposed, and carried with acclamation, to the President for his conduct in the chair during the past year, and the President having replied, the meeting terminated.

Provincial Transactions.

MIDLAND PHARMACEUTICAL ASSOCIATION.

INaugural Meeting.

The inaugural meeting of the session of the Midland Pharmaceutical Association was held on the 18th inst., at the Midland Hotel, Birmingham. Mr. R. Darow Gibbs (president), occupied the chair, and amongst those present were Messrs. W. Jones and F. J. Gibson (vice-presidents), Dr. Paul, Messrs. A. W. Gerrard, F. H. Prosser, F. H. Alock, H. Boucher, H. Culwick, H. S. Shorthouse, H. C. Morris, F. Gibson, C. Page, Alfred Southall, A. W. Southall, J. Poole, E. J. P. Ferraday, F. Darow, W. Burton, W. Scott, C. Thompson, W. McCombe, F. Dale, T. Donald Watson (London), and George E. Perry (hon. sec.).

The President, on behalf of the Association, gave a hearty welcome to Dr. Paul and Mr. A. W. Gerrard, whose presence, he said, was highly appreciated. Nothing was better calculated to keep alive that Association and to infuse enthusiasm amongst them than visits on occasions like that. He then delivered his address, of which the following is an abstract:

INAUGURAL ADDRESS.

BY R. DAROW GIBBS.

To-day we make a start on a new session in connection with this Association, a session which I hope will not be of less importance than those which have passed, and one I also hope you will each and all contribute to make a success.

It is on an occasion like this that it seems desirable to take a glance over the work this Association has done in the past, and what it is now doing, to see how far above the standard originally fixed, and to make a careful estimate of its future possibility of usefulness.

In order to do this it is necessary to set very clearly before ourselves the aims and objects of such an association, and this, to my mind, does not appear to have been done with that distinctness which is necessary. Now the division of the work into proportionate and the clearness with which associated interests and the end in view is defined.

That some value is attached to associations is evidenced by their increasing number in every direction, for every conceivable purpose, by the length of time this and other associations have been in existence, and by the fact that collective opinion and action can hardly be obtained without them.

In turning one's attention to the past, the first thing to notice would be that 1868 saw the passing of the Pharmacy Act, and 1869 the formation of the Birmingham and District Chemists' Association. Thus we have had twenty-six years of the workings and twenty-five years of the influence of this Association. Now twenty-five years is, I venture to think, sufficient time to give a trial to, and prove the necessity and desirability of, a society, and the present seems an opportunity for casting a glance round and endeavouring to see if there are not any serious flaws. We do to ourselves, and I include myself among the number, the results seem poor. When you think of the number of meetings and discussions that twenty-five years have produced, you would at once estimate that the Association is well up-to-date with ideas and principles, and that we became a force by our unity and readiness for action; but as far as my experience goes we are as far from being in accord as ever we were, and quite as far from accomplishing or having anything to accomplish. Still I would not deny that this Association has been of real use. I see work done, quietly it is true, but none the less done. The interconnection of work is often done when we come across, seems to have been sought, at first by the publication of a retail and dispensing list, which seems to have been of equal value to the funds of the Association as to the user, for I find its sale brought £24 to the funds of the Association during the first three years, and how much more I do not know. You will not call that a failure. Then there were many little annoyances, such as licences for storing petroleum, the Storage of Poisons Bill, and many other matters, in a way small yet annoying, which this Association dealt or helped to deal with successfully, but the largest share of work, which I consider of greater value than what is called social, it has brought together men engaged in the same class of work, who at one time looked upon each other with suspicion, but who now feel that friendship and commerce may go hand in hand, with much to gain and nothing to lose, and who can estimate the value of this and other societies in helping rather than hindering each other; yet with all this we never seem to have created any policy, we believe what is right.

If we are slow in attack, we have many times shown ourselves quick to defend, for I find in the past, whenever any interference came, from whatever quarter, pharmacists were quite able to take care of themselves, and it needed but activity on the outside to stir up activity within. Hence I infer that matters cannot be so very ill-arranged, yet I find discontent everywhere. There is a general feeling that for some undefined reason we do not share in the general prosperity; that whilst the wealth and population of this city go up year by year, the number of pharmacists, if they do not grow smaller in number, become poorer in pocket, and this in spite of the marvellous development of the sciences we claim to know—chemistry. Yet the race is being run and won by men having to my mind less opportunities. But you may suggest that a man should seek and find work and success within what is called legitimate pharmacy. I am not clear what legitimate pharmacy is, but I am quite clear that if the whole of our work was somehow to limit ourselves to what is generally understood to be legitimate pharmacy, their wives would not be long in finding it out. I would rather, therefore, suggest that, in the exercise of your work, you are storing up valuable utilities which you should place at the disposal of mankind, bearing in mind that the greater their value the more you will obtain in exchange. I wish to press this point, because I find people are ready to blame everybody
except themselves, or to seek success not by raising the value of their services, but by seeing how far they can own the possession of the commodities, and the scientific knowledge and the eagerness of medicine to take up the newest and most advanced ideas, unless the Society sets about increasing the stringency of the examination and extending the subjects, you may expect to find that medicine will draw her supplies not from the half-educated pharmacist, but from outside socialists.

I now come to that august body, the Pharmaceutical Society. Originally a trade society, a self-imposed educating and examining body, and a benevolent society, the world was able to appraise its work, and I believe pharmacists have done so, wholly to the credit of the 1868 Act, and you had better not think of the consequence if you do not want nightmare. To-day the public are protected by the Pharmacy Act, and by a society comprising about one-fifth of the qualified pharmacists, the remaining four-fifths finding it cheaper to look out. In this right to the Pharmaceutical Society for giving effect to an Act of Parliament passed in the interest of the community, which, if not in the interest of the community, ought not to have been passed at all. What right has any society to claim the position of body of English pharmacy which is supported by a small minority. The Pharmacy Act and the Sale of Food and Drugs Acts spring from a public demand for protection, and if I were addressing the public I should say that the poison schedule might be extended to include all powerful drugs which are prepared for and intended to be used as medicines, without feeling that I was acting in opposition to the public good.

Having then, given up our ideas of seeking State protection, let us turn our attention to matters we can well afford to discuss with great hopes of success, the obtaining the qualification of the pharmacist. The objection of granting exclusive titles to corporations which, acting for the general good, seek to raise the status of their profession. Now physician, surgeon, barrister, and solicitor are clear and distinct titles, but when you come to pharmacy what do you find? First, names that denote trade or growth. The early chemist or druggist grew, as you are aware, out of the antagonisms of the physicians and apothecaries. We rose to our present position not because the country demanded it, but to save ourselves from being crushed by the apothecaries, and it was entirely upon our own account we created it, or it may mean a whole load of local chemist, a cash chemist, having for its object the union of the members of the trade into one body, the protection of their general interests, and the improvement and advancement of scientific knowledge by education, examination, registration, and representation. What calls the respective spirit is to be found everywhere, in our craft as much as elsewhere. It is the first thing a man seeks for who forgets everyone but himself. Who is it that does not want his special calling protected, but always at the expense of someone else. I have little faith in what the State can, or will, or should do. If there are too many restrictions they must not come from us, but be imposed by the State in the interest of the community. The Pharmacy Act and the Sale of Food and Drugs Acts spring from a public demand for protection, and if I were addressing the public I should say that the poison schedule might be extended to include all powerful drugs which are prepared for and intended to be used as medicines, without feeling that I was acting in opposition to the public good.

Who is it that does not want his special calling protected, but always at the expense of someone else. I have little faith in what the State can, or will, or should do. If there are too many restrictions they must not come from us, but be imposed by the State in the interest of the community. The Pharmacy Act and the Sale of Food and Drugs Acts spring from a public demand for protection, and if I were addressing the public I should say that the poison schedule might be extended to include all powerful drugs which are prepared for and intended to be used as medicines, without feeling that I was acting in opposition to the public good.
I have now pointed out the mistake of seeking protection from the State, the desirability of a clearer title, of increasing and extending the examination, of separating the duties of the Pharmaceutical Society from those of the qualified pharmacists, of drawing closer to medicine, and, lastly, making the hours and conditions of labour more attractive.

Before bringing my address to a close, I will make a few suggestions to the younger men who are coming into the profession. There are many utilities of usefulness are as great in pharmacy as they are in any other department of human activity, and that usefulness consists in seeking for and satisfying wants. Every desire is a want, and everything which conduces to the satisfaction of a want is a utility. Wealth is the expression of the mass of utilities. Keep that before you and you will see that your life will consist of exchanging utilities. The greater the number and value of your utilities the greater the number and value you can get in exchange. In pharmacy, as elsewhere, you want energy and perseverance, knowledge and reliability; with these nothing can stop you from realizing life’s best hopes.

Dr. Paul said he anticipated he should have full support in proposing a vote of thanks to the President for his address. Mr. Gibbs had referred to the value of the Association, and he had brought before them a number of subjects that might well be dealt with by that or any other association of pharmacists, and chemists and druggists, to their advantage, and the advantage of their fellows elsewhere. Those topics upon which he had touched would take too long to enter upon them, but there was one he thought specially deserving of notice, and that was upon the value of associations of that kind for the sake of establishing personal acquaintanceship. It was not so much the work of paper-reading and discussions at the periodical conferences and meetings that took place that was valuable, as the opportunity they afforded to establish personal intimacy between persons engaged in the same occupation and having a certain amount of sympathy one with another in their pursuits. That was an influence that could be well and usefully exercised by associations of that kind, and he thought that was one of the most interesting points to which their President had referred.

Mr. Gerrard, in seconding the motion, said that he had great pleasure in coming to Birmingham to listen to his old friend Mr. Gibbs in his position of President of their Association. It was not usual to criticise the President’s address, but he was sure there were many points in the address which might be taken up by them at future meetings of the Association. If they could come to an agreement upon one or other of those points and could get other local associations to agree with them and send deputations or resolutions to Bloomsbury Square and influence the Council, they would be doing a really good work for themselves and for the whole body of chemists and druggists. If the Council of the Pharmaceutical Society did not respond to them in the matter, it was open for them to elect a new council. There was one point upon which he begged to differ. Mr. Gibbs thought that a qualification ought to entitle a man to a vote. He (Mr. Gerrard) asked them as members who subscribed their money and gave their time and attention to that Society, if they would like men who had had no sympathy with them to come in and vote away their funds, whilst paying not one farthing towards their Society. It did not seem a right thing to say because a man got a qualification he should have a vote and be capable of upsetting that which was established on a fairly firm basis. With reference to protection, he agreed that they were badly off so far as protection for their trade was concerned. He thought they should ask for better protection for their title, and druggist’s books. Mr. R. H. Mitchell, president, occupied the chair, and there was a hope for them if they met together and discussed those questions of education, and if they were determined that the education of the pharmacist should be improved, and especially the early education. He felt it was not too much to ask that the preliminary examination of the Pharmaceutical Society should be extended. They would then be able to draw their apprentices from a better class of society, and in ten years they would see a great improvement in their position and bring themselves more into touch with the medical and scientific classes.

Mr. Alfred Southall supported the motion, and said what they had been told was very much to the point. They might at some of their future meetings discuss the questions brought forward. He was not inclined to take quite so gloomy a view of the chemist and druggist’s position as their President, and did not think they need be so much discouraged.

Mr. Gibson (Vice-President) also supported the motion. He said that he believed a great deal of what they now complained of was due to the lack of association among chemists and druggists.

The motion was carried unanimously.

The President said he had spoken with true sincerity, and he hoped in their meetings later on they would have an opportunity of discussing what he had advanced. If they could prove what he had suggested to be wrong he should not be offended. It was necessary for an association to have a policy, and that was the reason he had formulated the opinions he had.

The remainder of the evening was devoted to social intercourse.

LIVERPOOL PHARMACEUTICAL STUDENTS’ SOCIETY.

The inaugural meeting of the present session of the Liverpool Pharmaceutical Students’ Society was held on Wednesday, October 18, when the meeting was held at the Café Royal, Nelson Street, Newcastle-upon-Tyne. There was a company of fully sixty present, and a very enjoyable evening was spent.

MEETING OF PHARMACY STUDENTS AT NEWCASTLE-UPON-TYNIE.

The past and present students of the North of England School of Pharmacy, with a few friends, held a social meeting on Friday, October 1, at the Café Royal, Nelson Street, Newcastle-upon-Tyne. There was a company of fully sixty present, and a very enjoyable evening was spent.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

INAUGURAL MEETING.

The first meeting of the session was held on Thursday, Oct. 18, with a fairly good attendance of members. When Mr. W. M. McVail delivered the opening address, an abstract of which is here given.

INTRODUCTORY SESSIONAL ADDRESS.

By Dr. D. C. McVail.

When your secretary did me the honour to ask me to address you to-night, and did not suggest any subject in particular, you will understand that I have been in considerable difficulty as to what I could talk about. It would be impertinent on my part to give you advice, or even to offer suggestions on matters in which you are more expert than I am. I have, therefore, decided to consider what there may be yet remaining of common ground between the physician and the pharmacist, as it is in this border country that useful conferences may most suitably be held. Year by year this "no man's land" is lessening in area; more and more the internist, as time goes on, is becoming the dividing line between your work and ours. This is inevitable. Advancing science is increasing rapidly the field in both departments; fewer and fewer doctors dispense medicines to their patients, and fewer and fewer pharmacists prescribe as well as dispense. In Scotland this division of labour has always been more marked than in England, and our advancement in this particular is more rapid even now than it is south of the Tweed. You benefit by it, so do we, and the public gains more than either of us. In the near future the Scotch medical man will not be a pharmacist at all, and the educated pharmacist will have too intelligent an appreciation of the manifold work that lies within his own domain to seek to wander into the province of the medical practitioner. The great common end of the prescriber and dispenser is to relieve suffering and prolong life. In the fulfillment of this ideal duty your way is more easy than ours, and you have attained greater perfection than we have. Four fundamental obligations you have to fulfill. Perfection in the preparation of every article as regards the accuracy of its contained ingredients, absolute purity of every preparation, rigid exactitude in dispensing every prescription, and such a knowledge of dosage as will enable you to detect any blunder that the prescriber may inadvertently commit. But beyond the fundamental qualifications you confer many benefits on the physician. You guide him as to what is compatible in the ingredients of his prescriptions. You point out to him the faulty condition of the administrative media, and you assist him in rendering nauseous doses elegant in appearance and pleasant to swallow. But much more still you have accomplished, and are accomplishing, and that not in all respects to your own immediate pecuniary benefit. Take, for example, the introduction of tablets in recent years, an absolutely novel and hygienic mode of administration. These are the most economical preparations you have ever given us, and they deprive you of much of a prescription that otherwise would come to you. Their effect is so immediate and, so far as relief of pain is concerned, so certain, that frequently, on a night visit or other emergency by the little film that forms the surface of the dose, the㗘 decayed physician had the most rudimentary knowledge of the structure of the body. At the conclusion of the address, a unanimous vote of thanks was accorded to Dr. McVail.
Parliamentary and Law Proceedings.

POISONING CASES AND INQUESTS.

DEATH FROM IMPROPER USE OF CARBOLIC ACID.
George Hill, aged 56, of Hill Lane, Southampton, a retired miller, died on Tuesday, October 9, after accidentally burning his feet by soaking them in a strong solution of carbolic acid. Medical evidence attributed death to affection of the kidneys caused by absorption of the acid. Verdict: "Death was due to disease of the kidneys, caused by the improper use of the acid."—Hampshire Advertiser.

CASE OF CHLORODYNE POISONING.
A man, name unknown, about 25 to 30 years old, was found unconscious on Hayward's Heath on Tuesday, October 9, and died shortly after being moved to Cookfield Union Infirmary. Three chlorodyne bottles were found by his side, and medical evidence showed that deceased probably died from narcotic poisoning. Verdict: "Suicide."—East Sussex News.

ACCIDENTAL POISONING BY LAUDANUM.
William Rogers, aged 32, of 50, Blanket Row, Hull, described as a chemist, but not on the register for 1894, died on Friday, October 12, from the effects of laudanum taken in mistake for tincture of rhubarb. Verdict: "Death from mistake."—Eastern Morning News.

POISONING BY OXALIC ACID.
Edward John Hanbury, of Essex Street, Kingeland Road, Islington, a slipper maker, died on Friday, October 12, as the result of drinking whisky in which he had dissolved oxalio acid. Verdict: "Suicide while of unsound mind."—Echo.

POISONED BY A LIMONET.
Lydia Caroline Hales, aged 25, drank four ounces of Limonet on Saturday, October 13, and subsequently died. Verdict: "Suicide during temporary insanity."—Morning Leader.

SUPPOSED POISONING BY ARSENIC.
Dr. Thomas Evans Hughes, aged 38, of Wingfield Crescent, Llanbradach, was found dead in bed on Saturday, October 13, with a small phial supposed to contain arsenic by his side.—Western Mail.

ACCIDENTAL POISONING BY CARBOLIC ACID.

POISONING BY OXALIC ACID.
Mary Ann Kelly, aged 26, of Chatham Street, Widnes, died on Sunday, October 21, from the effects of oxalic acid solution, taken in mistake.—Liverpool Mercury.

SPIRIT OF SALT FOR FRUIT SYRUP.
William Frederick Field, aged 15, of Willesden, died on Sunday, October 14, as the result of drinking spirit of salt in mistake for fruit syrup. Verdict: "Death from misadventure."—Daily Graphic.

POISONING BY SPIRIT OF SALT.
Arthur Patrick Hill, aged 40, of Hall Place, Paddington, a house painter, died on Tuesday, October 16, after drinking a large dose of spirit of salt. Verdict: "Suicide while of unsound mind."—Morning.

ACCIDENTAL POISONING BY CHLORAL.
Dr. W. L. Emmerson, sen., aged 72, of Leicester, formerly analyst for the county of Leicester, died on Wednesday, October 17, as the result of an overdose of chloral. Verdict: "Death from misadventure."—Nottingham Guardian.

DEATH FROM OVERDOSE ON LAUDANUM.
William Clelland, aged 40, of Burntisland, died on Thursday, October 18, from the effects of an overdose of laudanum.—Scottishman.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACTS.

WHITE WAX OR PARAFFIN?
At the Wolverhampton Police Court on Friday, October 19, before Mr. N. G. A. Neville, Charles Frederick Lloyd, trading as a chemist at 70, Darlington Street, was charged at the instance of Mr. G. F. Allwood, inspector of food and drugs for the borough, with selling a certain drug, to wit, white wax, which was mainly paraffin, and not of the substance and quality asked for by the purchaser. Mr. Allwood stated that the charge was taken under section 6 of the 1875 Act. On July 23 an assistant, named John Allen, in the weights and measures office, called at the shop of defendant and asked to be supplied with a quarter of a pound of white wax, for which 3d. was charged. The inspector afterwards went to the shop and divided the article in the usual way, and a sample was submitted for analysis. On September 5 a certificate was received stating that the wax was not according to the British Pharmacopoeia, but was mainly paraffin, of which 90 per cent. was found.

Similar charges were also laid against Henry Hudson, described as a chemist, of 1, North Road, and Phillip George Godsell, chemist and druggist, Chapel Ash. Mr. T. G. Greensill represented Mr. Godsell. On July 23 a 1/4 lb. of wax was purchased from Mr. Hudson, for which 10d. was paid, and on analysis it was found to contain 75 per cent. of paraffin. It was on July 20 that sixpennyworth of wax was purchased from Mr. Godsell, and the analytical return for this was that it contained 95 per cent. of paraffin.

Mr. Greensill remarked that they could not deny the analyst's returns, but they sold the article as received from the wholesale chemists. He understood that it was an American production, made in Boston, and described as mentioned in the British Pharmacopoeia. Mr. Godsell bought his business from a Mr. Coleman, and he sold the stock then purchased. He believed this was the first time wax had ever been taken, and it was a hard case.

Mr. Lloyd said they bought the article in good faith, and sold it in like manner, but Mr. Neville said that if wax was ordered that must be sold, and each of the three defendants was fined 20s. and costs.—Express and Star.

* This name does not appear on the Register of Chemists and Druggists for 1894.
Notes and Queries.

VASELONE.

[778.] “Can you give me any information concerning a substance called ‘vaselon’?”

Vaselone is an artificial product intended as a substitute for paraffinum molle. It is described as a solution in neutral mineral oil of stearone (5 per cent.) and margarone (15 per cent.), prepared by distilling stearin and beef suet respectively with lime. A neutral product so obtained is a white, odourless ketone, unaffected by acids. (See Watt’s Dictionary of Chemistry, IV., p. 513.)

A NEW PILL COATING.

[778.] In the case of pills required to pass through the stomach unaltered, Waldstein prefers a coating made from a mixture of shellac and salol dissolved in alcohol. Methylene blue administered in pills so coated was found in the feces and urine, though it was proved that the pills remained undisolved in the stomach (New York Med. Journ. and B.M.J. Epit.).

PEPSIN WINE.

[780.] This preparation is official in the German Pharmacopoeia, glycerin being employed as a preservative. In the second edition of that work the formula was as follows:—Pepsin, 50 Gm.; glycerin, 50 Gm.; water, 50 Gm.; acid hydrochloric, 5 Gm.; white wine, 1845 Gm. That in the later edition, however, is different, thus—pepsin, 24 parts; glycerin, 20; acid hydrochloric, 3; water, 20; syrup, 92; tinct. aurant., 2; sherry, 889, or enough to make 1000 parts. The first four ingredients are directed to be mixed together and allowed to stand eight days. Filtration is then performed, and the other ingredients are added. Schmaleberg objects to the addition of glycerin as being injurious, and other writers have objected to the use of wine, alleging that the alcohol present might hinder the action of the ferment, though no satisfactory evidence appears to have been produced on either of these points. The addition of syrup is strongly recommended by several of these individuals, but a writer in the Bulletin de Pharmacie de Bruxelles suggests that the proportion of syrup should never exceed 20 per cent., or it may check the digestive action of the pepsin. Vulpian having shown that whereas albumin, 10 Gm., may be digested in one hour by pepsin, 0.10 Gm., in the presence of hydrochloric acid, 10 drops, diluted with water, 100 Gm., the addition of sugar, 10 Gm., prolongs the period of digestion to five hours. The presence of alcohol, 1 Gm., or sweet wine, 4 Gm., prolonged the period to one hour and twenty minutes only.

PALLATABLE EXTRACT OF CASCARA.

[781.] Experiments have been undertaken by Frank Edel with the view of ascertaining the most satisfactory formula for this preparation, the basis of the experiments being the following, which he describes as furnishing, in his experience, “the best bitterless extract” — Cascarra sagrada in coarse powder, 16 oz.; calcined magnesia, 1 lb.; water, 18 oz.; alcohol.*

* Alcohol, U.S.P., contains 91 per cent. by weight of absolute ethyl alcohol.

12 oz.; dilute alcohol,* q.s.; glycerin, 2 oz. The cascara and magnesia are intimately mixed, moistened with the water and macerated for several hours. Then pack in a percolator, macerate for forty-eight hours, add the alcohol, and macerate twelve hours longer. Next, percolate with dilute alcohol till exhausted, reserving the first twelve ounces. Recover alcohol from bulk of percolate and evaporate to soft extract, which dissolve in reserved portion of percolate and add glycerin to make sixteen ounces. Various modifications of this process were tried, in the last described percolation being allowed to proceed to exhaustion and, after the recovery of alcohol, four ounces of glycerin added, the whole being then reduced by evaporation to twelve ounces. To complete the preparation liquorice extract, 4 oz. (vide Note 782); fennel oil, 6 drops; and saocharin, 24 grains, were added. “A satisfactory sweetness was produced, and the cascara was completely masked.” The resulting product is described as “an extract of fine keeping qualities and of elegant appearance,” besides being efficient from the point of view of medicinal activity (American Druggist).

LIQUID EXTRACT OF LIQUORICE.

[782.] Some years ago, G.H.C. Klise recommended a liquid extract of liquorice made from the stick extract by extraction with cold water. Frank Edel has used this preparation for the past five years, and suggests its general adoption. It is made by packing stick extract of liquorice, 16 oz., in small pieces, in a percolator, with alternate layers of rye straw, and allowing to macerate with cold water for twenty-four hours. Then run off liquid and put aside in a cool place. Again fill percolator with water, and macerate for twelve hours. Run off liquid, mix with former percolate, and evaporate on a water-bath to twelve fluid ounces. Finally, add glycerin, 2 oz., and alcohol, 2 oz. (American Druggist).

Reviews and Notices of Books.

Twenty years ago men learned in branches of science other than medicine were wont to complain that our doctors paid too little heed to the causes of disease, while they went on tinkering at its effects. Now, happily, no one can bring this charge against the medical profession. Pasteur, with a mind untrammeled by dogma, passed from chemistry to biology, and in biology found in its highest province—medicine—full scope for his great genius. Nor is there need to recall the work of Koch and Lister, and the now great school of bacteriologists, to realise that we have seen a revolution accomplished in medical thought. Whilst the methods invented by Koch have enabled bacteriology to advance by gigantic strides, the study of the pathogenic sporozoa, necessarily conducted by other methods, has been slowly but surely gaining

* Alcohol dilutum, U.S.P., contains 41 per cent. by weight of absolute ethyl alcohol.
ground since the discovery by Laveran of the sporozoae of malaria about 1880.

The author of the handsome little volume before us takes what has been proved of other diseases to form a basis for suggestions as to the probable nature of some affections of the thyroid gland. The essential identity of sporadic cretinism, myxœdema, and kakezis strumipriva is brought into relief, and the marvellous success of the treatment of these affections by the administration of animals' thyroid glands in some form or other is well described. From the nature of the work undertaken by the author, many pages of the book present a confusing haze to the mental gase of the reader. Some passages might be considered rather too hasty. We may instance the following: "Graves' disease in women is an auto-toxins, most frequently caused by the absorption of purulent products, that process being aided rather than induced by the toxins of terror and shock." The toxins here adduced to have yet to be discovered in a form appreciable to chemists, so that at present they must rank with the hypothetical entity enshrined in the word "melancholia." In spite of a few such lapses into looseness of thought, the author has produced a work which will be welcome to thinkers in the medical profession.

"A great book," to use the words of the old Greek writer, is often a great evil." This is an extract from the preface of the work before us. Dr. Abbott's book is very small. The sorrows of those afflicted with stammering are pictured in a page of blank verse, descriptive of an extreme case, and attributed to M. F. Tupper. We are told that many pretentious quacks profess to cure stammering, but only disappoint their dupes. Dr. Abbotts thinks the proportion of stammerers to the whole population of England has increased of late years. The book contains a certain amount of information, but nothing new. The title of the work seems to imply that all cases of stammering are curable, and there is nothing in the somewhat vague references to the author's cases that tends to remove the impression that this is without exception the author's experience. Other medical men who have written on the subject have not been so fortunate.

Indeed, with the best of advice the majority of stammerers stammer on the same, only the minority are curable, or can be taught to mask their infirmity: such is the experience of many able physicians.

Books, etc., received.

New Books and New Editions.

The following are amongst the most recent scientific publications:

ORGANIC CHEMISTRY. By A. BERNTZEN, translated by George Mcgowan. Second English edition, revised and extended. 7s. 6d. Blackie and Son.

PRACTICAL PHYSIOLOGY OF PLANTS. By Francis DARWIN and E. HAMILTON ACTON. Illustrated. 6s. Cambridge University Press.

ELEMENTS OF METALLURGY. By W. JEROME HARRISON and W. J. HARRISON. 2nd ed. 6s. Blackie and Son.

Correspondence.

SCHOLARSHIP AND PRIZE REGULATIONS.

Sir,—Having noticed an article in the Journal of October 13, by Charles D. Allen, on the scholarships and prizes which are open to the pharmaceutical student, in which he laments the paucity of entrants, may I suggest that the regulations are to blame and not the students. Taking the Harvard prize as an example, the limit of age is fixed at twenty-one years. At that age the majority of students are just beginning to take an interest in whatever science has engaged their special attention. Then a large number of apprentices are engaged in the large towns and cities, and can only get into the country once a week for a few hours. What opportunity have these young fellows to make a collection of plants for competition? Raising the limit of age would give all these a much better chance, and would not have any disadvantage. Might I suggest that to raise the limit to twenty-five years and open the competition to all students of the Society who have not passed the Minor would result in a much better class of collectors, and would at least double the number of entries.

Harrogate.

THOMAS W. CLEAVE.

THE REVISION OF THE BRITISH PHARMACOPOEIA.

Sir,—I sincerely hope to see Mr. Ince's suggestions re nomenclature adopted. I have noticed the inconsistencies constantly; they are eyesores. I should also like to see substances given Latin names dissimilar to the English where possible, so as to render prescriptions unintelligible to anyone but the doctor and the chemist. I think both medical men and pharmacists will agree that this is desirable. At present a patient can always tell when there is opium in his prescription; alter it to 'theba'um; and he is fogged at once. Antimony should be stibium. Sodii carbonas should be natri carb. Potassium in Latin should be kalium. In many other cases, i.e. pipacocanha and sema, a change at present would be perhaps revolu-

tionary. Latin synonyms might be usefully introduced thus—Tinct. buchu—syn. tinct. baro-sup. Ext. of malt if included should certainly be ext. binae, and not extractum malti. When the '67 cardamon was altered to the '86 cardamomum semia, a good principle was started, which requires further application. Single names for drugs are too empirical. Cubebs should be cibebis fructus; copaibs, copaibus oleo-resinum; saumonium, saumonii gum-resinum; singibor, sing. rhizos; borax should give place to pyroborate of sodium (natri pyroboras, Latin); sinapis to sinapis farina, and many others similarly.

Amongst other desirable changes:—Hydrochlorates of morphone and other alkaloids should be termed hydrocho
rides. Linseed meal, which is never used, should be omitted and crushed linseed (linseed meal) substituted. Oleate of mercury should be linatized as hyd. oleas, not oleatum hydrarg. The same with the oleate of zinc and its ointment. Resins should give way to resinsum. Pulv. scammonii co. should be pulv. scammonii com. as it is now made from scammonia resinum. Petroleum spirit (appendix) would be more systematically called “volatile paraaffin”; it would then fall in line with hard paraaffin, soft paraaffin, and liquid paraaffin (vaseline oil). Cell ung., glyo. plumbi subacet. ung. plumbi so. g., simply so that it may get printed by the side of the other lead ointments. Ether is linatized with a diaphthong, but ethyl is not; better drop the cumbersome e (or if not, then use it for both). When bush (because per cent.) it is usual to say “ether pure, to distinguish from methyalated ether. It would be well, therefore, for the B.P. to follow suit by calling ether—ether purus and the present ether purus—ether absoluta. I think the compilers of the B.P. are a little too timid in adopting systematic names. Arsenni oxidum is a term not much used for the familiar “arsenious,” but neither is acid. arsenicosum, and as the former is more correct it should have the preference officinalis. It is also high time for educated men to drop the term “cotton wool.” How can cotton be wool? We can rise to colicnicum corn, but not to orange pericarp. Essential oils should be uniformly termed otto (otto limonis, etc.). The description of white as white, and yellow as yellow is most ambiguous. Two articles should be inserted, p.m. album and p.m. flavum (exactly as with cerul, alb. and flav.), and the white should be used for all pale ointments, the yellow only where there is a dark constituent.

It would be a great gain if formulas were more frequently constructed with easily divisible quantities, e.g., ung. acidi carbol. 1 to 20 instead of 19 to 1, ung. acidi boric. 1 in 8 instead of 7, p. m. acidi salicylic. 1 in 30, not 28. Many other instances might be mentioned. Recipes printed as it is for ung. cantharidum are somewhat misleading; the quantity of each ingredient ought to be carried out separately. One is apt to look hurriedly and think the ointment is 1 in 7 instead of 8. Heat is not required in making either of the tinctures of quinine. Forms for vapor benzoin and ung. hyd. odor. flav. might well be included. Under proof spirit add “product seven pints, sixteen ounces.” Everyone, of course, is looking for a bold adoption of the metric system, but may I express a hope that no attempt will be made to depart from the principal measures. The difficulty is this—Minims up to fifteen can only be expressed by using fractions of a millilitre or cubic centimetre, or by an immense number of cubic millimetres. Hence the tendency to express by weight. Fractions—especially in prescriptions—are absolutely required because the compound and parts are so easily misplaced. I suggest the division of the millilitre into ten “parvillire” (or “parvils”)—this parvile to take the place of the minims throughout in doses and formulas. Measurement by the sub-divisions of the litre will be more convenient for pharmacists than by the cubic centimetre, as the latter runs into such unwieldy numbers.

DEVONNERSIS.

Weights and Measures.

Sir,—I have just read with pleasure Mr. D. R. Dott’s article in the Pharmaceutical Journal of October 20, on “Weights and Measures,” and I entirely agree with him. I have had years of experience of both methods, and I have on many occasions seen the point put in the wrong place (in prescriptions) in the metric system, as suggested by Mr. Dott as a likely error.

San Remo.

FRANK R. SQUIRE.

Answers to Correspondents, etc.

J. J. HORN.—The title “Graduate in Pharmacy” (Ph.G.) is conferred by several colleges of pharmacy in the United States, after the completion of a definite course of instruction. Sometimes the phrase is used informally to indicate one who has passed the Minor or legal qualifying examination in this country.

"Thymus."—Apparently a water-soluble aniline dye.

"Dental."—We are not aware of any such change in the law. As you surmise, the practice is not legally prohibited, but only the unlawful assumption of title. At the same time, unregistered persons cannot recover fees for operations, attendance, or advice.

OBITUARY.

Notice has been received of the death of the following:—

On August 30, 1894, at Goodwood, Australia, Desir Monchery Renaud, Pharmaceutical Chemist, formerly of Port Louis, Mauritius. Mr. Renaud was a life member of the Society, with which he had been connected since 1860.

On October 13, Joseph Philips, Chemist and Druggist, Wadebridge. (Aged 69.)

On October 15, Austin S. Grieve, Pharmaceutical Chemist, Birmingham. (Aged 59.)

On October 19, Arthur Reeke, Chemist and Druggist, Edinburgh. (Aged 49.)

On October 20, Patrick Dalgarno, Chemist and Druggist, Southampton. (Aged 61.)

On October 24, Francis 0. Carnaby, Chemist and Druggist, Blyth. (Aged 37.)

Diary of the Week.

SATURDAY, OCTOBER 27.

Pharmaceutical Football Club v. Cowley Athletic, at New Barnet, at 3.15 p.m.

THURSDAY, NOVEMBER 1.

Chemical Society, at 8 p.m.

“The Action of Nitric Oxide on Sodium Ethylate,” by G. W. Macdonald and D. Orme Mason.

Linsenas Society of London, at 8 p.m.

On Mediterranean and New Zealand Retina, and a Fenestrate Bryozoa,” by A. W. Water.

Liverpool Pharmaceutical Students’ Society, at 8.30 p.m.

Chemical Association, at 8.30 p.m.

“Recent Advance in Photography,” by E. W. Hill.

Presidential Address, by W. L. Currie.

Adjourned Discussion on J. A. Russell’s Motion.

FRIDAY, NOVEMBER 2.

Quellet Microscopical Club, at 7 p.m.

Exhibition of Objects.

NOTICES TO CONTRIBUTORS.

**Communications should reach the Editor, Drug Department, 17, Bloomsbury Square, W.C., before noon on Wednesday, if publication is desired in the next issue of the Journal; though this cannot always be guaranteed. Matter intended for publication must be written on one side of the paper only, and be authenticated by the name and address of the writer; necessarily for publication, but as a guarantee of its being printed.**

COMMUNICATIONS, LETTERS, etc., received from Messrs. Clegg, Cracknell, Gibson, Hulson, Kemp, Kidd, Salt, McLoughlin, Mersen, Morley, Mumbray, Rawling, Robinson Smith, Squire, Summer.
Photographic Developers.

G. A. Le Roy observes that the reducing power of alkaline peroxides, or of hydrogen peroxide, in aqueous solution, is capable of exerting itself upon the bromide or chloride of silver in gelatin emulsions employed on dry photographic plates, after those salts have been exposed to the action of light. The intensity of the reduction effected is proportional to the extent of the luminous action upon the exposed surface. Such solutions, therefore, are capable of revealing latent photographic images obtained by means of dry plates. At the same time the alkaline peroxides are inferior in that respect to the developing agents usually employed in photography, and require the time of exposure to be prolonged. Moreover, the developed image, formed by metallic silver and its oxides, loses its intensity to some extent in the hyposulphite or sulphocyanide solutions used as fixing baths (Comp. rend., cxix., 507).

A. Trillat, having demonstrated that the proximity of a cloth moistened with a weak solution of formic aldehyde serves to arrest the putrefaction of meat, has based a system of disinfection upon this property, and now publishes the results of a later series of experiments on the disinfection of rooms. The apparatus employed is a kind of lamp capable of transforming daily about five kilograms of methyl alcohol, by incomplete combustion, into the vapour of formal, the yield of the latter being about 25 per cent. of the alcohol consumed. The lamp, of which an illustration is given, consists of a copper cylinder, 20 cm. high by 16 cm. wide, which rests upon a spirit reservoir of two litres capacity, and is covered at the top by a lid. At each extremity of the cylinder there is a row of draught-holes covered by a similarly perforated movable ring, so that the entry and exit of air can be easily regulated as in a Bunsen burner. The lamp has a large round wick, about three or four centimetres above which is fixed a piece of platinum gauze. In use, the lamp is sighted, and when the platinum gauze in the cylinder has been warmed for a few seconds the draught-holes are closed. It is not long before the flame is extinguished and if at the precise moment the draught-holes are opened wide the platinum gauze becomes incandescent. With a little manoeuvring the supply of air may be so regulated that a dull red incandescence is maintained, and the lamp then continues to act, burning without a flame. The vaporised methyl alcohol is instantaneously oxidised to formic aldehyde on coming in contact with the platinum, and the aldehyde vapour escapes through the upper draught-holes. It was found that the action of the vapour was most effectual in the upper part of rooms, and that in a room of 20 m² all germs were killed by it in eight hours, the weight of methyl alcohol burned being 0·200 Gm. In the course of further experiments it was proved that the presence of water mitigates the antiseptic action of the formal in a degree that was proportional to the humidity of the atmosphere. Surgical instruments and metallic articles, as well as cloth, etc., were not deteriorated by the action of the formal vapours, though certain colours were affected, materials dyed with rosaniline derivatives, for example, becoming somewhat violet in tint. The odour of the formal is noted, and may be removed from rooms by strong currents of air or by exposing open vessels containing ammonia (New. Rev., x., 464).

Sodium

A. Joannis has obtained a compound to which he ascribes the formula \( \text{PH}_3\text{K} \) and Potassium Phosphides

ammonium. This potassium phosphide occurs in fine white needles, and is analogous to potassium azide, \( \text{NH}_3\text{K} \). In a similar manner he was able to prepare sodium phosphide, \( \text{PH}_3\text{Na} \), from soda-ammonium, as a white solid. The action of heat decomposes the compounds, as follows:—

\[ 3\text{PH}_3\text{K} = 3\text{PH}_2 + \text{PK}_3 \]

Water also decomposes them, with liberation of phosphoretted hydrogen, and when ammoniacal solutions containing them are treated with nitrous oxide, a volume of nitrogen is liberated equal in volume to the nitrous oxide employed (Comp. rend., cxix., 507).

Mercury Sulphates

R. Varet gives some interesting illustrations of the interdependence of chemical and physical factors. Thus, he shows that when water acts upon sulphate of mercury more heat is produced than with any other reaction of the latter, and that this exothermic reaction explains why the salt is decomposed into free acid and a basic salt, since in the case of alkaline or metallic salts which are not decomposed by water the action is endothermic. Again, whilst sulphuric acid displaces the hydrocyanic acid in potassium cyanide, without precipitation and with the disengagement of heat which corresponds to the thermal preponderance of the first acid relatively to the base, in the case of mercury it is the hydrocyanic acid which completely displaces the sulphuric acid with a similar disengagement of heat. This reversal of the ordinary conditions between the two acids is precisely similar to what occurs with hydrocyanic and hydrochloric acids, and is in that case explained in the same way by the thermal preponderance of the former acid. Sulphuric acid is also more or less completely displaced from sulphate of mercury by hydrochloric acid, for the same reason (Comp. rend., cxix., 684).

Antimony Sulphide

H. Baubigny discusses the question whether the compound formed by the action of an alkaline hypophosphite upon antimony trichloride is a sulphide or, as generally supposed, an oxy-sulphide, and gives the results of experiments performed with a view to solving the problem. He concludes that the colouring matter of the so-called vermilion of antimony, formed by the action of sodium hypophosphite on tartar emetic in the presence of tartaric acid, in so far as it is a definite chemical compound, is the ordinary sulphide, \( \text{Sb}_2\text{S}_3 \). If it possesses a special tint that, it is asserted, is due to the conditions under which the compound has been prepared. As to the compound prepared from antimony trichloride in the absence of tartaric acid, it if contains oxygen it is only as an admixture, in the form of oxychloride (Comp. rend., cxix., 697).
A. Renard describes a novel hydrocarbon occurring among the products of distillation of tar, which is probably a member of the aromatic series. When purified it is a colourless liquid, boiling at 264°-267°. Its density at 0°C. equals 0.9419, its refractive index is 1.507, and it is without action on polarised light. Its analysis and vapour density indicate its formula as \( C_9H_{18} \). Exposed to air it becomes brown in colour, but hydrochloric acid does not affect it. With bromine it forms colourless crystals of a tetrabromide derivative, \( C_9H_{18}Br_4 \), and an unstable bistribromide, \( C_9H_{18}Br_6 \), may also be prepared. A nitro-derivative, \( C_9H_{18}NO_3 \), is formed by the action of fuming nitric acid upon an acetate solution of the hydrocarbon, and a sulphonic derivative by the action of sulphuric acid. The latter when separated, distilled, and otherwise purified, yields about 19 to 20 per cent. of a saturated hydrocarbon that boils at about 250°-255°, corresponds to the formula \( C_9H_{18} \), and is unaffected by the strongest acids. The sulphonic acid remaining in solution may be separated by precipitating it as an ammoniacal salt, \( C_9H_{18} \cdot 2H_2O \cdot 3NH_4 \cdot SO_4 \cdot 2Ba \). The last reaction noted of the hydrocarbon, \( C_9H_{18} \), is the very marked blue coloration produced on treating it with a mixture of sulphuric acid and alcohol. This, according to Maquenne, is characteristic of the aromatic hydrocarbons. The partial transformation of the new compound, when treated with sulphuric acid, into a saturated hydrocarbon may be compared with the transformation of heptene, \( C_7H_{14} \), into toluene hexahydride, and it may possibly be correct to regard it as bi-heptynyl, \( C_9H_{18} \cdot H_2 \), or bi-tolyl octo-hydride, \( (H_2 \cdot C_6H_5)_2 \cdot H_2 \). This formula also accords with the transformation of the compound into a saturated hydrocarbon or bi-tolyl dodecacylhydride \( (H_2 \cdot C_6H_5)_2 \cdot (C_6H_5 \cdot H_2) \), by fixation of four atoms of hydrogen (Comp. rend., citix., 652).

H. Causse shows that, even in dilute solutions, nitric acid in combination with bismuth oxide converts salicylic acid into a disalicylic acid which is capable of forming a series of nitrosalicylates, the appearance of which varies with their composition. Thus, the neutral \( \beta \)-nitrosalicylate of bismuth \( (C_6H_5 \cdot NO_2 \cdot OH \cdot CO_2) \cdot Bi + 2H_2O \) forms colourless needles; the basic \( C_6H_5 \cdot NO_2 \cdot O \cdot CO_2 \cdot BiOH \cdot H_2O \) occurs as citron yellow needles; and the sub-\( \beta \)-nitrosalicylate of bismuth \( (C_6H_5 \cdot NO_2 \cdot OH \cdot CO_2) \cdot BiO \cdot H_2O + H_2O \) precipitates in needles of a reddish-orange colour. This property of the acid seems to be owing to the presence of the group \( NO_2 \) in its molecule. The red coloration of bismuth salicylate, supposed to be due to the presence of iron, is alleged to be caused by the presence of a nitrosalicylate. These statements should be of interest to dispensers (Comp. rend., citix., 690).

H. N. Warren suggests the substitution of magnesium for the zinc rod in the Daniel's voltaic cell, on account of its greater reducing action, and the use of cupric chloride instead of cupric sulphate in the outer vessel, because of its greater solubility in water, and the possibility of making the solution so as to offer less resistance. This solution should be rendered strongly acid by means of hydrochloric acid, and will be very slowly decomposed. The porous pot should be charged with a strong solution of ammonium chloride which dissolves the magnesium uniformly, forming a double chloride, and at the same time prevents local action. With these modifications it is said a voltaic arrangement may be constructed giving a voltage equal to a nitric acid battery or bichromate cell (Chem. News, lxx., 179).

Phosphorescence of Prestressed Glass (pale p.) have been undertaken by Blea'i.

Temperatures. Pictet, the intention being to determine the specific action of a considerable lowering of temperature upon the brilliancy of certain bodies which shine in the dark after having been exposed to sunlight. Tubes of glass filled with the powdered sulphides of calcium, baryum, strontium, etc., all substances which possess the property of phosphorescence in a high degree, were exposed to the solar rays and afterwards proved to be luminous in the dark. This was done in such a way as to fix upon the surface of the substance some value of the progressive diminution of the emitted light, and the time also was noted during which the light was strong, strong, and weak respectively. The tubes were next placed in bright sunlight for one minute and then suddenly introduced into a double-walled glass cylinder, the interspace of which was filled with nitrous oxide at -140° C. In about five or six minutes the temperature of the tubes was about -100°. They were then withdrawn and, when observed in a perfectly dark chamber, no luminosity whatever perceptible. As the tubes recovered their normal temperature, however, the phosphorescence returned, without the exciting agency of either the sun's rays or diffused light. These results were proved to be general for all phosphorescent substances employed. The complete suppression of phosphorescence at very low temperatures having been thus demonstrated, attempts were next made to fix the limits of temperature at which the luminosity ceases to be visible. Tubes of phosphorescent powder were thus heated and rapidly conveyed to the dark chamber, and partially immersed in alcohol cooled to -75°. The phosphorescence disappeared completely from the portion of the powder contained in the part of the tube immersed, when its temperature was reduced to -60° or -70°, but after immersion for more than half an hour the light returned spontaneously as the effects of cooling wore off. The phenomena were alike with all the phosphorescent substances examined. The blue, green, or orange light emitted by different metallic sulphides tended in such a way to change to an earthy yellow before being extinguished. It was proved by repeated experiments that condensed moisture on the outside of the tubes did not in any way influence the extinction of the phosphorescent light, or affect any of the observed results. It appears certain, to Pictet, that the production of phosphorescent light requires a certain movement of the constituent molecules of bodies. When these are frozen and the calorific oscillatory movements are checked, the luminous waves are not produced and the phosphorescence disappears accordingly (Comp. rend., citix., 527).
Wallach has determined the constitution of limonene from the following considerations:—Limonene reacts with bromine, forming limonene tetrabromide, which is decomposed by sodium methylate thus:

\[ C_{10}H_{14}Br_4 + 3NaOH \rightarrow C_{10}H_{14}BrO_3 + 3NaC_2H_5OH. \]

The product can be made to yield the methyl ether of carvyl by treatment with silver acetate and acetic acid, and by treatment with hydrobromic acid dipentene tetrabromide results. Since carvyl and dipentene can be obtained from limonene tetrabromide, that compound must have one of the following formulas:

\[ \begin{align*}
\text{CH}_3 \text{Br} & \quad \text{CH}_3 \text{Br} \\
\text{H}_2 & \quad \text{H}_2 \\
\text{HBr} & \quad \text{HBr} \\
\text{H}_2 & \quad \text{H}_2 \\
\text{C}_6\text{H}_4 & \quad \text{Br} \\
\text{Br} &
\end{align*} \]

The third is considered an unlikely configuration from analogy. By acting on I. with sodium methylate, no product could result which would yield carvyl or dipentene derivatives on treatment with silver acetate or hydrobromic acid. But II. would yield the other, and is capable of forming carvyl ether and dipentene tetrabromide. Nor terpeneol yields a tetrabromide of known composition, and the three bromine atoms in its formula are in the same position as those presupposed for limonene tetrabromide, whilst the compound yields carvyl ether by proper treatment, identical with carvyl ether obtained from limonene. Thus the formula for limonene tetrabromide and limonene are confirmed (Annalen, 381, p. 127).

**Lysinid.**

At the Naturforscherversammlung in Vienna, Ladenburg described under this name a basic compound obtained in the state of hydrochloride by heating ethylene diamine hydrochloride with sodium acetate. The composition of the free base is C\(_{2}H_{4}N_{2}\), and its constitution is represented by the formula:

\[ \begin{align*}
\text{CH}_2 & \quad \text{N} \\
\text{H} & \quad \text{C}_2\text{H}_4\text{N} \\
\text{CH}_2 &
\end{align*} \]

The water solution of this base is described as having a remarkable power of dissolving uric acid, and the application of lysinid in the treatment of diseases arising from secretion of uric acid is being investigated. The substance is described by Grawitz (Deutsche med. Wochenschr., 1894, p. 798) as crystalline, of a light red colour, readily soluble in water, and having a peculiar taste. It is given in doses of from 15 to 30 grains daily, dissolved in arabinoid acid water. The manufacture of lysinid is being carried out at the Höchst chemical works.

In a paper in the Bulletin of the Belgian Microscopical Society (1894), M. Clautierau describes the mode of distribution of the alkaloids in a variety of plants, which he arranges under five types, viz.:(1) In a layer of cells lying between the endosperm and the true testa (Atropa belladonna, Datura stramonium, Hyoscyamus niger); (2) in two layers, especially in the outer one, between the endosperm and the pericarp; also, to a smaller extent, in the epiderm, and in the cells which accompany the vascular bundles (Conium maculatum); (3) in the endosperm, especially in its peripheral cells (Aquintum napellus, Delphinium staphyagria); (4) in all the cells of the endosperm, and to a smaller extent in those of the embryo (Brachyos sui-zononis); (5) apparently in the cotyledons and plumules (Lupinus albus). The alkaloids take active part in germination, but are formed in the seedling by decomposition of the albuminoids. In Papaver somniferum the amount of alkaloids decreases as the seeds ripen, and this is accompanied by an elimination of nitrogen. Their chief function here appears to be to protect the plant from consumption by animals.

**Formation.**

In a paper in the Programme der Realschule vor der Holstenith in Hamburg, Herr G. Mielke traces the formation of tannins in plants through phenols, phenol-alcohols, and aldehydes; they occur, in chemical combination with sugar, as glucosides, and play an important part in vegetable economy, since they are the indispensable material for the production of lightening substances. They are never formed out of albuminoids, and are not nutritive substances; they can take part in metabolism only when they revert to their previous stages by absorption of water. Resins and essential oils are probably the final results of the metamorphosis of tannins.

**Action of Light.**

Association and recently abstracted in the 'Annals of Botany,' Professor J. R. Green states that the results of the experiments that have so far been conducted show that light, whether solar or electric, exercises a destructive effect upon diastase, which continues after the exposure to light is discontinued, the exposed solution gradually becoming weaker until it possesses no diastatic power. This deleterious influence is confined to the rays of the violet end of the spectrum, the others being slightly favourable rather than destructive. Part of the solution so found to be affected by light-rays was kept in darkness and maintained its diastatic power unpimpaired for more than a month, by which time the exposed portion of the solution, which had also been kept in darkness after an exposure of from two to eleven days, possessed no power to act upon starch. The experiments were performed on an extract of malt prepared by infusing ground malt with water or salt solution, and the results would seem to indicate the desirability of carefully protecting malt extracts from the action of light. A comparison of the diastatic power of fresh malt extract with that of similar material exposed in the pharmacy for varying periods suggests itself as an investigation of direct pharmacological and medical interest. At the same time it yet remains to be proved that the diastase is the chief or only active agent in malt extract. The colouring matter of the barley-husk has been proved to act as a screen which preserves the diastase from the destructive effect of light, whether it is dissolved.
In the extract made from malted barley or used separately as a seerent placed before the cells in which exposure is made.

Wheat and Rye Starch. E. Guemes points out that these starches possess very similar character and it is difficult at times to say decidedly that a given sample consists of one rather than the other. To distinguish the two kinds he recommends that a little of the material be mounted in water for examination with the microscope. The wheat starch will then be seen to contain comparatively few split grains, which possess an isolated fracture situated near the edge or proceeding from the centre to the circumference. In the case of rye starch the split grains are numerous and possess a star-shaped fracture with three or four branches, apparently originating in the centre of the grain and radiating towards the edge. Some grains may also be found which have only a linear crack, but this will be larger in the centre of the grain than towards the edges, just the reverse of what occurs in wheat (Bull. de Pharm. de Bordeaux, xxiv., 289).

The Pharmaceutische Centralblatt mentions several preparations of a secret nature which have recently been introduced under the following names:—Chrotool, for the treatment of skin diseases; Collasin, a kind of varnish, preferable to collodion, for application to the skin; Brassicoen, a remedy for headaches, apparently consisting of camphor, peppermint oil, ether, oil of mustard, and alcohol. As a remedy for sea-sickness, Anachypticum is recommended, and somewhat vaguely described as a mixture of a double tartrate with sodium bicarbonate, magnesium, quinine, and sal ammoniac. Boral is a compound of aluminum borate and tartrate; Cutal, an aluminum boro-tannate, containing 10-71 per cent. boric acid, and 76 per cent. tannin.

Leaves of Scopolia contain scopalamine which has been investigated by Mr. J. B. Nagelvoort, who has grown the plant for the purpose of identifying its alkaloid with commercial hyoscine. The results obtained were totally negative, but it is suggested that this isolated instance is scarcely sufficient to settle the question, especially since it is known that cultivated plants are frequently poorer in alkaloid than those growing wild. (American Journal of Pharmacy, xxiv., 431.)

Purification of Water by Green Plants. The prevalent idea that green plants (flowering plants and algae) growing in running water add to its impurity and unfitness for drinking purposes, has long been shown to be erroneous. As long as they are in a growing condition they can only tend to purify the water by giving out oxygen into it. In a paper in the Archives für Hygienes (1894, No. 2), Dr. T. Bokorny maintains that aquatic bacteria also have a share in the purification of the water as long as it contains a considerable quantity of organic matter. A series of experiments carried on by the author showed that algae are capable of decomposing fatty acids such as butyric and valerianic, as also glucose, leucin, and tyrosin.

MANUFACTURE OF ESSENTIAL OILS.

The essential oil industry has derived considerable advantages from the progress in the chemical investigation of essential oils which has taken place during the last few years. The term which used often to be applied to the supposed workmanlike manufacture of an essential oil, that it had been turned out according to the rules of the art ("lege artis") is now no longer suitable.

A mode of manufacture based upon intelligent principles has replaced rule-of-thumb work; craftsmanship has been ousted by science, which, in teaching us the physical and chemical properties of an oil, indicates at the same time ways and means of improving its manufacture. Nowadays each raw material requires its own method of distillation, every crude oil its own special mode of rectification. The processes of preparing similar oils are sometimes altogether different in principle, while in other cases slight deviations in method are sufficient to bring about important improvements in the manufacture.

The fact that freshly distilled oils have a disagreeable subsidiary odour, the so-called "still-smell," was formerly looked upon as quite a matter of course, but it is now known to indicate either want of knowledge in the process of distillation or gross carelessness. The fresher the oil, the purer it should be, and vice versa. Freshly rectified oil of caraway should smell just as aromatic and agreeable as the freshly crushed seed. If, as a result of defective distillation, an oil has once acquired the well-known mordant sharp odour, no amount of exposure of the oil to the air will remove this entirely; but, on the other hand, the oil, if kept in this condition, all the more rapidly falls a victim to the fate of almost all essential oils, viz., recombination or other decomposition, without having ever been really pure in odour or taste. —Schimmel’s Bericht.

DEODORISING RECOVERED ALCOHOL.

BY EDWARD A. KADEL.

Here is a method that, with slight modifications, gives splendid results in my hands. I have not yet found an alcohol so vile that I failed to purify so as to render it fit for employment in general manufacturing.

The alcohol is first treated with caustic soda; for alcohol recovered from drugs like arnicas, buchs, cubebes, etc., one ounce to each gallon is employed. After standing for two to five days it is distilled in a water-bath or steam-jacket kettle. The alcohol first passing over must be returned to the still. This is continued until the odor is either changed or lost. Usually this distillation leaves an empyreumatic and sometimes a soapy odor to the alcohol. It is then redistilled with potassium permanganate; the quantity to be used can be determined by experience alone, alcohol recovered from the same drug at different processes requiring different proportions; usually one to four drachms to a gallon is employed. Thus treated it is generally clean enough for reemployment for manufacturing purposes, seldom pre-
ducing any coloration with hydric sulphate. If further purifying is desired again distil with the permanganate and filter through animal charcoal, but unless the charcoal is freshly prepared this is useless. If I have not fresh charcoal, I add a small quantity of distilled water and distil again after the second treatment with the permanganate.

From the standpoint of economy this process certainly is unobjectionable. I employ a five-gallon still of my own construction, a fair average of three gallons an hour by water-bath being its working capacity. Time, gas, and material, I find, are fully compensated for, and in laboratories equipped with steam the cost of purifying is reduced to a minimum. The process requires no attention after it is once under way; I seldom go near the still after complete automatic action has been secured.—Indiana Pharmacist and Western Druggist.

**ABSORPTION-SPECTRUM OF CHLOROPHYLL.**

In two papers in the *Aeta Horti Petropolitani* (1893 and 1894), M. N. Monteverde states that the absorption-spectrum of living leaves consists of seven bands and a terminal absorption. The degree of intensity of the former is as follows:—I.a, VI., V., I.b, II., III., IV. The spectrum of the alcoholic extract differs only in the absence of I.b, and in a slight shifting of all the bands. Instead of first boiling in water, as most other observers have done, he extracts the chlorophyll at once with cold 95 per cent. or absolute alcohol. The alcoholic extract always contains two green and two yellow pigments. The two latter are separated by precipitating by baryta and extracting the precipitate by alcohol. If this extract is then agitated with petroleum ether, the carotin is dissolved in the ether, the xanthophyll in the alcohol. The two green pigments are termed by the author amorphous and crystalline chlorophyll. Their relative amount differs greatly in different leaves. Amorphous chlorophyll is characterised by the complete absence of band V. from its spectrum. It is more soluble in benzoin, petroleum ether, and carbon bisulphide than in alcohol. Crystalline chlorophyll may be obtained from certain leaves (e.g., *Dianthus barbatus*, *Dahlia variabilis*) simply by evaporating the alcoholic extract and purifying the crystals by water and benzoin. They are completely insoluble in petroleum ether, carbon bisulphide, and ordinary benzoin; soluble in alcohol, ether, chloroform, and pure benzoin. It is probable that living leaves contain this kind only of chlorophyll. The alcoholic extract of *Oscillatoria filamentosa* contains carotin, phycocyanin, and both kinds of chlorophyll. Etiolated leaves contain, besides xanthophyll and carotin, a pigment to which the author gives the name "protochlorophyll." It displays a distinct red fluorescence, and exhibits a line in its absorption-spectrum corresponding to band III. of chlorophyll, and a second characteristic band at some distance from band II. of chlorophyll. Band I. is entirely wanting. The spectrum attributed by Pringsheim and Teobrich to etiolin is probably a combination of the spectra of a modified chlorophyll, of protochlorophyll, of carotin, and of xanthophyll.

**THE PROPOSED IMPERIAL PHARMACOPOEIA.**

By the courtesy of the Registrar of the Pharmacy Board of Victoria, we are enabled to present to our readers the recommendations of the Victorian Branch of the British Medical Association, the Pharmacy Board of Victoria, and the Pharmaceutical Society of Australasia, concerning the forthcoming new Pharmacopoeia. A summary of these recommendations was given in the Journal for September 29 (see p. 258).

**RECOMMENDATIONS ON NEW PHARMACOPOEIA.**

The following is the Report of the Committee, as finally revised, and approved at a meeting, on August 15, 1894:

In view of the proposed revision of the British Pharmacopoeia, and upon the receipt of a letter from the Hon. the Premier, inviting their co-operation, the Victorian Branch of the British Medical Association appointed a Sub-Committee to deal with the matter of recommendations re the new Pharmacopoeia. This Sub-Committee associated with it Baron Sir F. von Mueller, Government Botanist; Messrs. J. Bosisto, F. Davenport, H. W. Potts, Pharmaceutical Chemists; and with Messrs. C. R. Blackett and G. Swift, representing the Pharmacy Board of Victoria; and R. P. Francis, representing the Pharmaceutical Society of Australasia. The following Report is the result of their conjoint labours, and is to be taken as representing their combined recommendations.

Upon the following points there was unanimous agreement:

1. That in the case of the drugs mentioned in Appendix A, which there is the authority of Baron von Mueller for asserting can be grown in Victoria equally as well as in the present recognised official parts, the present restrictions as to growth and preparation be removed so far as Victoria is concerned; and that *Duboisia* be introduced as suggested by Baron von Mueller.

2. That in lieu of the present unsatisfactory official formulae for eucalyptus and preparations, the formulae mentioned in Appendix B, which have been drawn up by Mr. Bosisto, C.M.G., be substituted.

3. That the metric system of weights and measures be adopted.

4. That failing the adoption of the metric system, the strength of the liquors of the alkaloids revert to gr. j in 3 ij.

5. That the drugs and preparations mentioned in Appendix C, being unused in practice and unnecessary in therapeutics, be omitted from the new Pharmacopoeia.

6. That attention be drawn to the unsatisfactoriness of wax and paraffinum durum as bases for ointments; that all the properties required in such ointments can be obtained from suitable combinations of adepe lane and paraffinum molle; and that cocoa butter be recognised as the sole basis for all suppositories.

7. That in regard to tests, such as those used in chloroform, chloral, carbolic acid, cresate, etc., there be introduced such improvements as are now generally accepted; and that there be mentioned with the test the specific impurity which it is destined to show the presence or absence of.

8. That the standardisation of drugs and prepara-
9. That the drugs and preparations mentioned in Appendix D be included in the new Pharmacopoeia.
10. That the list of tabellae be increased by the addition of those for hypodermic use mentioned in Appendix E; that the troches of the latest edition of the London Throat Hospital be made official; and that cigarettes be introduced of cubeb, arsenic, cannabis indica, and stramonium.

11. That, like the decoctions, all the infusions be made up to a definite quantity.
12. That, so far as practicable, by a revision of the preparation agents, by the extension of capsules, tabellae, troches, and the like, and by the introduction of suitable compressed tablets, cigarettes, and the like, there be a sustained attempt made after such improvements in flavouring and dispensing as tend to the more palatable and elegant administering of drugs generally.

Upon the question of dosage, the pharmacists preferred to leave the matter in medical hands, although they agreed generally with the following recommendations of the medical Sub-Committee.

13. That in the cases mentioned in Appendix F the minimum official dose should be lessened.
14. That in the cases mentioned in Appendix G the maximum official dose should be increased.
15. That in the cases mentioned in Appendix H the inconsistencies in dosage should be rectified.

16. That the dosage be given in the cases mentioned in Appendix I.
17. That it be required that excessive dosage not be prescribed by the pharmacist, unless and until it has been intimated, or otherwise drawn attention to by the prescriber.

Signed,

J. W. SPRINGTHORPE, M.A., M.D., Melb., M.R.C.P. Lond., Lecturer on Therapeutics in the University of Melbourne.

F. H. COLE, M.B., Melb., Lecturer on Pharmacy in the College of Pharmacy, Melbourne.

P. W. FARMER, M.B., M.B., Lecturer on Chemistry in the College of Pharmacy, Melbourne.

C. R. BLACKETT, F.C.S., President of the Pharmacy Board of Victoria; Government Analyst.

APPENDIX A.

Medicinal plants in the British Pharmacopoeia which grow satisfactorily in the Colony of Victoria:—

Aconitum napellus, Linné.

Atropa belladonna, Linné.

Borberis vulgaris, Linné.

Capsicum frutescens, Linné.

Carum carvi, Linné.

Cinnamonum camphora, Linné.

Cockearia armaricia, Linné.

Panicum officinale, Allioni.

Praunus ornus, Linné.

Gelsemium nitidum, Richard.

Centia bona, Linné.

Glycyrrhiza glabra, Linné.

Hyoscyamus niger, Linné.

Juniperus communis, Linné.

Juniperus sabina, Linné.

Lactua virosa, Linné.

Lavandula vera, De Candolle.

Lebbia ininata, Linné.

Mentha piperita, Linné.

Mentha viridis, Linné.

Papaver somniferum, Linné.

Anthemis nobilis, Linné.

Convolvulus coccineus, Linné.

Coriandrum sativum, Linné.

Cucumis colocynthis, Linné.

Cytisus scoparius, Link.

Delphinium staphyleagria, Linné.

Digitalis purpurea, Linné.

Reballium olarium, Rich.

Pimpinella anisum, Linné.

Pistacia lentiscus, Linné.

Podophyllum peltatum, Linné.

Polygala senega, Linné.

Prunus laurocerasus, Linné.

Rhamnus frangula, Linné.

Rhew psalmatum, Linné.

Ricinthus communis, Linné.

Rosmarinus officinalis, Linné.

Ruta graveolens, Linné.

Sambucus nigra, Linné.

Thymus vulgaris, Linné.

Urginea reptans, Steinheil.

Veratrum viride, Solander.

Ferdinand von Mueller.

Mr. Bosisto also writes as follows:

Opium (Papaver somniferum).

This plant grows luxuriantly in Victoria, and yields morphine fully equal to that grown in Asia Minor.

After the words "Asia Minor" in the B.P., we would recommend to add "or Victoria, Australia." We have no evidence of its growth in the other Australian Colonies.

Essential Oils.

The climate of Australia is well adapted for, and produces to perfection, essential oils from um- belliferous plants, viz., anise, caraway, coriander, dill; also chamomile, lavender, lemon, peppermint, rosemary, and rue. We therefore recommend that after the words "oil distilled in Britain," the following words be added, "or in Australia."

Regarding Duboisia, Baron von Mueller advises as follows:

Duboisia myoporoides, R. Brown.

Duboisine: Prepared from leaves with their branches in the manner of nicotine. Yellowish oil-like liquid, volatile, lighter than water, of strong narcotic odour, of pronounced alkaline reaction, completely neutralised by acids, dissolves in all proportions in water, alcohol, or either precipitates ferrous oxide from sulphate of iron, dissolves without colouring in concentrated acids. Its hydrochloride, in a weak aqueous
solution, is precipitated by iodide of potassium, the iodides of potassic-mercury and of potassic-bismuth, and by tannic acid, not by many other alkaloid reagents tried. Duboisine is in many respects allied to nicotine, but that alkaloid is distinguished by specific gravity, its less powerful odour, by its hydrochloride in a diluted aqueous solution being precipitated by phosphomolybdate of sodium, picric acid, and chloride of platinum (F. von Mueller and L. Rummel, in Wittstein’s “Organic Constituents of Plants,” p. 338—F. v. Mueller's translation, with additions, 1878). The sulphate of duboisine is lamellar and yellow.

Dose, 1-120th—1-30th of a grain internally. In ophthalmic applications, 4 grains to an ounce, when only one or few drops are required; otherwise more diluted.

Tincture of Duboisia myoporoides.

Of the cautiously dried herb, two ounces and a half to a pint of proof alcohol, therefore, of the strength of tinct. aconiti, coni, digitalis, hyoscyami, lobelii, stramonii, of the B.P. (unless the lesser concentration of tinctura belladonnae, dried leaves one ounce, to a pint of proof spirit of wine, be preferred).

Dose—1 to 40 minims.

Unguentum duboisinae.

One part of duboisine to 500 parts of paraffinum molle. It is not practicable to prepare an extract of Duboisia, as the active principle, the alkaloid, is volatile.

Duboisia hopwoodi, F. v. M.

Pit urine (C₉ H₅ N). Alkaloid closely allied to duboisine, prepared in similar manner. (The mode of preparation and elucidation of characteristics have been described by Professor Liveridge.) The alkaloid is still more powerful than duboisine.

Duboisia teichardti, F. v. M.

This plant is nearer allied to D. hopwoodii than to D. myoporoides. It seems the most powerful of all three, as last year ascertained at our Alfred Hospital.

Ferdinand von Mueller.

APPENDIX B.

Oleum Eucalypti.
The oil distilled by aid of steam from the fresh foliage of Eucalyptus globulus Labill. and the Mallee eucalypti, comprising Eucalyptus uncinatea Tarr., Eucalyptus oleosa and E. gracilis F. v. M., Eucalyptus incrassata Labill.

Characters and Tests.—It has an aromatic odour, which varies in the different species, and a spicy and pungent flavour; pale straw colour. It is neutral to litmus paper. Specific gravity not below 0-910. Rotates polarised light to the right. Should not give the phellandrene re-action.

Tinctura Eucalypti, B.P.C.

Eucalyptol (Cineol), C₁₀H₁₆O.

Obtained in different proportions from various species of Eucalyptus.

Characters and Tests.—Colourless. It is liquid at ordinary temperatures, but forms crystals at —12° C. to —22° C., re-melting at —1° C. Specific gravity not below 0-920.

Dose—Two to three minims on loof sugar or in milk.

Inhalation, one drachm to the pint of water.

Gummi Eucalypti rostrato (Eucalyptus kino).

The natural indurated exudation obtained from the true red gum tree of Victoria. The species E. rostrata is met with throughout the greater part of Australia in moist valleys and river flats. The ruby-coloured exudation from the wood, termed red gum, is entirely soluble in cold water or proof spirit. It is employed throughout Australia as a delicate mucilaginous astringent of considerable power.

Incompatibles—The alkalies and the metallic salts.

Dose—4 to 6 grains.

Tinctura Eucalypti rostrato.

Rostrata red gum in coarse powder......2 oz.
Oil of eucalyptus..........................2 dr.
Proof spirit ..................................1 pint.
Macerate for 48 hours, with occasional agitation; strain, filter, and add sufficient proof spirit to make one pint.

Dose—60 minims.

Syrupus Eucalypti rostrato.

1. Rostrata red gum ......................24 oz.
2. Water, pure, boiling ................10 oz.
3. Loof sugar .........................22 oz.
4. Oil of eucalyptus .....................1 dr.
5. Acacia mucilage .....................1 oz.

Dissolve 1 with 2, unite 4 with 5, add 3, and make syrup.

Dose—60 to 120 minims.

Suppositoria Eucalypti rostrato.

Powdered gum rostrato ...................5 grs.
Extract aux vomica ........................1 gr.
Oil of theobroma q.s. to make one suppository.

Trocchi Eucalypti rostrato.

Rostrata gum in powder ................720 grs.
Refined sugar .......................25 oz.
Gum acacia ..............................1 oz.
Mucilage of gum acacia ............2 fl. oz.
Distilled water, a sufficiency.
Mix the dry ingredients, add the mucilage and water to form a proper mass. Divide into 720 lozenges, and dry in a moderate temperature.

Unguentum Eucalypti (Ointment of Eucalyptus).

Fresh leaves of Eucalyptus amygdalina ....4 parts.
Benzoeated lard .........................5 parts.
Melt the lard on a water bath, add the well cut up leaves, and digest for two hours; then remove the mixture and express through calico.

The Committee is indebted te Baron von Mueller for the identification and nomenclature of the different species, and to Mr. W. P. Wilkinson for a review of the tests recommended.
### APPENDIX C.

**Drugs and Preparations to be omitted—**

Aeostum. Armoracis radix.

Cuspariae cortex.

Extract. taraxaci liquidum.

Farina tritici.

Granati radiicae cortex.

Hemidesmi. radix.

Larici cortex.

Nectandrae cortex.

Oleo-resina cubbeae.

Rhoadas petala.

Tinct. croci. Tabaci folia.

Vinum Rhei.

### APPENDIX D.

**Drugs and Preparations to be made official—**

Chlorum camphorae. Elixir cascarae sagrad.

The foregoing as in the unofficial formulary of the B.P.C. 1887.

### APPENDIX E.

**Hypodermic Tablets, more especially for country use.**

### APPENDIX H.

**Inconsistencies in Dosage—**

Camphor, gr. i—x, yet spirit. camph. only m.x—xx.

Arsenic iod., gr. 1/8, yet liq. Donovani m. x—xx.

### APPENDIX I.

**Dosage to be given—**

Acotin. Apomorphine hydrochlor. Atropa sulph.

Hydarg. ox. rubr.

Iodum.

Phosphorus. Physoetigmine.

Potassa cyanid.

### APPENDIX K.

**Acacia mollissima (Will.), the common Victoria tan wattle,** and **Acacia decurrens (Will.), the Sydney tan wattle.**

Both contain 20, or greater, per cent. of tannic acid.

Decoct. acacie (formerly called decoct. mimose).

**Take of Acacia bark 1 oz., or 25 grammes; vase (distilled) 20 oz., or 500 C.C.** Boil for a quarter of an hour, allow to cool, strain through muslin, wash the contents of the strainer with distilled water until the filtrate measures 20 oz., or 500 C.C. The vessel in which the decoction is boiled should be of copper, glass, or glazed earthenware.

For the above identification the Committee is indebted to Baron von Mueller, and for the formule (which is the same as that in use in the Melbourne Hospital for the past 25 years) to Mr. C. R. Blacke, F.C.S., Government Analyst.
The work of the poor law infirmaries in our great cities is one that presents much of interest to the general public, and more especially, perhaps, to those who are actively engaged in the preparation and dispensing of medicines. A short review, therefore, of one of these institutions will furnish, I hope, some congenial reflections to our readers, and for this purpose we have selected one of the largest, newest, and therefore presumably best administered infirmaries of the metropolitan ashen, viz., Kensington.

The Kensington Infirmary is situated in a very extreme neighbourhood in Marlborough Road, and has the immense advantage of plenty of air space, while sitting at the same time centrally placed within the city. It has recently been enlarged at a cost of £60,000, and is now a very complete establishment. The wards of the new part are adorned on what is known as the pavilion system, ring separate buildings, but having an iron bridge connecting them, to be used in case of fire or other exigency requiring the transfer of the patients. Most of the most approved construction as regards ventilation, heating, and nursing requirements, and the general aspect strikes the visitor as one of great cheerfulness and cleanliness, so especially as some kind friends bring or send flowers, which are so great an adjunct to a sick man. Many medical and other professional men are inspected the buildings, and from all the most official approval has been received. One gentle, who had an ambulance and nursing class of as, asked permission to take the entire class in or that the members might have practical demonstration of the lessons they had received, and they were most favourably impressed with all the arrangements made for the comfort of patients. There is accommodation for about 600 inmates, who are under the care of three resident medical officers, under whom the matron, assistant matron, and about sixty nurses are engaged.

The dispensary is very complete and well fitted, and is larger than many a pharmacy; it is lofty, well lighted, warmed and ventilated; measures about 23 feet by 16 feet, and is 12 feet in height. Here the dispenser is hard at work all day, and frequently 150 bottles of medicine, etc., are dispensed daily by this gentleman, who appears to do the work easily and well without any assistant. From a return obtained, we note the following particulars:—During twelve months, 15 cwt. of lint, 9 cwt. of wool, 17 cwt. of tow were used; and of the chief drugs, cod liver oil, 50 galls.; olive oil, 45 galls.; linseed meal nearly 3 tons; quinine, 90 oz.; potassium bromide, 50 lbs.; potassa iodid., 20 lbs.; sodium salicylate, 45 lbs.; carbolic acid, pure, 350 lbs.; senega root, 1½ cwt.; confection of semens, 170 lbs.; and spirit of wine, 24 galls., were required.

The work of the dispensary may be divided into two parts:—

1. The making of various preparations according to the pharmacopoeia and private formulae. These include tinctures, infusions, ointments, compound powders, pills, syrups, and stock mixtures.

2. Dispensing the medicines for the infirmary workhouse, and out-patients.

The morning is devoted as much as possible to the former purpose, and the afternoon to the latter. The number of prescriptions dispensed annually is about 45,000, including infirmary, workhouse, and out-patients, giving a daily average of about 145, the lowest number in one day being 60 and the greatest number 275. This latter was during the epidemic of influenza.

The kitchen is on the ground floor of the administrative block in the centre of the building, and from this central hall everything not included under the term nursing is under the immediate control of the matron and officials. The fire hose, gas taps, and electric bells are all available in this department in case of need.

The infirmary is managed by a committee of fifteen members, including at present two ladies, two medical men (retired), and two chemists (one of whom is chairman), and therefore a very fair and wide experience of the knowledge required is obtained. Separate locked cupboards are kept in each ward for medicines to be taken internally, and poisons for external use, and every nurse
has the most stringent instructions to exercise great care in using them.

As showing the cost from a medical point of view in this institution, we find the expenditure is as follows:—

Average daily number of inmates under treatment, 463.

Cost of maintenance of inmates, £8637 per annum.

Cost of maintenance and salaries of officers, £6092 per annum.

Medicines and surgical appliances, £468 per annum, together with many incidental and minor amounts, such as for renewing furniture, bedding etc.
The medical officers receive salaries ranging from £400 with house to £80 per annum with board, lodging, etc., and the dispenser £140 per annum, outdoor. The most improved appliances are provided for the proper discharge of the duties of the medical staff. The operating theatre, lighted from the roof and with double doors to exclude cold or draughts, is equipped most admirably with everything experience can suggest for the purpose it is intended to fulfil.

A most useful feature of the infirmary is the training of nurses, and no less than thirty-seven probationers are here undergoing a course of three years' training. They are drawn from widely different ranks, and find, in nursing the sick, most congenial woman's work. They receive £12 per annum with board and lodging during training, and after passing the requisite examination, are eligible for the position of staff-nurse, and usually receive £25 to £30 per annum. They have a separate nurses' home apart from the infirmary building; sitting and dining rooms for their exclusive use are also provided.

Here is one field of work for women, not only quite unobjectionable in its character, but also most beneficent, which many are eagerly availing themselves of, and are finding a most desirable sphere of labour.

Hydraulic lifts are fitted to each floor, and a sub-way communicates with every part of the building; by this means the food is rapidly sent from the kitchen to each ward, thus keeping it hot, and therefore better relished by the patients.

Spacious outdoor airing courts and also a covered gallery are provided for those patients who are able to use them, and here one may see and experience the satisfaction that is felt by those who are soon to be again fit for work. The Medical Superintendent has authority also to recommend certain cases to be sent to convalescent homes at the seaside, and the guardians have several inmates in such institutions at the present time. Surely all this is good work undertaken by the ratepayers for those who are unable to provide for themselves, and on the whole we must come to the conclusion that the Kensington Infirmary is arranged and conducted on most humane and liberal ideas, and the guardians and parishioners may well feel proud of the work done by their infirmary.

DIPHTHERIA ANTITOXIN.

In a letter contributed to the Times and other papers on Wednesday last, Sir Joseph Lister, writing as Chairman of the Council of the British Institute of Preventive Medicine, states that a perfectly satisfactory diphtheria antitoxin has been prepared by the Institute, and that it is now proposed to produce it "on a very much larger scale, so as to be able to supply the great and ever-increasing demand of British practice." He also remarks that it appears to be a property of this antitoxin to confer temporary immunity with a single administration, the duration of the immunity being ample sufficient to protect attendants on diphtheria patients from an attack of the disease. It is reported by the Press Association that, as a result of the antitoxin treatment, a child under a year old, at St. Bartholomew's Hospital, has recovered from an acute attack of diphtheria. According to the published statement, tracheotomy had already been performed when the anti-diphtheritic serum was applied with successful results.

DISINFECTION IN HONG KONG.

In a report presented by Messrs. W. E. Cavendish Brown and Frank Browne, Government analysts, Hong Kong, the work of disinfection during the present epidemic is described. Experiments having been made in the Government Laboratory, selection was finally made of free chlorine, evolved from its combination with lime by means of diluted sulphuric acid, as the disinfecting agent. Half a pound of chlorinated lime was well mixed with a quart of water, in vessels placed in the centre of the infected room, and a quart of the diluted acid (1 in 5) added. For soldiers and thirty-six coolies carried out the work and the amount of chemicals used was chlorinated lime, 5100 lbs.; sulphuric acid, 575 lbs. These articles were manufactured in Java, whence they were imported, and are described as being of good quality, the chlorinated lime containing 34.7 per cent. of available chlorine, while two samples of the sulphuric acid contained 91.8 and 88.1 per cent. of real acid respectively.

COMMERCIAL COURT.

According to the Standard it is proposed, the suggestion of the Council of Judges, the Commercial Court should be established with mercantile cases exclusively. It will consist of three judges, including the Lord Chief Justice appointed by the judges of the Queen's Bench Division, and there will also be assessors and official referees to aid in the decision of technical complicated cases.

AWARD OF THE MOXON MEDAL.

On the occasion of the Harveian celebration of the Royal College of Physicians, the Moxon Medal for clinical research was presented to Sir William Jenner.
SIR HENRY ACLAND.

Under the head of University Intelligence the Times reports that Sir Henry Acland has tendered his resignation of the Regius Professorship of Medicine at the University of Oxford on the score of age and failing health. Sir Henry is now in his eightieth year, and this is the fiftieth year of his public work, having been during that period a member of the Royal Sanitary Commission and of the General Medical Council, besides occupying many other positions of distinction. The revival of scientific studies at Oxford has been in great measure due to the assistance rendered by Sir Henry Acland in the capacity of Lee's Reader in Anatomy and as Raddcliffe librarian.

ANTI-POISON STOPPER.

Another contrivance for the prevention of accidental poisoning has been provisionally protected by W. H. Hargrave, of 50, Sparkenhoe Street, Leicester, a working man. It consists of an "Anti-Poison Stopper" in the form of a spring attached to an ordinary cork, fitting any ordinary bottle. A circular plate of sheet steel is attached to a cork by a screw, and prolongations at two sides are bent downwards so as to catch under the lip of the bottle when in position. To remove the cork, the spring must first be forced open. It is further suggested that the word "Poison" in luminous letters should appear on the top of the spring, as well as on a label in front of the bottle.

INSTITUTE OF CHEMISTRY.

Among the successful candidates for the Associateship of the Institute of Chemistry at the examination held this month appear the names of Miss L. E. Boole, who has been for some time a student in the Research Laboratory of the Pharmaceutical Society, and Mr. F. H. Carr, the selected candidate for the Salters' Research Fellowship in Chemical Pharmacology, tenable at the same institution. Out of the seventeen candidates presenting themselves for examination thirteen were successful.

THE CHEMISTS' BALL.

As will be seen by reference to page vi. of our advertisement column, a meeting will be held at 17, Bloomsbury Square, on Monday next, November 8, at 2.15 p.m., for the purpose of making preliminary arrangements for the ensuing chemists' ball. Any gentleman willing to assist, but unable to be present at the meeting, will oblige by informing the Honorary Secretary, Mr. A. J. Phillips, 156, Cromwell Road, South Kensington, of his intention without delay.

FESTIVITIES AT MARGATE.

In the place of the usual mayoral banquet, the fayor and Mayoresse of Margate (Alderman and Mrs. E. S. Wootton) gave a ball on Thursday evening, October 26, at the Cliftonville Hotel. About two and a half hours were present, and the entertainment was of the most enjoyable character. Mr. Wootton was in business as a chemist and spirit merchant before August 1, 1898, and is the proprietor of one of the oldest pharmacies in Margate.

PHARMACOPEIA REVISION.

At page 357 will be found the full text of the report drawn up by the Victorian committee appointed to consider this subject and communicate with the General Medical Council. The previous reference to this report, taken from the British Medical Journal (see Pharm. Journ. ante, p. 266), was in some respects defective, but readers who are interested in the subject of pharmacopoeia revision will now be able to consider the suggestions made by the Committee, and we are much indebted to Mr. Shillinglaw for supplying a copy of the report.

IMPURE COMPRESSED OXYGEN.

Compressed oxygen is already apparently receiving attention at the hands of sophisticated, for a correspondent of Nature has recently tested two commercial samples and found them to be mixtures of 65 per cent. oxygen and 35 per cent. nitrogen.

EVENING MEETING IN LONDON.

The first evening meeting of the Pharmaceutical Society for the session 1894-95, will be held at 17, Bloomsbury Square, W.C., on Wednesday, November 14. On this occasion Professor Reynolds Green, M.A., Sc.D., has kindly undertaken to deliver a lecture on "The Nervous System in the Vegetable World," which will be illustrated by means of the oxyhydrogen lantern. The chair will be taken by the President at eight o'clock.

WESTERN CHEMISTS' ASSOCIATION.

The annual dinner of the members of this Association will be held at the Café Royal, Regent Street, W., on Wednesday, November 21, at 7 p.m., the chair being taken on the occasion by Mr. F. Andrews. Tickets, which are 6s. 6d. each, may be obtained of the honorary secretaries—Mr. Herbert Cracknell, 17, Craven Road, W., and Mr. A. J. Phillips, 156, Cromwell Road, S.W.

CHANGE OF ADDRESS.

The Apollinaris Company, Limited, desires to call attention to the fact that its address is now 4, Stratford Place, Oxford Street, W.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

The annual meeting of this Association was held on Friday, October 26, when a satisfactory report and financial statement were presented and adopted. Mr. Alderman Deck was elected president for the ensuing session; Messrs. A. Ivatt, M.A., and A. S. Campkin, vice-presidents; Mr. H. Cook, honorary treasurer; Messrs. C. S. Addison and H. R. Peck, hon. secretaries. And Messrs. Church, Greenwood, McAvoy, Parker, E. S. Peck, and Sturton, as other members of the committee. After Mr. A. S. Campkin had presented his report as delegate to the recent British Pharmaceutical Conference meeting, an inaugural address was delivered by Mr. Alderman Deck, who summarised the work of the past year, and congratulated the members on the prospects of the Association, whilst urging the younger members to take advantage of the opportunities afforded them in Cambridge of acquiring a scientific knowledge of their business.
Transactions of the Pharmaceutical Society of Great Britain.

FIRST EXAMINATION RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Wednesday, October 31st.

Certificates by approved examiners were received from the undermentioned in lieu of the Society’s examination:

Annesley, Sarah ......................... London.
Cuff, Sidney .......................... New Barnet.
Fuge, Dingley Palmer ................. London.
Hickman, Frederick Stanley ......... London.
Kemble, Luther ........................ Downham Market.
Westlake, Lionel Leopold .......... Windsor.

The report of the College of Preceptors on the examination held on October 9 was received.

Three hundred candidates had presented themselves for examination, of whom one hundred and fifty-nine had failed.

The following one hundred and forty-one passed, and the Registrar was authorised to place their names upon the Register of Apprentices or Students:

Abrey, Richard Blake Henry ... Battersea.
Adams, Robert Alexander ......... Glasgow.
Arnott, John Sinclair ............... Saltcoats.
Austin, Henry William .......... Nottingham.
Baldwin, F. E. Montague .. ... Greenwhich.
Ball, Joseph Eliajha .......... Mountsorrel.
Barnes, Henry ....................... Derby.
Batemon, Arthur Richard ...... Christohurgh.
Bathurst, Ernest Frank ......... Tewkesbury.
Boardman, Herbert ................. Leigh.
Boosey, William George ......... Manchester.
Boyd, John .......................... Annan.
Boardman, James Hector ......... Stockport.
Bradford, John Finnie .......... Liverpool.
Bramble, George Oliver ......... Burnham.
Buchan, Andrew ...................... Edinburgh.
Burchinshaw, Robert Llooy ... Colwyn Bay.
Campbell, Robert Spencer ....... Abbeystraw.
Cawley, George A. Leman .. .... Old Badford.
Chambers, Maxse William ....... New Watnall.
Clapp, Reginald John ............. Birmingham.
Clark, Alexander Robertson ... Brighton.
Clitheroe, Herbert George ...... Birmingham.
Cobham, Frederick Daniel ....... Carrington.
Cost, James ......................... Chichester.
Cooper, James ....................... Leicester.
Craft, Charles ....................... Reading.
Davies, Rowland Hughes ......... Ruthin.
Davis, Oliver Charles Minty ... Weston-super-Mare.
Dawson, Frederic William ...... Birmingham.
Donaldson, James ................. Newcastle-on-Tyne.
Eades, Joseph Edward ............. Tipton.
Early, Ernest Augustus ......... Walsoken.
Edwards, John ....................... Nottingham.
Edwards, William ................. Bridgend.
Ellis, Ellis William ............... Fochwen.
Evan, David ........................ Barry.
Evans, John ........................ Darwen.
Farquhar, James .................... Aberdeen.
Fern, Henry Arthur ............... Maconfield.
Foulds, Harry ....................... Stockport.
Fox, Thomas James ............... Portsmouth.
Fraser, John ......................... Dumfries.
Freeman, Thomas ................... Birmingham.
Gamles, Percy Horsey .......... Hartlepool.
Gelling, William Hiram ......... Douglas.
Glenie, George Ruddiman ......... Aberdeen.
Grant, William Low ............... Arbroath.
Groves, Thomas ..................... Long Eaton.
Hallgarth, Harold William ....... Thorna.
Hambly, Alfred Cornelius ....... London.
Hankinson, Herbert Stanley .. ... Liverpool.
Harries, William Edward ......... Kingston-upon-T.
Herschon, Daniel Robert ......... Bradford.
Hetherington, Vernon .......... Winchester.
Hodgson, John ...................... London.
Hughes, Arthur .................... Llanddoes.
Hutton, John ....................... Edinburgh.
Irvin, John Wallis ....... Hartlepool.
Iserlis, Isaac ....................... London.
Johnson, Geo, Gilbert Tudor .... London.
Kemp, John Wallace ............... Gosport.
Kershaw, Richard ................... Liddenden Foot.
Krause, Harry John Godfried ... Grimsby.
Lambirth, Henry Benjamin B.Winchester.
Langton William L ............... Leicester.
Layland, John ...................... Wighton.
Leek, Percy James .......... Uttoxeter.
Lewis, Moritz Avon .............. Pensance.
Low, John Grieve ................. Edinburgh.
Macartney, William .......... Belfast.
McDonald, John .................... Old Maldrum.
MacDonald, William .............. Inverness.
McDonell, Donald ............... Plymouth.
McGavin, William ............... Preston.
McLean, James ..................... Conon Bridge.
Macmillan, Kenneth J. C. ... Arbroath.
Martin, Wilfred ..................... Romford.
Miles, James Robertson ......... Dundee.
Monsman, John Raphael ......... Harrogate.
Moss, Bertie Victor .......... Coggeshall.
Nathan, Hyam ....................... Edinburgh.
Neal, Tom ........................... Leicester.
Newman, Reginald Travis ..... Haldleigh.
Nicholls, Katie Amelia ...... Hackney.
Oliver, Ada Kate ................. Plymouth.
Park, James ......................... Denholm.
Peacock, Frederick .......... Darlington.
Pearse, Frederick ................. Dulwich.
Penney, Harry Clayton ......... Chichester.
Powell, Bertram Henry ......... Sutton Coldfield.
Pratt, Inley Leveque .......... Paddington.
Price, Evan ....................... Rhayader.
Puddeshat, Isaac James ....... Coventry.
Read, Robert ....................... Thorne.
Rhead, Alfred ............... Milton.
Richards, Frank R. G. ....... Maconfield.
Ridgley, James H. .......... Harrow.
Ridgway, James Herbert ....... Patriofoft.
Roberts, John ....................... Bangor.
Robson, William Taylor ....... Berwick-on-Tweed.
Rogers, Ernest ................. Wolverhampton.
Sear, Leonard ...................... Houghton.
Scott, Charles Edward ......... York.
Selby, Horace Walter ......... Sevenoaks.
Shorrock, Mary ................. Darwen.
Shrive, William Ernest ....... Cambridge.
Simpson, George ................. Dufftown.
Smithies, William Oscar Ball .... Birmingham.
Snome, Alfred ...................... Plymouth.
Smalley, Robert ................. Preston.
Smedley, George Roger ....... Barrow-in-Furness.
Smith, Daniel ....................... Nairn.
Smith, May .......................... Norwich.
Smith, Percy Lewis .......... Hanley.
Smith, John Henry ........ Hartlepool.
Smith, William ............ Newcastle-on-Tyne.
Solomon, William Denton ....... Birkenhead.
Starky, Tom ......................... London.
Stephenson, John Gathorne B.Manchester.
Tew, Frederick Arthur ....... Saltford.
Thomson, William .......... Inverarity.
CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting of this Association held on Thursday, October 29, the President, Mr. R. H. Jones, in the chair, a paper of which the following is an abstract, was read:

CHEMICAL AND PHARMACEUTICAL SIGNS AND SYMBOLS.

BY T. Tickle.

The mystic symbols which adorn the show bottles of pharmacies perhaps help to impress the pharmacist's customers with the depth of mystery there is in his art. Formerly they constituted a system of shorthand and secret writing, for the substance with which the apothecary or alchemist dealt. As far as can be shown, they were arbitrarily chosen for the greater part. Everyone invented symbols for his own use, and the result followed that the symbols employed by different men varied very greatly. No less than seven different symbols for lead have been handed down to us; and not only can no one of them be put down as a modification of another, but no two of them appear to have any connection.

The seven common metals were supposed to be connected in some mysterious way with the seven gods or heavenly bodies. The metals known to man also, of course, applied to each heavenly body as its appropriate metal. The metals were apportioned to the deified heavenly bodies as follows:—Gold, the Sun; silver, the Moon; quicksilver, Mercury; copper, Venus; tin, Jupiter; iron, Mars; lead, Saturn.

Rockwell, in his interesting book, "The Birth of Chemistry," says:—"It is difficult to say how the symbols conferred upon the planets and afterwards upon the metals arose. They are undoubtedly of Chaldean origin, but to what extent they have since been modified no one can tell."

Dr. Percival, in his "Selecta a Prescriptis," gives a very credible and interesting idea of the origin of some of the symbols. He derives them all from the symbol of gold and the Greek cross which he takes to represent acrimony, the word acrimony meaning the substance of corrosive property which, combined with gold in different proportions, produced the various other metals. The crescent, he says, indicates the property of being half gold, for one side is like the symbol for gold while the other is the same reversed; that is, if you turn the inner part of the crescent outwards you have the symbol for gold. Copper has the sign of gold on the top, because of its colour, and the sign of acrimony beneath. The brass symbol with a crescent of acrimony, as well as the symbol from that of silver on the top from its colour, that of acrimony beneath, and that of gold between, for, like all the metals, gold was supposed to lurk in it combined with acrimony. Iron was supposed to contain acrimony of a different nature from that of the other metals, being represented in this symbol by the barbed spear-head.

Certain symbols seem to be closely associated with the doctrine of Aristotle, who taught that the four so-called elements—fire, air, water, earth—each had two qualities, one of which was common to some other element. Thus he said: Fire is hot and dry, air is hot and moist, water is cold and moist, earth is cold and dry. The properties making up fire and water were directly opposed to each other, and so were those of air and earth.

He pushed the connection still further, and said if the dry of fire be overcome by the moist of water, air be produced, if the moist of water be overcome by the cold of earth, water will result. The idea expressed in this is in accordance with that which has lurked in the minds of philosophers for a long time, namely, that all matter is evolved from one substance.
A discussion followed the reading of the paper, in which the Chairman and Messrs. Moore, Robins, Sage, Plant and Morley took part. Mr. Tickle having replied, had a vote of thanks accorded him. The proceedings then terminated.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

A special meeting of the Chemists of Nottingham and district, convened by the Nottingham and Notts Chemists' Association was held at the Eagle Restaurant, Nottingham, on the evening of October 26, when, in response to an invitation from the local executive, Mr. R. D. Gibbs (President of the Midland Pharmaceutical Association) and Mr. H. Kamp (President of the Federation of Local Chemists' Associations) read papers which raised an interesting discussion. The chair was occupied by the President, Mr. R. Fitzhugh, J.P., and in spite of the inclement weather there was a fairly large gathering.

Before the proceedings commenced, the following new members were admitted—Messrs. Gassolynes, Abbott, Wildsgrove, Sinclair, Cook, Geidlothorpe (Nottingham), Greaves (Ironville), Adams (Manafield), and Potts (Ilkeston).

The Chairman, having briefly opened the meeting, called upon Mr. R. D. Gibbs to read the following paper:

Hindrances to Success.

BY R. DARTON GIBBS.

I propose to take up a short period of time with you this evening and discuss some difficulties that preclude our maintaining our position. Although the title suggests a great deal I shall limit myself as much as possible, because it is more important to emphasize a few points than mystify you with many. In dealing with some obstacles on the road to success I must point out that if you want to find them you will have to have a close look at them because we all have a way of setting ourselves down and making no effort will never know, and will probably never care, what the obstacles are. That individual will not have taken the trouble to come here to-night, and therefore I may safely assume I am addressing myself to a number of earnest men who desire to display all those characteristics which are to be found associated with success.

I would bid you notice that in these local associations the most prominent men, the men who give time and work and money to make them a success, are those who have had the larger share of success in their own work, men who know what the hindrances are, and who show an anxiety to clear them away, so that pharmacy may not be stagnant, but show the same signs of progress which are to be found in other departments of human activity. Gentlemen, there are some special difficulties that arise from some what complicated position, and in my address at the opening meeting of the Midland Association I found it necessary to trace the lines we had followed in order that we might be quite clear as to where we were. I showed that our existence was brought about by a set of circumstances that would now be considered abnormal, and that we are liable to changes that may threaten that existence which was called into being by the wants of the physicians embodied into a society with the druggists, by the activity of the Society of Apothecaries, and that, strengthened and solidified by education, we became what we are, submitting ourselves to examination as a voluntary act, and attaching ourselves to a society whose interests were our interests, the body of that union it was not our interest to treat. Such was our position prior to 1868. It may help you to understand this position better if I refer to a society whose relations with the public correspond very closely with ours, the Institute of Chartered Accountants. Of both auditors and pharmacists it is said they should show proof of technical skill, and that the public should have some guarantee of those upon whose skill they are relying are qualified and honest. Now in 1880 the Institute obtained its charter just as we did eighteen years ago, and if we must submit you to a voluntary examination over which the Institute has absolute control, and prove your capacity as an accountant, you must continue to subscribe to its rule by year by year, and expect to have your name struck off its rolls if you find yourself guilty of unprofessional conduct. The accountancy does not seek the examination it is satisfied with any requirement of law, but in order that it may be received into a society, may be a member of that society, be supported by the society, and gain the distinction of being a chartered accountant, the moment he separates himself from that society he loses all these advantages. To find the Institute is powerful because united and powerful because held together by the powerful inducements. Well, gentlemen, this is our position once; it is not so to-day. As an unfortunate moment we accepted the responsibilities and expenses of an Act of Parliament, what we asked for, but which Parliament granted, and this has proved indirectly the greatest hindrance to our advancement. You may cast some doubt on the correctness of my views, but I would ask you to study the development and progress of pharma
cacy from 1842 till 1868—sixteen years—and the twenty-five years which have since passed, and I have no doubt in my mind that you will recognize the exact cause be what it may, that the Act did not bring unexpected blessings to pharmacy or phar
macists which were looked for, and that I shall be right in directing your attention to this Act for solution of the difficulty.

Now, I have pointed out the condition of pharma
cacy under an incorporated society depending on membership. The examination was of secondary im
portance—that is to say, it was the river you swam across to get into the promised land. The association of members and interest in the work, and friends and interest in the work, and friends and interest in the work was the test of whether it was your interest to stay. It was equally your interest to remove those who would not conform to the well-being of the whole. Have we institu
ted for this? A society that is so far independent of you that it can afford to say we are not dependent on membership, we can get our advancement in other directions, and so if membership ceased it would effect us only in degree.

Is that a society calculated to be of use to you at show signs of progress? When a society ceases to be dependent on membership, members may not pay their subscription fee. And how does this work out in practice? Why, four-fifths of the examined men find it cheaper to look on from the outside, leaving only their friends to subscribe to its funds. Now you are from time to time, when, if you will stop outside, are the stumbling block to our progressiveness, it does anyone, after twenty-six years of experience, and after ten years of the Act, after twenty years of results, seriously think the time will come under the present rule when the whole of men will be persuaded that membership of the Pharmaceutical Society will prove their salvation? Is too great an effort of the imagination has brought about this change? Was it that the Act? Gentlemen, I want you to think the right
at yourselves. I do not want to do other than trust your minds generally; it is together we must work if we are really anxious to be of help. I have sketched what the 1868 Act destroyed. What is it to give us in return? A register, not of chemists, not of pharmacists, but of apothecaries. It placed the examination as the aim and object of every pharmaceutical aspirant, instead of he Society. This was quickly discarded, and cramming schools were soon established for manufacturing pharmacists on the "payment on result" system. Then you got a poisons' schedule, and the privilege of selling those very seldom called for articles to the public in small quantities; but if a man wants, say, a pound of cyanide of potassium, anyone may do it on the plea of a wholesale transaction. This poison arrangement was not passed in recognition of our increased abilities, but distinctly in the o-called interest of the public, which needed protection twenty-six years ago, when the world had a poisoning epidemic. You cannot attach much value to the result for what you lost. Now what have we got beside? Are you the producers of pharmaceutical preparations as you might be? Are you responsible men have it. Should we be the isolated beings, each struggling for existence, depending on a society which has become valueless because State-ridden? Suppose the plumbers form themselves into a society, and submit themselves to a proof of their skill, and then are able to call themselves registered plumbers. It may be of great value to a man, and also the public, because it distinguishes him as a man upon whom you can rely, and in so doing gives him an advantage over the not qualified and unaccredited man; but suppose this society has no control over him, has not the public lost the virtue of its guarantee? and if he was fixed, not the Society of Plumbers, whose interest it would be to maintain its worth, but by a State department, would not the blue still further decrease? And then you have only the qualification of the standard until every man with a blue could do the work, the lazy to scrumble. So long as apathy reigns, so long will there be no signs of progress. Why are pharmacists apathetic? Is it the smell of the drugs that procures this effect? Is it that he thinks the State must at time regain consciousness of its injustice and rant us some relief, or is it the condition by long hours of labour, by living to ourselves, moderating our wants, and being content to struggle on from day to day waiting for some to turn up? Whatever it is we must seek a remedy. Doctors deal with these cases by advising long holiday, by urging you out of yourself by useful and learned and unqualified? Surely if pharmacy is to be worth anything it can only be by each adding something new to the world's store of utilities. There is as large a field of usefulness associated with the calling of the pharmacist as is to be found in any other department of human activity, but it is the activity that is wanted. This activity should show itself in an individual educating process, that constant seeking after information and usefulness, that coming up to date process which is as necessary with us as with other departments of life, and nothing is so likely to help forward this work as a strong association working together with these aims. Gentlemen, I must thank you for allowing me to take up so much time, and to express my desire for your individual and collective welfare, and to hope these meetings will help to bring the results we are hoping for—a brighter day for pharmacy and pharmacists.

The following paper was next read:

LOCAL ASSOCIATIONS AND THEIR FEDERATION.

BY H. KEMP.

It is not my intention to traverse the ground covered by Mr. Gibbs, and it would be improper for me to criticise either his facts or his arguments. I am, however, bound to say I do not agree with some of his
contentions, and I fail to see that a compulsory examination is in any way responsible for the unsatisfactory condition of things during the period of twenty-six years which has elapsed since the passing of the Act of 1868. I must leave it to you to discuss the points which he has raised, confining myself to the consideration of local associations and their federation.

The fact that I have for some time past taken an interest in local pharmaceutical associations, and have been placed in a prominent position in the large company, the whole trade, for you, my friends, to understand the value of the latter, I feel justified in saying that greater interest is taken in former by a large majority of the members. I am somewhat this to you—to let others than myself and my trade a fore of the associations you have, and where none exist, of others. To those who are members I say, "start your local associations"; and to those who are not, let me urge you to take an interest in this work. The point a moral as well as to adorn my tale, I say all, "Don't forget the associations whose role lies in trade topics."

As any movement which is, in even a small degree calculated to increase the interest taken in local national pharmaceutical affairs, or to enhance the efficiency of your councils must certainly be a body has to-day, or no other, whether you give as reasons for believing that a federation of local associations will go far to meet a long-felt want in the directions.

Has it never occurred to you who are members of your deliberations, no matter how wisely you act and your decisions, be they ever so fateful, rendered futile in most instances by reason of the fact that you are such a small, very small, part of the trade that you are unable to exert any real influence on one way or another outside your own immediate set. It must have thus presented itself to your minds and again. Then, after deploring the fact, you have wondered whether any good to yourselves or to pharmacists in general could come out of your consultations and discussions, and whether after all they were not a waste of time. At the same time, has it not occurred to you that if you were in touch with several other parts of Great Britain, some good might have resulted from your consultations. Of course your mind has dwelt upon this possibility too.

A few months since, we were entertained for a while by a deputation corresponding to the trade journals upon the merits or otherwise of a Pharmacy Bill. I do not go so far as to say that no good comes of this kind of discussion, but maintain that it is impossible for an opinion of any value to be formed from it to the effect that the present legislation has on the great body of pharmacists. Small a matter as it first seemed, I should like to have had it under discussion by chemists in every district throughout the country, and, if approved, resolved in support of it sent to the Pharmaceutical Council. Actions of this kind would materially strengthen the hands of the Council, but without any one directing body such things are impracticable, and I have heard that the same man has many admirers or few. Yet what an important matter it is! Aiming, as it does, at consolidation concerns every man who can call himself chemist. It may be urged that this principle could be carried too far, and every action of the Council be subjected to criticism. I would anticipate this, and give it my opinion that the Council has nothing to fear, honest criticism, and that no man worthy of the name, who holds a representative position, will shrink from a discussion of his policy. Besides, we would afford such a splendid opportunity for removal of current misconceptions, and where against least supine neutrality towards the Pharmaceutical Society. I am prepared to admit that discussion policy might lead to a consideration of the subject.
a representative, but this would be a distinct
disadvantage. The facetious editor, who last April paid
the compliment of a special leader by poking fun, and
turns his attention to a difficulty we labour under, a
benefit to be derived by our having an opportunity of
exerting any organised effort to secure the return of the best men to the Council.

I must all be ready to pay our tribute of admiration
for the self-sacrificing work done on our behalf by
the members of that Council; it would be most ungenerous
to do so, and I am very apprehensive of scaring my
readers into the opinion that we never had a more energetic
Sympathetic Council than we have at the present
moment. Still, it would be mere affectation to say that
no one among them could be replaced with advantage,
it would be absurd to think that a self-sacrificing man with "an
as to grind" might not obtain a seat on the Council.

Yet, no matter how much you in Nottingham or
in Manchester may be convinced of the unsuitability
of a given candidate for the office he seeks we can do
nothing little to hinder his election.

And my colleagues believe that a federation will
solve these difficulties, and enable local associations to
meet in any ways. Rules are being drawn up, but until we
settle the definite line on which the Federation shall
be formed, it would be improper for me to say that
will or will not be attempted or done. But I may
say in my ownpdf opinion upon one or two points, and,
take the last first, I think a small executive chosen
from the different associations might reasonably
be asked to make a recommendation to those associa-
tions upon the election of the Pharmaceutical Council.

This, too, that same executive might, on its own
responsibility or at the suggestion of any federated
association, call upon different districts to take into
consideration at the earliest possible moment any
motion of policy which might be of an urgent

Mr. A. E. Bellamy, in opening the discussion, said that
the members of the Nottingham and Notts Chemists' Association had devoted most of their time to
educating their apprentices and students. With regard
to trade matters, they had shown the blankest indiffer-
ence, and they ought to be grateful to Messrs. Gibbes
and Kemp for having come to stir them up to some kind
of interest in their material welfare. He took it that
the main cause of their want of success lay in the ex-
reme competition of modern times, a competition not
obscured by the rivalry of companies that had been
able to start in opposition to them by what was a mere
law in the framing of the Pharmacy Act—but also of
every kind of shopkeeper. In addition to this
unfair competition, they had little opportunity of dis-
ensing doctors' prescriptions. These were very
serious hindrances. He desired them to be overcome.

Somewhat to his surprise, Mr. Gibbs took up the posi-
tion that if they could only return to the state of
things prior to the passing of the Pharmacy Act, a
much better condition would prevail. Were they
to return to the condition of things prior to the Act
competition, in his opinion, would be very much greater.

The Act was a great and a powerful boon. It had
weeded out incompetent men, and he contended
that they ought to be grateful for that Act, inasmuch as it had given a better education to chemists,
and had given them a position through registration.
The chemist was a recognised individual, and in many cases a great and powerful position in his trade.
The Act in other respects had been a
distinct advantage to the trade, and what they required
was to be more State-ripped. A chemist was expected
to perform certain duties, and in return he should have
certain privileges. With regard to the sale of poisons, he thought chemists ought to be protected,
not only should the sale of poisons be restricted to
chemists, but all galenical preparations of the Phar-
macopoeia. If they would only make an effort in this

would probably lead to an extension of the established
association as well as to the formation of new ones.

I am fully aware that we had an annual
meeting in London, where the Council is sometimes
convened and questions of policy discussed. But the
out going so far as to say that it is often uninteresting
and unprofitable, I may venture to suggest that it is
not popular with the provincial pharmacist. At all
events, the gentlemen who usually attend are almost
exclusively drawn from the metropolis and its suburbs.

This little change, year by year—in striking contrast to the B.P.C.

At present there is no organisation for bringing
London and provincial men together in the provinces
for discussion of those topics which, as I said before,
occupy quite as much of our attention as the technical
ones. It has been considered quite impracticable for
the Pharmaceutical Society to hold an annual meeting
of this kind in the provinces: there, it seems,
isperable obstacles in the way, and as the B.P.C.
does not countenance pharmaceutical politics we must
have a meeting quite distinct, and the Federation
wants to arrange for it.

Now, gentlemen, I think I have talked enough for
to-night, and, although I may not have enlightened
you much or told you anything that is new, I hope I
have provided some of you with matter for thought.
You in Nottingham have exhibited commendable
aptitude in taking up this question, and I feel per-

sued that in your representative, Mr. Bollan, we
have a colleague possessed of both tact and energy—
talents which are much required in putting a scheme
of this kind on a permanent and business-like basis.
I am glad to see you are making a special effort to
extend your membership, and I wish you abundant
success.
direction, he felt sure that, in spite of the free trade
proclivities of the times, they would finally succeed.
They had to look after their material interests, and
in his opinion, their best interests could only be
served by a more close connection with the State
through the Pharmacetical Council. With Mr. Kemps
address he was in thorough sympathy. The
individual chemist was practically powerless, and it
was only by collective action that he could make him-
self felt in the country. In addition to the local
associations, he did think they ought to support the
Pharmaceutical Council, though they did not get a
strong Pharmacy Bill in the first instance arose from
the fact that so few members of the trade were
connected with the Pharmaceutical Society. If chemo-
ists would only join, they would give a democratic
character to that Society, and its representations
would then come with greater force to the Govern-
ment.

Mr. W. H. Parker, who followed, said that his advice
to the trade from the first had been that the members of it
ought to join the Pharmaceutical Society, and mould
its Council as they wanted it. The difficulty, however,
argued with regard to membership. He had been the
local secretary for many years, and he had been con-
tinually asked by chemists how they could be made
members. The fact was that they could not be made
members until they had passed the Major examination
and become pharmaceutical chemists. They did
not seem to take the title of associate, though it practi-
cally admitted them to membership. Federation,
in his opinion, was the only remedy for bringing pressure
to bear, and he did not know any better scheme than
that brought forward by Mr. Kemp.

Mr. A. Middleton said he supported Mr. Bellby's
contention as to the advantages gained by the passing
of the Pharmacy Act. He wished to express his high
appreciation of the scheme Mr. Kemp had
foreshadowed. There were something like 15,000
chemists in the country, and if they could only get
a petition signed by 15,000 chemists he was sure they
would be heard upon their grievances. Other organisa-
tions of far less standing had accomplished all they
desired by this means. But the simple case was that the
Society, which was the recognised authority, was so
do badly supported that its voice was practically
unheard. He would just as soon be called an associate
as a member. He felt sure that the one title on the
stamp board or on a label would carry as much weight with
the public as the other.

Mr. W. Gill (Secretary) observed that they had to
take facts as they were, not as they used to be. They
had a society brought into existence by the passing
of the Pharmacy Act, and they must recognise Society.
He thought that to give their best support to the
Society in London was the only way in which they
could achieve what they wanted. He heartily
agreed with Mr. Kemp's views on federation, and he
would like to see the local associations not only in
touch with the Federation, but with the Society in
London. Unless they combined they really could do
nothing.

Mr. C. A. Bolton (Vice-President) said that the
reason chemists were worse off than formerly was
because of their apathy. How could they get the
members of the trade to take an interest in their
own material welfare? Even the match girls and the
clerks did that, but they could not get chemists to look at things in the same way. The man who stood outside the Pharmaceutical Society was a dead weight preventing them obtaining those
privileges which were their right. He hoped that
each member present would feel that the success of the
Federation depended upon himself. The difficulties of
obtaining legislative enactment had been referred to,
but these things would never come until they were
united and they had said to the Pharmaceutical
Society, "We have made our minds up on this
and are going to work for it."

Mr. Gibbs first replied. He said that the action
of the Pharmaceutical Council with regard to the mix-
poisons clearly showed that the days of close trade
were over, and the sooner they recognised it and
worked on some workable ground the better. The
result of the discussion all seemed to tend in
the same direction, and the only answer he had got
was practically what Mr. Bolton had said, that
the Society was now going in those
years ago. That being so, they had better accept
the fact.

Mr. Kemp also spoke very briefly, stating that
there was nothing to reply to.

The meeting closed with votes of thanks to
the speakers and the chairman.

LEEDS CHEMISTS' ASSOCIATION.

The annual general meeting of the above Asso-
ciation was held in the Library, Leeds, on 18th
October 26, Mr. R. Reynolds (President) in
the chair, Mr. W. D. Pollitt (Honorary Secretary) read
the following annual report:—"The Council, in pres-
enting the twenty-sixth annual report, records the
death of an old member, Mr. T. Be-
chcliffe.

"The library has been maintained in a condition
of efficiency, small additions having been made
during the year, and more use has been made of
books and materia medica specimens by
association. "Your Council thinks that the Association has
just claim for support from the members of the trade
and, amongst other reasons for that claim, we refer to the present state of pharmaceutical law.
It is highly desirable that associations such as the
should maintain their organisation, so as to be
ready at any time to support the Pharmaceutical Society's endeavours to enforce the principles of the Phar-
acy Act of 1888, especially with regard to the
retailing of preparations containing soothing
poisons."

The financial statement showed a balance in hand
of £2 9s. 10d.

Votes of thanks were accorded to the Council
of the Pharmaceutical Society for the gift of the Phar-
acy Journal, and to the Executive Committee of the
British Pharmaceutical Conference for the gift of the "B
Book" for 1893.

A cordial vote of thanks was given to Mr. S. J.
lor, who had resigned the office of treasurer to
past services.

The following officers and Committee were also
to continue for the coming year:—President: Mr. Richard Reynolds.
Vice-President: Mr. E. Yewdall.
Hon. Treasurer: Mr. P. Jefferson.
Hon. Secretary: Mr. W. D. Pollitt.
Committee: Messrs. F. W. Branson, G. B.
Auditor: Mr. E. Brown.

LIVERPOOL CHEMISTS' ASSOCIATION.
A meeting of the members of this Association was
held on October 25, at the Royal Institution, Le-
quint Street, Mr. M. Conroy presiding. Several
points were discussed. Mr. W. Parkinson, Local Secretary of the Phar-
caceutical Society, was resigning that position, as
he had held for a long period. Mr. J. Smith,
elected president of the Association for the se-
ing session, and afterwards a paper on "pre-
the British Pharmacopoeia" was
read by Mr. R. U. Cowley.
Scottish Transactions.

1ST ABERDEENSHIRE CHEMISTS' ASSOCIATION.

The annual meeting of the East Aberdeen chemists' Association was held at Maud on Oct. 25. Mr. George Whyte, Fraserburgh, occupied the chair. A resolution was moved and seconded from Mr. McGregor, Elgin, the president, regretting an unavoidable absence. Mr. Tocher, the secretary, read the presidential retiring address, which dealt with the current topics in pharmacy. On a motion of the chairman, the secretary was instructed to convey the hearty thanks of the meeting to the president. A discussion took place on the Pharmacy Act, and several proposed amendments which have been brought forward from time to time. Mr. John Johnston, Aberdeen, member of the Pharmaceutical Council, was present by invitation, and gave an account of the pharmacy bill and its effects upon chemists and druggists. A discussion took place, in which Mr. Cruickshank, and Mr. Robertson, Fraserburgh; Mr. Walker, Elgin; and Mr. John, Peterhead, took part. On the motion of Mr. Robertson, a vote of thanks was heartily corded to Mr. Johnston for coming so far to present at the meeting. Mr. John Wilson, Dunblane, New Rochelle, New York, a native of East Fife, was also present by invitation, and gave an account of the pharmacy regulations in the United States of America, which was much appreciated.

J. G. Grant, Methick, was elected president for the ensuing year, and Mr. Tocher, Peterhead, as reappointed secretary.

Parliamentary and Law Proceedings.

PROCEEDINGS IN THE COURT OF CHANCERY.

MANDALL'S PATENT FOR LICORICE.

The petition of the Pharmaceutical Society of East Fife for the renewal of this patent was in a paper for hearing before Mr. Justice Chitty on Tuesday, October 27, but on it being stated that it was opposed, and that oral evidence would be required, a lordship directed that it should be put in the list cases to be heard with witnesses. The hearing was therefore deferred. The patent (No. 6178 of 1893) is for a medicine (licorice) for the cure of coughs, colds, soreness, and bronchitis, which is composed of a decoction of liquorice root, Irish moss mucilage, gum arabic mucilage, glycyr sine, chloroform and morphine in the form of chloroform, syrup of squills, syrup of aniseed, squills, wasabi, pippins, and rhubarb, and benzol acid.

POISONING CASES AND INQUESTS.

CARDIOIC ACID CASES.

Elizabeth Lee, aged 45, of Beswick Street, Salford, died on Tuesday, October 23, from the effects of taking carbolic acid. Verdict: "Suicide."—Manchester Courier.

Hannah Jenkins, aged 38, of 12, Laxey Street, Liver-

poisoning cases and inquests.

Alfred Ernest Sinclair, aged 15, of Great Jackson Stweet, West Gorton, died on Sunday, October 28, after drinking carbolic acid and falling into a cellar. Verdict: "Died from dislocation of the spine and carbolic acid poisoning."—Manchester Courier.

DEATH FROM OVERDOSE OF ARSENIC.

William Horton, aged 31, commercial traveller, of Aston, Birmingham, died at Cardiff on Saturday, October 27, from the effects of an overdose of arsenic, alleged to have been taken to induce sleep (sic.) Verdict: "Died from arsenic poisoning."—Western Mail.

Dispensing Memoranda.

[653.] In the following prescription the bismuth sometimes cakes at the bottom of the bottle:

- B. Bism. Subnit. \( 3\) 5m
- L. Calcs. ad \( 3\) vill.
- M. ft. mist.

It has not been determined whether this is caused by the bismuth being excessively acid or the lime water weak, either or both producing a slightly acid menstrum; or the bismuth normal, that is, slightly acid, and the lime water full strength, thus forming an alkaline supernatant liquid. It would be interesting to know what takes place.

[654.] B. Oceain. Hydrochlor. \( 80\) grains.
- Vaseil. Adi. 1 ounce.
- Pt. Unguentum.

The medical man wishes the salt to be used. Is it preferable to add oleic acid or not, and what is the solubility of oceain. hydrochlor. in oesin. ald.?

W. F. G.

[655.] Can you give me any information as to how the following prescription for pills may be best dispensed:

- B. Terebinth. Venet. 3.
- Ezt. Hyoscyam. \( 3\) 3m.
- Pulv. Rhei. \( 3\) 3m.
- Camphor. \( 5\) x

M. et divide in pil xxv.

Sig. One or three times a day.

Correspondence.

LEONurus Cardiaca.

Sir—This plant is noted by Babington, rare—Johns and Miss Pratt assigning it for respectively only two localities. For the first time in my experience I found it growing on a piece of waste ground that a few days afterwards was dug over as an allotment—planting it in a border it flourished remarkably well. Miss Pratt quotes an "old herbalist" who extols its virtues as superior to any other remedy, and having the power to cause a merrie heart." The origin of the name seems obscure. The flowers grow in crowded whorls, and before their expansion suggest "aphides," in some country places of Kent termed "another." Is it probable that the rustic etymology may have been "another-wort?" Dr. Turton, M.D., in his medical glossary, gives "Leonurus, λεονερος, from λεος, a lion, and αρις, a tail—"i.e., "naming from its likeness"—rather fanciful, it must be admitted. Anyhow, the therapeutic value of the herb is generally acknowledged, and Mr. Holmes has done good service to medicine in digging it out. Personally, I feel obliged to him for, being possessed (con-
Genitality of a heart that has pursed all the doctors—"Yes, instinct, intuition, pulse, ought to give up business, etc.," I naturally feel interested in any proper remedy. Having given the infusion of motherwort a trial, I can confidently state it possesses tonic properties are superior to the numerous drugs hitherto prescribed. A trust in Holmes may be. The satisfaction of introducing a humble 'indigen' to its true position as an ameliorator of human suffering, thus illustrating the text of a writer in the Apocrypha, "The Lord has been in the wilderness, to see his people." Is wise will not eschew them.

Kingston-on-Thames. R. GODWIN MUMBLAY.

Weights and Measures.
Sir,—Will you permit me to remark, touching Mr. Dott's interesting paper on "Weights and Measures," that he falls into the curious though popular error of assuming (gratuitously) that decimalis object to fractional divisions. There is no more objection to the gramme being divided into halves, quarters, or any other fraction considered convenient than there is to dividing the grain, although practically it is found more convenient to use the decimal point. Think that "long-winded vocabulary. Well, I think even there, although a minor point, that gramme and litre are at any rate as musical and easy as any hundred-weight, quarter, kilderkin, pondeer, hogshead, let alone adopting the "pawh" of Devonshire. Even the cubic centimetre when written c.c. or c.cm. and vocally abbreviated into C.c. (se-se) is not unwieldy. Curiously enough Mr. Dott used an argument generally claimed by decimalists, that is that 38ks. 12dr. 6grms. 3d. is more simple than 329 grms., but it would be equally relevant to ask which is easier to remember, 18.3 Grms. or 8 dr. 1 scr. 3½ gr., which is putting it very moderately. When we compare the multiplication of such amounts as 1 lb. 16 oz. 4 dr. 2 scr. by 17½ 4d., with 118¼ x 17¼, we are struck with the immense superiority of a system which does away with one swoop with compound arithmetic. There is no reason why our own system of weights, measures, or coinage should not be used after being decimalized the committee found it preferable. I think, too, the danger of missing the decimal point is overstated. I have seen more mistakes made by confusing the 9 and 5 signs than with the decimal point, beside which a man who could deliberately mistake 01 Grms. of strychnine for ten times that quantity ought not to be trusted to calculate T or T½ of a grain. I have in my own and other pharmacies for several years used for all purposes, except buying and selling, weights between the number of parts, thus 20, 50, 100, 120, 150, 250, 500, and 1000, and all entries in our prescription books are made in terms of grains and minims when the quantities are under 1 oz. Not only do they make it very easy but, in all cases, very easy to calculate. The fact is we have come to look on our old system of weights and measures as a sort of "Divine ordinance," but it is not that. It is an inexorable jumble of incompatibles, and I do not believe that a gentleman of Mr. Dott's intelligence honestly thinks it is the "perfect system" he says it is. We have only to remark how portions of this perfect system are becoming obsolete (e.g., the 9) to see that it is nothing but a question of time, and that English people will eventually follow the example set by every civilized country in the world by adopting a decimal system.

Member of the Decimal Association.

Sale of Proprietary Medicines.
Sir,—In your Journal for October 26, Mr. Visser wrote on poisonous proprietary medicines with a reference to Powell's balsam of aniseed. I have examined half-a-dozen bottles in stock of this proprietary, and find that three bottles have a small printed label pasted on to the wrapper with the word, "Warning, as made since 1824, contains, amongst other valuable pectoral ingredients, a very minute and harmless quantity of opium; and, therefore, to meet the requirements of the Act of Parliament, it is necessary, etc." The other three bottles have no label indicating their poisonous nature. This may be owing to an omission on the maker's part, or to the wholesale house having procured a stock of the balsam before the maker began to affix the printed slip. I would recommend that the declaration as to the poisonous ingredient be printed as part of the wording on the wrapper, as done by the makers of Dr. Collis Brown's chlorodyne. The printed slip on Powell's balsam could very easily removed, and then no clue would be given to its poisonous composition. I am at once with Mr. Visser that the makers of proprietary medicines should be enabled to distinctly label any nostrum containing poisonous or deleterious ingredients in accordance with the Pharmacy Act. I remonstrated with wholesale dealers placing a distinguishing mark in their price lists against proprietary medicines containing poisons to a certain extent, and I hope it will be adopted by Messrs. May, Broad. They insert in itals below each poisonous proprietary the words "saleable in the United Kingdom by qualified chemists only." This is a plan which can be imitated to advantage by other wholesale suppliers. "Caledonia."

THE CHEMISTRY OF IPECAUANHA.

BY DR. B. H. PAUL AND A. J. COWNLEY.

Since the publication of our last paper on this subject we have endeavoured to prepare larger quantities of the salts of the two bases we then described, and in the course of our experiments have been struck with the comparative facility with which the emetine hydrochloride crystallises in the presence of an excess of acid. Upon adding moderately strong hydrochloric acid to emetine it is immediately converted into a bulky mass of fine silky crystals, whereas the formation of crystals from a neutral aqueous solution of the salt does not take place until after some considerable length of time, and the solution has become very concentrated. This difference of behaviour suggested the possibility that an acid salt was formed, but on analysis of the silky mass of crystals that was not found to be the case. Considerable difficulty was experienced in obtaining the salt in a state fit for analysis, on account of the large quantity of mother liquor retained by the crystals. Drying by heat gave a salt that was neutral, containing 12-83 per cent. HCl as previously stated.†

On pressing the spongy mass of crystals between the thumb and index fingers the material thus imperfectly dried gave the following results on analysis: —

<table>
<thead>
<tr>
<th>Found</th>
<th>Calculated for</th>
</tr>
</thead>
<tbody>
<tr>
<td>C₂₂H₂₂N₂O₅·HCl·H₂O</td>
<td>C₂₂H₂₂N₂O₅·HCl·H₂O</td>
</tr>
<tr>
<td>Emetine</td>
<td>67-68</td>
</tr>
<tr>
<td>HCl</td>
<td>10-78</td>
</tr>
<tr>
<td>Water (by difference)</td>
<td>19-59</td>
</tr>
<tr>
<td><strong>100</strong></td>
<td><strong>100</strong></td>
</tr>
</tbody>
</table>

It appears evident from these results that no acid salt is formed, though the presence of free acid promotes the crystallisation of the neutral salt. The amount of hydrochloric acid in a dry acid salt having the composition C₂₂H₂₂N₂O₅·2HCl would be 22.74 per cent.

Cephaline behaves in a somewhat similar manner. A neutral solution of the hydrochloric acid dries up over sulphuric acid to a varnish-like residue without any sign of crystallisation. But when the solution contains excess of acid, fine, transparent rhombic crystals are formed. In this case also the salt formed is not an acid salt, as seemed to be probable. When dried over sulphuric acid it gave the following results on analysis: —

**Cephaline Hydrochloride Crystallised from Solution containing excess of Hydrochloric Acid.**

<table>
<thead>
<tr>
<th>Calculated for</th>
<th>Found. C₂₂₂H₂₂N₂O₅·HCl·H₂O·aq</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cephaline</td>

<td>HCl</td>
<td>11·2</td>
</tr>
<tr>
<td>Water (by difference)</td>
<td>16·8</td>
</tr>
<tr>
<td><strong>100</strong></td>
<td><strong>100</strong></td>
</tr>
</tbody>
</table>

A dry acid salt having a composition corresponding to the formula C₂₂₃H₂₂N₂O₅·2HCl would contain 23.96 per cent. of hydrochloric acid.

Indications of this remarkable tendency to crystallise in the presence of excess of acid have previously been observed in the investigation of the ipecacuanha alkaloid by Dumas and other chemists.

* See ante, p. 111.
† Ibid., p. 114.

The current number of the *Archiv der Pharmacie* contains a communication from Dr. Kunz-Krause of Lausanne, in reference to the papers published in this journal on the alkaloids of ipecacuanha. Dr. Kunz-Krause lays claim to priority in the publication of a description of the basic constituent of that drug, and of various conclusions as to its molecular formula, etc. The chief details of the results arrived at by Dr. Kunz-Krause in his investigation were stated in the following propositions, which appear at the end of the paper published by him in 1887:†

I. That emetine has the molecular formula C₂₂H₂₂N₂O₅, and yields a platinum salt, having the composition

C₂₂H₂₂N₂O₅·2HCl·PtCl₄.

II. That it is consequently a bi-acid base like quinina.

III. That it is a diamine (tertiary), since it yields, after addition of methyl, an ammonium base, methyl-emetonium hydrate:

C₂₂H₂₂(CH₃)₂N₂O₅·OH.

IV. That emetine is very probably, like quinina, a derivative of chimoline.

These propositions are now republished by Dr. Kunz-Krause, supplemented by some others relating to the constitution of emetine, and they are referred to by him as representing the existing state of knowledge of this subject, for the elucidation of which Dr. Kunz-Krause claims priority. That claim, however, is at once superfluous and inadmissible, for the data we have given as the result of our observations upon the physical characters, composition and salts of ipecacuanha bases are totally incompatible with those given by Dr. Kunz-Krause, and the previous publication of his paper was duly acknowledged by us. It is not therefore a question of priority, but one of reality which has to be considered.

In the description of the results obtained in our study of ipecacuanha we furnished evidence of the existence of at least two distinct bases in that drug, the difference between them being marked by their physical characters, by their composition, and by their salts. This difference is especially indicated by one of the bases being crystallisable and freely soluble in caustic alkali, while the other one is uncrystallisable and insoluble in caustic alkali.

Those observations were recorded with a full knowledge of the conclusions at which Dr. Kunz-Krause had arrived in 1887: they did not raise any question as to the prior publication of his paper on the subject, and though they were of a nature to throw doubt upon his conclusions as to the individual nature and constitution of the base which he had described under the name of emetine, their publication is not, as he suggests, an "unjustifiable criticism" of his previous work. The reasons for the doubt as to the nature of the base are distinctly stated at the end of our last paper, and may be here briefly recapitulated.

The paper published by Dr. Kunz-Krause in 1887 contains internal evidence that the basic product obtained by him from ipecacuanha, and named emetine, was not a chemically individual substance, but an indefinite mixture of two or more of the

* Pharm. Journ., iii. 61, and liv., 111.
† Archiv. der Pharm., [3], xxv., 461.
different bases which we have described. Thus, for instance, the sparing solubility of the substance in cold ether, its melting point, its capability of crystallising, and its comparatively considerable solubility in hot petroleum spirit, and even in water,† as well as its partial solubility in caustic potash‡ are characters which do not belong to the base isolated by Glénard and described by him under the name of emetine, or to the amorphous base of corresponding composition which we obtained. These are characters which approximate to, though they are not exactly the same as, those of the other base we have isolated and named cephaline.

The uncrystallisable base identical with that described as emetine by Glénard, is soluble in ether, but insoluble in caustic alkali, and very sparingly soluble in water. It is also very sparingly soluble in petroleum spirit, even with the aid of heat, and owing to its low melting point it readily aggregates into a mass, which is then so little acted upon by the solvent as to be almost insoluble.

Bearing that circumstance in mind, it is obvious that the process by which Dr. Kunz-Krause prepared the substance he described as emetine, viz., by boiling petroleum spirit, was just of such a nature as to give a mixture consisting chiefly of cephaline with a small proportion of true emetine, and presenting characters belonging partly to one base and partly to the other. Analytical data relating to such an indefinitely mixed substance are necessarily of little value, however numerous they may be. Consequently the conclusions arrived at by Dr. Kunz-Krause as to the composition and constitution of emetine are wanting in foundation adequate for the purpose, and for that reason we abstained from entering upon a premature discussion of the views expressed by him as to the constitution of emetine, confining ourselves to a bare statement of the results of experiment.

The paper which has just been published by Dr. Kunz-Krause in the Archiv contains much that is irrelevant to the main issue above stated, and the settlement of that issue would only be obscured by entering into a discussion of these subordinate points. It may, however, be useful to give a comparative statement of the figures by which the percentage composition of the substances in question have been expressed.

We hope shortly to be able to publish further descriptions of the salts of these bases, together with an account of their physiological action.

‡ A solution containing only 1/4 of the hydrochloride becomes turbid on addition of a drop of caustic soda solution.

THE TRINIDAD ASPHALTE INDUSTRY.

The famous pitch lake near the village of La Brea, in Trinidad, is probably the largest deposit of asphalt in the world. It occupies what is thought to be the crater of a mud volcano, and has an area of over 100 acres. Its depth is unknown, but borings have been made which show that at least in some places it is over 200 feet. The surface is, as a whole, so firm that it can be walked over with ease, though the rivulets and pools of water which are scattered over it at times impede progress. At one or two points, however, soft pitch is still welling up, accompanied with the evolution of sulphuretted hydrogen gas, and here a man sinks up to his knees in a very few minutes. Even the apparently solid asphalt is quite viscous, and hence the general level of the lake is slowly sinking as digging goes on. The movements taking place in the mass are illustrated by the fact that a couple of islands which were considered to be stationary have lately been discovered to be gradually moving. Besides the pitch lake there are in Trinidad some other asphalt deposits, which are, however, of no great importance. They consist of pockets of pitch, which are found in the land surrounding the lake. Whether they are the results of the overflowing of the lake at some former time, or whether they are of independent origin is a point which does not appear to be definitely settled, but it is pretty well agreed that the asphalt obtained from them is not the same as that from the lake. Physically it is less tough and viscous, while chemically it contains a smaller percentage of bitumen. Of late very little, if any, has been exported. The reason for this is partly, no doubt, its recognised inferiority for industrial uses, but more especially the fact that the concessionnaires have acquired all the ground in which land pitch exists with the exception of a little in the village of La Brea and some Crown land. From the latter, under the terms of the agreement, pitch may not be exported.

The Trinidad traffic in asphalt has only become important within comparatively recent times. Twenty-five years ago the total export was under 6000 tons. In 1892 it had risen to nearly five times that quantity, while in 1892 it exceeded 100,000 tons. pitch. The appliances for transporting the asphalt from the lake to the sea—a distance of about a mile and a half—have recently been greatly improved. Formerly it was conveyed in mule carts, and the arrangements for shipment were somewhat clumsy. Now there is an overland tramway running down from the lake to the end of a long pier, where the material is tipped directly into the boats. By the time it reaches the end of its voyage it has run into a homogeneous mass, and has to be dug out in much the same way as it was originally from the lake.

The development of this asphalt trade is of considerable importance to the colony of Trinidad, seeing that the Government receives a royalty of 6s. 8d. on every ton exported. The income thus obtained is more than sufficient to pay the interest on the public debt, and has the additional advantage of costing very little to collect. The concessionnaires deposit
$10,000 with the Government at the beginning of the year, and pay royalties on the quantity exported over and above the 30,000 tons covered by the deposit.—

Times.

THE PREPARATION OF COCAINE.

The complete separation of cocaine from the accompanying alkaloids found in the leaves is a troublesome and tedious operation, and has been superseded to a large extent by methods based on our knowledge of the constitution of these alkaloids.

It has been shown that the chief alkaloids found in the leaves are cocaine (methylbenzoylcochine), isostryptol-cocaine, and cinnamyl-cocaine, and they may thus be considered as built up from methyl-ecgonine by combination with different acid radicals.

"The principle of the process employed" consists in the decomposition of the accompanying alkaloids by acids, the formation of ecgonine by splitting off the different acid radicals as methyl esters, and the subsequent partial synthesis of cocaine from the ecgonine thus obtained.

The method employed is as follows:—The leaves are extracted by a suitable solvent, and the greater part of the cocaine is removed by fractional crystallisation. The alkaloidal residue, containing a little cocaine, is then decomposed by boiling with strong hydrochloric acid into ecgonine and the methyl esters of the different organic acids. Finally, the ecgonine is separated and purified, and then converted into cocaine. Two methods can be employed for this conversion: (1) The ecgonine is first benzoylated and then methylated by treatment with methyl iodide and soda, or, better, by passing dry hydrochloric acid gas into a solution of benzoylcochine in methyl alcohol (Einhorn); or (2) the methyl ester of ecgonine is first formed, and then benzoylated to form cocaine. In both cases we require to add the two groups, and for this two operations are necessary.

Einhorn has devised a method (Bericht, xxvii., 1523) which necessitates only one of these synthetic operations, and this depends on the fact above stated, that the different alkaloids may be viewed as consisting of methyl-ecgonine combined with different acid radicals, and instead of decomposing the total alkaloid into ecgonine, the methyl ester of ecgonine is obtained, which then only requires benzoylating to yield the required alkaloid. The method is as follows:—50 grammes of the accompanying alkaloids are boiled with 300 grammes of methyl alcohol and 100 grammes of pure sulphuric acid for 3 to 4 hours in a water-bath. The alcohol is then distilled off and the syrupy residue treated with a little water in which the methyl-ecgonine is dissolved, and the greater part of the organic acids precipitated as methyl esters. The aqueous solution is now extracted with chloroform, and then made alkaline with excess of potassium carbonate, when the ecgonine methyl ester separates as an oil, which is then easily extracted by chloroform.

A modification of this method consists in passing dry hydrochloric acid gas into a methyl alcohol solution of the accompanying alkaloids, and, after cooling, heating for two hours. The methylyecgonine is separated by the same method as used when sulphuric acid is employed.

The yield is found to be theoretical, and the resulting methylyecgonine was recognised as such by purification and the identity of the melting point of its hydrochloride with that previously recorded. It can be distilled with very little decomposition in a vacuum.

When the methyl alcohol is replaced by ethyl alcohol, the higher homologue of cocaine is obtained, and we have thus a simple method at command for forming any of the higher homologues by dissolving cocaine in the required alcohol, and saturating with dry hydrochloric acid gas and boiling for two hours.

The process above described depends on a very general method of preparation in organic chemistry, viz., the formation of a methyl ester by treatment with methyl alcohol in presence of sulphuric or hydrochloric acid. In this case the ecgonine is produced under conditions that at once induce the formation of methyl ecgonine, which then only requires benzoylating to yield cocaine.

CANADIAN BALSAM FIR.

While there has been little or no increase in the consumption of Canada balsam fir within the past five years, the supply has been gradually diminishing partly as a result of natural conditions, and partly because the work of gathering has been, to an extent, neglected. The collection of balsam fir is not a regular industry, but has been prosecuted by lumbermen and labourers in other fields, who devoted their leisure to it. So long as the balsam could be obtained near by the markets to which the gatherers bring it the supply was ample and regular, but with the cutting down of the Canadian forests for timber the source of supply has been further and further removed from commercial centres, and the collection of the balsam has not proved profitable enough, for a number of years past, to encourage those who heretofore engaged in it to continue to bring it to market.

In some years the supply has been larger than in others owing to the scarcity of other employment, and in view of the widespread distress among the labouring classes, including the Canadian lumbermen, during the past eighteen months or more, it would be natural to expect that these people would have turned their attention to the gathering of balsam as a means of livelihood. Such, however, does not appear to have been the case, for according to reliable reports the quantity collected this year was very small, not exceeding fifty barrels. This small yield was partly due to wet weather toward the end of the gathering season—late August and early September—but the chief reason for it is that the gatherers found it unprofitable to go so far into the interior for the balsam as they are now compelled to go.—Drug Reporter.
PROTEID POISONS.*

Proteid poisons have been obtained from both the vegetable and animal kingdoms. Thus among those obtained from plants, one may mention the proteids obtained from jujwity seeds, the proteid associated with or identical with the ferment papain of the papaw plant, and lupino-toxin from the yellow lupin.

The most important of the animal proteid poisons are snake poison; the proteids in the serum of the conger eel and other fish; and proteid' poisons found in certain spiders. Poisonous proteids are also formed during ordinary digestive processes in the alimentary canal of every one of us from the proteids taken in as food. The peptones and the proteoses or albumoses (intermediate products in the process of hydration of which the terminal product is peptone) are fairly powerful poisons. 0.3 gramme per kilogramme of body weight injected into the blood will kill a dog, producing a loss of coagulability of the blood, a fall of blood pressure, a stoppage of secretions, and ultimately death by cessation of respiratory activity. Normally, animals are protected from this poison by the lining membrane of the alimentary canal, so that no proteose or peptone is found in blood or lymph even during the most active periods of digestion. The cells of this membrane possess many remarkable properties, but one of the most important is this power of regenerating albumin from peptone.

Allied to the albumoses of ordinary gastric activity are the similar products produced by bacteria. The way in which bacteria produce disease has long been a matter of dispute, but the problem appears to be approaching solution. Pathologists have at last turned their attention to the chemical side of the question, and shown that whereas in some cases the poisons produced by the growth of micro-organisms are alkaloidal in nature, in far the greater number the toxic product is a proteid. The one which is best known, or at least attracted most attention, is the tozalalbumose contained in Koch's tuberculin.

The foregoing list is far from complete, but one cannot conclude it without mentioning another class of proteid poisons: these are the nucleo-albumins obtainable by suitable methods from most of the cellular organs of the body. Originally discovered by Woollridge, they were named by him tissue-fibringens, because they possess the remarkable power of producing coagulation of the blood within the blood vessels of a living animal. A very small dose will kill a rabbit or a dog, and death is as a rule produced by extensive clotting within the vessels, especially in the veins. Under certain conditions, however, especially in the dog, they produce the opposite result, namely, a loss of coagulability similar to that produced by peptone. Woollridge termed this the "negative phase of coagulation."

A practical outcome of all this work is the discovery of alyxes or protective proteids. These appear to belong to the nucleo-albumin class also. In small doses they confer immunity on animals to larger doses of similar poisons, and thus the long-hidden secrets of the modus operandi of vaccination and other forms of protective inoculation is at last beginning to be unravelled.

A NEW MICROSCOPICAL LABORATORY.

The opening of the new Microscopical Laboratory of the Philadelphia College of Pharmacy marks an epoch in the history of that institution. It means that, hereafter, practical work in the microscopical laboratory will be required in the same measure as practical work in the pharmaceutical and chemical laboratories.

The laboratory is situated on the fourth floor of the College buildings, facing east, and is about forty-five feet square. It is flooded on three sides with light from large windows, and the walls are painted a delicate buff tint.

The room is provided with ten tables, each accommodating ten students, so that one hundred students can be instructed at one time. It can be lighted by electricity, there being four lights to each table. So, if night-work becomes essential, ample light is assured. There are four hundred drawers for holding students' supplies, each of which is provided with a number-combination lock, for which, of course, no key is required.

The surface of each table has been treated with boiling paraffin, making it impervious to corrosive reagents. Lengthwise along the centre of the table is a line of twelve reagent bottles for each student, partially sunk in the counter, and each bottle is provided with a separate glass rod, so that the mixing of reagents is avoided.

For the use of the juniors, one hundred simple microscopes are on hand; for the seniors, there are one hundred compound microscopes. They are of the most approved pattern. A closet is provided for each when not in use. Wall-cases with tin canisters have been set up in which to keep material for work.

On the west side of the room, in the centre, is the lecturer's desk, with a large blackboard for demonstrations in the rear. Alongside is a lead-covered table for the preparation of reagents, maceration of vegetable tissues, etc., with a fume-hood to remove any noxious gases which may be generated.

Each junior student will have one exercise a week through the term, in the study of roots, stems, leaves, flowers, etc., and in the study of crude vegetable drugs.

Each senior student will have one exercise a week with the compound microscope, in studying the structure of plants and crude drugs. Special courses for advanced students will be added as the demand for them arises, and as time permits.

The courses are open to all students of botany, whether students in pharmacy or not. The charge is the same to both, namely, $15 for each course. A deposit to cover breakage is required of each student in the junior course, amounting to 75 cents, and in the senior course to $2.50.—Alumni Report.

Deductions to the Chemistry of Cerium.

By W. M. Dennis and W. H. Magie.

(Continued from page 340).

II. Qualitative Tests for Cerium.

Early in the work the necessity arose for testing various solutions and residues for the presence of traces of cerium, and a comparison of the different methods which have been proposed was made to ascertain which test was most distinctive and delicate.

Until 1884, when Gibb5 proposed his lead dioxide test for ceria, no satisfactory method for the qualitative detection of this earth was known. In 1882 Hartley6 proposed a more delicate and also a more easily applied test, using ammonium acetate and hydrogen peroxide. In 1883 Leconq de Boisbaudran,7 and also Cleve,8 observed that hydrogen peroxide gave to solutions of cerium salts, to which an excess of ammonium hydroxide had been added, a precipitate of the same colour as that yielded by Hartley’s reagent; namely, an orange-red. Sonnenschein,9 in 1870, had proposed the use of ceria as a test for strychnine, and Plugg6,10 in 1881, has reversed this, using strychnine as a test for ceria. Finally, Gibb11 in 1894, has proposed to substitute bismuth tetroxide for lead dioxide in his test.

Hartley appears to have been the only observer previous to Plugg to test the delicacy of the reactions proposed. He found that if a quantity of a cerium salt, equivalent to one Mgm. of the element, were dissolved in 100 C.C. of water, the addition of ammonium acetate and hydrogen peroxide gave a distinctly brown or orange-red precipitate which could be filtered off, dried, ignited, and weighed. “Hence we can separate one part of cerium from 100,000 parts of liquid.”

To test the delicacy of these various reactions one-half gramme of ceric oxide was dissolved, as sulphate, in a litre of water. Each cubic centimetre of this solution would contain one-half Mgm. of ceric oxide.

When one C.C. of this solution was diluted to 100 C.C., ad five C.C. of the diluted solution was boiled with excess of lead dioxide and nitric acid (1:2), a faint yellow tint was to be observed, but four C.C. failed to yield a distinguishable colour; that is, 0.025 Mgm. can be detected in about seven or eight C.C. The bismuth tetroxide detected 0.017 Mgm. under the same conditions.

In testing Hartley’s reaction, one C.C. containing one-half Mgm. was diluted to 100 C.C., each cubic centimetre then containing 0.005 Mgm. of ceria.

When two C.C. of this solution was diluted so much that with the solution of ammonium acetate and hydrogen peroxide it formed about four C.C., a yellow colour was visible, especially on looking downward into the test-tube held above a white surface; 0.01 Mgm. of ceric oxide, or rather the cerium salt equivalent to this, can, therefore, be detected. Ammonium hydroxide and hydrogen peroxide gave as distinct a colour with one C.C., that is, Boisbaudran’s test is twice as delicate as Hartley’s.

Next, Plugg’s strychnine test was tried and proved to be as delicate as he claims. The strychnine solution is prepared by dissolving one part of strychnine in one thousand parts of sulphuric acid. The solution suspected of containing ceria, or a few cubic centimetres of it, is rendered alkaline by sodium hydroxide, evaporated to dryness, and a drop of the strychnine solution is added. One-tenth of a milligramme of ceria gives a distinct blue or violet colour, changing to red. One hundredth of a milligramme gives a faint blue tinge which rapidly fades. If oxalic acid be present it must be decomposed or the test fails. Boisbaudran’s test is then the most delicate of any yet proposed.

Finally, known amounts of lanthanum and didymia (mixed) and ceria in solution were mixed and Boisbaudran’s test applied. A distinct coloration of the hydroxides was produced when 0.01 Mgm. of ceria was mixed with 0.1 grammes of lanthanum and didymia in about 100 C.C. of solution.

To apply the test in the presence of a large excess of other rare earths, very dilute ammonium hydroxide solution should be employed, and this added drop by drop until the first permanent hydroxide remains after shaking. The hydrogen peroxide is then to be added—only a couple of drops are needed—and the mixture well shaken. By this means the weakly basic ceria is precipitated almost alone, and the orange-red colour cannot be disguised.

III. Cerium Chloride.

The ceric oxide, prepared according to the directions given in the first section, was purified from any thorium present by boiling the oxalate (prepared from the sulphate) with a concentrated solution of ammonium oxalate. Any thorium oxalate dissolved, was poured off and a similar solution poured over the residual cerous oxalate. The whole was then boiled and allowed to stand for some months with occasional shaking. The mixture was then brought to boiling and the liquid again poured off, the residual oxalate being washed with a similar solution. This washed oxalate was then dissolved in nitric acid, care being taken to ensure full decomposition, and it was then almost neutralised with ammonium hydroxide. Potassium hydronitride was then added so long as it continued to throw down a precipitate. This was filtered off, leaving a solution of cerium nitrate containing only potassium and ammonium salts, with possibly traces of calcium. This solution was precipitated with ammonium hydroxide and washed by decantation until a litre of the wash-water left no residue on evaporation. The ceric hydroxide was then tested for calcium, potassium, etc., with the spectroscope, and proved to be free from all foreign material. This pure hydroxide has been employed to prepare salts of cerium.

As this work has been in reality only preliminary to an extended study of cerium, many of the already known salts were prepared in order to become familiar with their characteristics, but of these there is no need to speak at length.

A salt, which may probably be rightly claimed to be a new compound, was prepared while endeavouring to obtain cerium tetrachloride. This latter should be capable of existence if cerium is properly placed in the periodic system. Every other element in group IV of that system forms such a chloride, not even excepting lead.* Among other attempts made, one was as follows: A concentrated solution of ceric chloride, obtained by dissolving ceric chloride in hydrochloric acid and evaporating, was placed in a wash-bottle surrounded by a freezing mixture (snow and salt), and dry chlorine gas run in. This was rapidly absorbed, and after a short time a white crystalline mass settled out. This was placed on a porous porcelain plate to remove the greater part of the liquid, and then the following experiments were tried with different portions:

An attempt was at first made to dry it to constant weight over dry caustic potash in vacuo. A large, but irregular, loss of weight occurred and the crystals evidently effloresced. On exposing it to the open air again it gained in weight till almost as heavy as at first.

* An attempt to dry it over calcium chloride gave a similar result. A portion was then dried in air, dust being excluded.

Weight of sample taken after 72 hours 2.9624
118 2.9790
142 2.9786
166 2.9786

The chloride therefore assumes a constant weight in air.

In analysing this air-dried chloride the cerium was first precipitated from the aqueous solution of the salt by ammonium hydroxide. The precipitate was so gelatinous that it was difficult to wash it free from chlorides, and the oxide obtained by ignition of the precipitate was not of a pure yellow colour. The percentages of cerium obtained in two analyses were 38.01 and 38.19.

In two other samples the cerium was thrown down by ammonium hydroxide and hydrogen peroxide was added. The orange-coloured hydroxide thus formed was not as gelatinous as that formed with ammonia alone, and was much more easily washed, but on ignition of the precipitate the resulting ceric oxide was of a pale pink colour. This colour may have been due to the presence of a small amount of a higher oxide, for the results—38.01 and 37.93 per cent. cerium—while not agreeing as well as could be wished, were too high (see analysis below). The chloride was determined by precipitation as silver chloride, and the water by the method suggested by Kraut.†

The above analysis showed that the compound formed by passing chlorine into a cold saturated solution of cerous chloride was merely a fine crystalline form of ceric chloride, and not a ceric chloride. Inasmuch then as the formation of the compound was probably due not to the oxidising action of the chlorine, but to its dehydrating power, it seemed reasonable to expect that dry hydrochloric acid gas would accomplish the same result. The hydrochloric acid gas was made by the action of concentrated sulphuric acid upon solid ammonium chloride; the apparatus of Norblad being used for this purpose. Upon passing the gas into a cold concentrated solution of ceros chloride, the same white finely crystalline compound separated as with the chloride. This was dried in the air to constant weight and then analysed. In determining the cerium, the orange-coloured hydroxide was precipitated by ammonium hydroxide and hydrogen peroxide but, after filtering, the solution was heated just to boiling. The suspended hydroxide changed to a bright yellow colour, but did not become gelatinous, and was easily washed. On ignition it yielded a ceric oxide of the usual pale yellow colour.

The fine crystalline form of the chloride was kindly determined by Mr. A. S. Eakte, of the Geological Department of the University, who states that the ceric chloride is orthorhombic in crystallisation.

The above chloride seems to be distinct from that obtained by Jolin* and by Lange,† for which the formula 2CeOCl₃.15H₂O is generally given.‡ The chloride may be made by dissolving ceric hydroxide in hydrochloric acid, and evaporating the water-bath until the solution becomes quite viscous. This solution placed in a desiccator while hot solidifies on cooling to a crystalline mass of a yellow colour. If these crystals be allowed to stand in the air they lose their colour and a glassy coating appears to form over the surface. The differences between the results obtained by Jolin and by Lange, and the variation of each of the analyses from the calculated percentages, made it seem desirable to repeat the analysis of chloride prepared by Jolin's method to see if better results could not be obtained. A sample of their chloride was therefore prepared by us and analysed; and the results showed as great a variation from the theory as those already mentioned.

The Pharmacetical Journal

FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, NOVEMBER 10, 1894.

NOTICE TO MEMBERS, ASSOCIATES, AND STUDENTS.

Communications for the Editorial department of the journal, books for review, &c., must be addressed to the Editor, 17, Bloomsbury Square, London, W.C.

INFORMATION DEPARTMENT.

Advertisements and remittances must be sent to Street Brothers, 5, Serle Street, Lincoln’s Inn, London, W.C., where copies of the Journal may be purchased. Cheques and money orders must be made payable to “Street Brothers.”

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Brengridge, 17, Bloomsbury Square, London, W.C.

THE COUNCIL MEETING.

The business transacted by the Council at the meeting last Wednesday was for the most part of a routine nature. The reports of the several committees did not raise any questions for discussion, and were unanimously adopted.

In connection with matters of finance the President mentioned that though the balance in hand on the credit of the Benevolent Fund, amounting to £547, might seem large, there will be heavy calls in January, for meeting which more will be required.

On the recommendation of the Benevolent Fund committee, one grant of twenty pounds, one of thirteen pounds, and three grants of ten pounds each were ordered to be paid.

In connection with the annuities the Treasurer expressed regret that the number of annuities to be elected in December could not be extended from four to seven. The Vice-President, in reply, said that this feeling of regret was shared by the Committee, but under existing circumstances it did not feel justified in putting extra burdens upon the Fund.

In reference to the recent death of Mr. Edward Horner, it was resolved, on the motion of the President, that a letter of condolence should be sent to his widow on behalf of the Council. Besides occupying a prominent position in the wholesale trade and in other capacities in the city, Mr. Horner was one of the founders of the Society, and for some years acted as one of the auditors. Old readers will remember that Mr. Horner was present at the jubilee dinner of the Society in 1890, and was on that occasion the last surviving founder.

The omission to refer to his death at the last meeting of Council was due to some uncertainty as to whether the announcement which appeared in the papers related to the old friend and founder of the Society.

After the formal appointment of local secretaries for the ensuing year, it was resolved that superintendents of written examinations should be appointed at the same centres as last year, and that these appointments should be offered to the local secretaries at those centres. The appointment of assistant local secretaries was deferred until next month, until the names of those chosen by the local secretaries had, as their assistants, been submitted to the Council for approval.

A report was presented stating the centres at which Preliminary examinations have been held during the past year, with the number of candidates at each, and it was ordered to be entered upon the minutes (see page 386).

A resolution was passed that the meetings of the Boards of Examiners, in 1895 and 1896, should take place in January, April, July, and October.

At the suggestion of the founder of the Manchester Scholarship, and on the recommendation of the General Purposes Committee, it was resolved that the first three books of Caesar’s Commentaries shall be added to the subjects for examination for this scholarship, as an alternative to the first three books of the Aeneid.

In reference to the opening of the new premises in Edinburgh on the 30th inst., it was resolved that a conversation is to be held at the Society’s house in Edinburgh on that occasion, and that the Executive of the North British Branch be authorised to take the requisite steps by issuing invitations in the name of the President, Vice-President, and Council of the Society.

The resolution adopted by the Chemists’ Assistants’ Association as to the provision of a course of post graduate lectures and laboratory demonstrations during the coming winter and submitted to the Council was referred to the Library, etc., Committee for consideration.

The portion of the General Purposes Committee relating to legal proceedings stated that many penalties had been paid without trial, some judgments have been obtained, and other cases are awaiting trial. Proceedings were ordered to be taken in several other cases which have been reported to the Committee.

EVENING MEETING IN LONDON.

Professor Reynolds Green, M.A., Sc.D., will give an illustrated lecture on “The Nervous System in the Vegetable World” at the evening meeting of the Pharmaceutical Society on Wednesday next, November 14. The President, Mr. Michael Cartwright, will take the chair at eight o'clock prompt.
PREVENTIVE MEDICINE.

The diphtheria antitoxin is still on its trial, but the trial has been adjourned sine die by the failure of the supply of material. The public are thus left with breathing-time in which they may inform themselves of the nature and scope of the latest project of scientific medicine, and pharmacists are given leisure in which they may learn the mode of preparation of the new claimant to a place in the materia medica. The public are almost as cautious as the scientists in forming their opinions in the present instance. Pity it was not the same in the case of the potent, but, alas! not remedial tuberculin!

After the bacillus of diphtheria was first discovered by Löeffler much circumscpection was displayed before it was admitted to be the cause of the disease. It was found to be constantly present on the surface, that is in the oldest parts, of diphtheritic membrane. Later, Roux and Yersin found that certain animals when inoculated with pure cultures of the bacillus contracted an affection presenting all the peculiarities of diphtheria in man: false membranes, intense inflammation, and in many cases the peculiar diphtheritic paralysis. Thus the micro-organism satisfies all Koch's postulates, and must be regarded as the causa vera of the disease. The bacillus is always accompanied by multitudes of streptococcii, which, by the toxins they produce, doubtless assist in producing the phenomena of the disease. The next step in the evolution of the antitoxin was a discovery made by Roux and Yersin. These observers found that old and strongly alkaline cultures of the bacilli in broth, freed from the micro-organisms by filtration, possessed highly poisonous characters. The filtrate when injected beneath the skin of guinea-pigs, pigeons, etc., caused intense inflammation and diphtheritic paralysis. Such filtrates evaporated in vacuo at a temperature of 40° C. to one-third of their bulk, and dropped into absolute alcohol acidified with acetic acid, yield a flaky grey precipitate which is readily soluble in water, and can be purified by re-precipitation and dialysis. Thus is obtained a white powder which gives the chief reactions of an albumin and possesses the same poisonous properties as the original filtrate. The purified product is thus a typical "toxalbumin."

In 1889 Roux, speaking to the Royal Society, was able to formulate a further advance in knowledge, thus:—"The immunity which we could only give by the introduction of a living virus we can now effect by the introduction of a chemical substance into the tissues, and these vaccine substances are exactly those which have been observed in infectious diseases as being the cause of death. In large quantities they kill, in small they confer immunity." The next important step towards the present position was made by Behring and Kitasato, who found, in 1890, that the blood of animals which had been rendered refractory to tetanus by the method just referred to was capable of destroying the poison of tetanus both in test-tubes and after injection in rabbits and mice suffering from the disease. This important property of the blood of animals rendered proof against tetanus was found to hold good of many other affections, including diphtheria, and even for snake-poison. It is not known how the serum acts on the toxalbumin of diphtheria, but it is surmised that a substance is formed by the cells of the immunised animal which is capable of destroying the poison. This substance is the "antitoxin." Whether the antitoxin acts directly by a chemical reaction, or indirectly through the cells of the body is not settled definitely. But the latter hypothesis is the more probable, since the amount of antitoxin required to immunise animals of different species varies even when the animals are of the same weight. This hypothesis has also the support of an observation made by F. Klemperer, who found that the yolk of the egg of an immunised hen was anti-toxic, whilst the white of the same egg was not. We have in a former article (October 13, 1894) sketched the mode of preparation of the antitoxin serum, and are glad to know that a fresh supply is being prepared at the Institute of Preventive Medicine in London. This will enable full statistics to be provided on which a final judgment may be pronounced. For the purpose of statistics it will be better to exclude all cases except those in which the bacillus of diphtheria has been found by cultivation.

THE NEW JOURNALISM.

In the Journal for October 13 last an article, "Higher Education for the Pharmacist," by Professor John M. Francis, was reprinted from the Pacific Druggist, and duly acknowledged as having been taken from that source, where it was published in original matter. We now find, however, that the article originally appeared in the Bulletin of Pharmacy, from which paper it was specially prepared by the author, and we desire to express regret for inadvertently giving credit where not due. Such venial errors are at times unavoidable in the face of the peculiar system followed by many editors, who seem to prefer to take responsibilities they have not incurred rather than quote the source of their "original" articles, translations, and abstracts. In pharmaceutical journalism we are probably the greatest sufferers by this practice, which is indulged in much too freely by some of our transatlantic contemporaries. Whilst only too pleased to find our subject-matter regarded as of sufficient importance to be worthy of more or less extensive reproduction, we venture to submit that it is not too much to expect...
roper acknowledgment to be made in every instance. In such cases as the one which has given occasion for the publication of this note, apologies are due to those who are misled by the omission to furnish such acknowledgment, no less than to the original publisher of the information. It may occasionally happen, in the pressure of business, that the omission is purely inadvertent, but it is stifful, to say the least, to see that journals claiming reputation persistently and continually ignore the most elementary notions of courtesy and honesty.

ADVICE TO STUDENTS.

It has been a frequent cause of complaint that a numerous instances youths had entered upon the practice of pharmacy, as apprentices, whilst possessing but the basiest notions as to what would be required of them before they could become registered as chemists and druggists. More than this, their parents or guardians, and sometimes, infact, themselves, who had been apprenticed, have been unable to dissuade to their enlightenment. To the end that more infinite ideas should prevail, and every apprentice save the opportunity of ascertaining what are the essential requirements before it becomes too late to change his vocation should be furnished with a suitable guide in his chosen path, special articles were published in the “Students’ Number” of the Journal, for the 16th September last. These articles have now been reprinted by the Council of the Pharmaceutical Society in pamphlet form, together with information of interest to pharmaceutical students regarding the scholarships, prizes, examinations, etc., and copies of this “Advice to Students” may be obtained by those interestedapplication to the Registrar, 17, Bloomsbury quare, London, W.C.

NEW HALL AND LABORATORIES IN EDINBURGH.

A meeting was held at the Pharmaceutical Society’s house in Edinburgh on Thursday, the 16th ult., to consider arrangements in connection with the forthcoming opening of the new premises, and it was resolved that on the evening preceding the opening there should be a dinner at the Royal Hotel, at which the President, Vice-President, and secretary of the Society, with other guests, should be entertained. A small committee was appointed to carry out the arrangements, and it was agreed that the chair should be taken on that occasion by Mr. J. LAIDLAW EWING, with Mr. CHARLES KERR, of Dundee, and Mr. W. L. CURRIE, of Glasgow, as Vice-Chairman. Particulars will be found in our advertisement columns, page v. At the Council meeting on Wednesday, the President mentioned that invitations to be present at the dinner had been sent to the members of Council. In complimenting he Committee of the Executive, which has worked so zealously in conferring the new buildings, the President said he hoped they might reflect credit upon Edinburgh, and be the means of advancing the cause which Scottish pharmacists and the council have equal at heart.

CONVERSATIONS IN EDINBURGH.

We understand that the new premises connected with the Pharmaceutical Society’s house in Edin- urgh will be completed very shortly, and that the formal opening of them will take place on the 30th of this month. The new buildings comprise a spacious examination hall and two other rooms, which are to be used for the examinations in chemistry and practical pharmacy. A full description will appear in the Journal at the time of the opening. On that occasion there will be a conversazione (see advt. p. v.), at which the President, Vice-President, and Council of the Society request the honour of the company of members, associates, and students of the Society, and at the Council Meeting the President expressed a hope that as many of the members of Council as could conveniently do so would attend the reception.

NOTES.

The opening meeting of the School of Pharmacy Students’ Association will be held on Thursday, November 15, at 7 p.m., when the introductory address will be given on the occasion by Mr. ROBERT HAMPSON, Treasurer of the Pharmaceutical Society.

The annual conversations in connection with the Chemists’ Assistants’ Association will be held at the Portman Rooms, Baker Street, on Thursday, 15th inst., commencing at 8 p.m. There will be an exhibition of electric, photographic, and microscopic appliances, followed at 9 p.m. by a concert, and at 10.15 by dancing.

We report a conviction at Dumfries, under the Sale of Food and Drugs Act, for the sale of simple carbonated water as soda or potash water (p. 390). This is understood to be a test case, proceedings having been instituted against several individuals.

The additions to the Owens College Medical School, Manchester, formally opened on Tuesday last by the Duke of Devonshire, include two large lecture theatres with accommodation for 350 and 260 students respectively, laboratories for practical and chemical physiology, histology, pathology and pathological chemistry, bacteriology, toxicology, etc.; a research laboratory; galvanometer, optical, photographic, and other rooms for special purposes.

The Liverpool Chemists’ Association held a meeting, on the 26th ult., to discuss certain B.P. remedies, the report of which has only now reached us. Unfortunately the notes sent of Mr. Cowley’s paper were too fragmentary to be of much practical use, but the abstract given at page 389 fairly represents as much of them as was intelligible.

ALDERMAN W. GOWAN CROSS, of Shrewsbury, Vice-President of the Pharmaceutical Society, has been selected to fill the office of Mayor of that borough for the ensuing year, his name would be submitted on Friday, November 9, for election in the ordinary course.

Mr. H. BARTLETT, of Banbury, local secretary to the Pharmaceutical Society, has again been returned a member of the local corporation in the Conservative interest.

Owing to pressure on our space we are compelled to defer the publication of several notes.
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.
Wednesday, November 7, 1894.

Present—

MR. MICHAEL CARTER-THOMPSON, PRESIDENT.

MR. WILLIAM GOWEN CROSS, VICE-PRESIDENT.

Masons: Allen, Atkins, Bottle, Gosting, Greenough, Grose, Hampson, Hills, Martin, Martinale, Newsholme, Richardson, Schacht, and Young.

The minutes of the previous meeting were read and confirmed.

ELECTION OF MEMBERS.
The following, having passed the Major examination, and tendered their subscriptions for the current year, were elected "Members" of the Society:

- Burrows, Harry Southgate.
- Davies, Herbert Fagot Cheltenham.
- Gilby, Francis Johnford.
- King, Charles Edward Berkhamsted.

ELECTION OF ASSOCIATES.
The following, having passed the Minor examination, and tendered (as paid as Students) their subscriptions for the current year, were elected "Associates" of the Society:

- Amiss, Albert Edward London.
- Angel, Edward Charles London.
- Appleby, Percy Keighley.
- Ault, Percy Mansfield.
- Brack, David George South Shields.
- Bryant, Nicholas J. Andrew Truro.
- Charlesworth, Chas. Edward Manchester.
- Clegborn, James London.
- Coward, Miles Keswick.
- Gibbon, George Shaw West Hartlepool.
- Jenkins, Morris William St. Clears.
- Jones, William Miall Aberystwith.
- Marshall, John George Alfreton.
- Massey, Cecil Spalding.
- Mirfield, Arthur Houldsworth Lasswade.
- Mitchell, Henry Searle Truro.
- Morrey, George Market Drayton.
- Monticola, George Briggs Eastleigh.
- Neathcoast, Harry William Ely.
- Pendlebury, James Manchester.
- Potter, Henry Arthur Poole.
- Riet, William King Southampton.
- Scruby, John Charles London.
- Smith, Charles Liandudno.
- Stratton, William George Uckfield.
- Swafield, John Phillips Dartmouth.
- Taylor, Charles John Sandgate.
- Thomas, Hugh William Carnarvon.
- Thomas, John Oliver London.
- Titus, George Francis Ashford.
- Wardley, Thomas Dalton-in-Furness.
- Watson, David Glasgow.
- White, Henry Fox Clifton.
- Williams, David Isaac Llanwyrtyd Wells.
- Williams, John Hills.
- Woodiffe, Henry Grayson Bridlington.

Moore, Thomas Henry Grimsby.
Wilson, Robert William Sunderland.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a nominal restoration fee of one shilling.

RESTORATIONS TO THE REGISTER.
The names of the following persons were restored to the Register of Chemists and Druggists:

- Alfred Boyce, Lyndhurst House, Worthing.
- William George Duck, 12, St. John Square, Cardiff.
- Frederick Gibson, The Mount, Fleetwood.
- George Johnson, Sutton Coldfield.

REPORT OF FINANCE COMMITTEE.
The report of this Committee was of the usual character, and recommended the payment of sundry accounts.

The President (as Chairman of the Committee), is moving the adoption of the report and recommendations, said there was nothing special to call attention to, either as regards the receipts or payments. The balance in hand to the credit of the Benevolent Fund was £247, which might seem relatively large, but a great deal more than that would be required to pay the annuities in January, and the grants to be made in the meanwhile. No addition had been made to either the Donation account or Orphan Fund account.

The motion was unanimously agreed to.

REPORT OF BENEFICIAL FUND COMMITTEE.
The report of this Committee included a recommendation of the following grants:

- £10 to the widow (64) of a member, who has had seven previous grants amounting to £60. (Coonan, Hants).
- £10 to a registered chemist and druggist (61) partially crippled, and unable to stand for long at a time. (Goole).
- £13 to the widow (61) of a registered chemist and druggist suffering from chronic ulceration of the leg. She has had nine previous grants amounting to £73. (Gloce).
- £10 to a registered chemist and druggist (21), who had a grant of £10 in October, 1893. He has a wife (61) to support, and an invalid daughter with three children lives with him, her husband having lost all his property, and being now out of employment. (London).
- £20 to a member, who was for many years a local secretary. He had to assign everything for the benefit of his creditors. He is badly ruptured and quite unable to work. (Barry).

Three other cases were deferred for further consideration, and one was not entertained.

The Vice-President, without comment, moved the reception and adoption of the report.

Mr. Hampson said he much regretted that he had not been supported in his suggestion to the Committee that seven annuities should be elected next month instead of four, seeing that since the Committee made its recommendation three annuities had passed away. He wished it could have been done, as it would save a great deal of trouble and expense to the candidates.

The Vice-President said it was hardly necessary to make any reply to his friend, Mr. Hampson, beyond saying that the question was settled last month. The Committee did not feel justified, looking at the
The Librarian had presented a report on the annual meeting of the Library Association, held at Belfast.

The Curator's report had been received, and included the following particulars:

<table>
<thead>
<tr>
<th>July</th>
<th>Morning</th>
<th>Total</th>
<th>Highest</th>
<th>Lowest</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>

<td>7</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

Donations to the Museum had been announced (Pharm. J. 22, October 20, p. 319), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

Applications for specimens had been received from Professor Johnson, of the Science and Art Museum, and from Dr. Duffy, Professor of Materia Medica at the College of Surgeons' Museum at Dublin.

A set of dried specimens of indigenous medicinal plants had been forwarded to the Three Towns and District Association at Plymouth, and a letter of thanks had been received from the Secretary of the Association.

Duplicate specimens of drugs had been forwarded to the Kolonial Museum at Haarlem.

The Committee recommended that the pamphlet, "Advice to Students," containing educational matter reprinted from the Journal, be printed for use in the Secretary's office after revision by the President.

The President (as Chairman of the Committee) moved the adoption of the report and recommendations. He said the business at the last meeting was of a purely-formal character, and he need not detain the Council by any remarks upon it. The little pamphlet referred to was designed to take the place of the "Hints to Students," written originally by Jacob Bell.

Local Secretaries.*

The President said this was the month in which it was usual to appoint local secretaries, and the list having been gone through in the usual way, he moved the appointment of the following gentlemen, which was carried:

- District
- Local Secretary

Aberdeen
- Strachan, Alexander

Aberystwith
- Wyne, Edward P.

Abingdon
- Smith, William F.

Airdrie
- Harvie, John

Alloa
- Barbour, John

Andover
- Bienvenu, John

Arbroath
- Robertson, John

Ashbourne
- Bradley, Edwin S.

Ashford
- Ingall, Joseph

Ashton-under-Lyne
- Bostock, John W.

Aylesbury
- Palmer, Edwin T.

Ayr
- McGregor, Adam

Banbury
- Bartlett, Hubert

Banff
- Alexander, William

Bangor
- Jones, Owen

Barking
- Ridley, Charles H.

Barnet
- Young, R. Fisher

Barnsley
- Eastwood, Lewis

Barnstable
- Goss, Samuel

Barrow-in-Furness
- Chapman, Leonard P.

Bath
- Appleby, Edward J.

Bedford
- Taylor, James B.

Belper
- Calvert, James

- Local Secretaries are appointed in all towns in Great Britain (except London and Edinburgh) which return a Member or Members to Parliament, and in such other towns as contain not less than three Members of the Society or Associates in Business.

THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS. [November 10, 1894

District. 
Wokingham Rednal, William R. 
Wolverhampton Gibson, Frederic John. 
Woodbridge Betts, Alick Stephen. 
Worcester George, Henry. 
Worthing Cortis, Arthur Brownhill. 
Wrexham Edisbury, James Fisher. 
Wycombe Wilford, Josiah. 
Yarmouth Foll, William S. 
Yeovil Wright, Alfred. 
York Sowrey, Joseph. 

The President said that with reference to some changes in the list he ought to mention that they had lost the services of Mr. Rinn- 
mont, of Glasgow, who was unfortunately suffering from impaired health, having recently had to resign his position on the Board of Examiners from the same cause. Many of them had been associated with him for many years, and though they had sometime criticised his action with regard to pharmaceutical politics, they all felt that he was a typical pharmaceutical chemist, and did credit to the craft. He was a very capable man of science, and if he had enjoyed more robust health would no doubt have done even more than he had for the Society. Mr. Parkinson, of Liverpool, had been local secretary for some years, and deserved the thanks of the Society. Mr. Barnard Proctor, of Newcastle, had only held office a year or two, but he had written a characteristic letter, in which he said he was getting an old fogey, and hoped he had found it out early enough not to make a fool of himself. Mr. Weston, of Ventnor, had retired from business, and Mr. Coldwell, of Malvern, had also retired, and was succeeded in business and in office by one of the Society’s Bell scholars. Several other gentlemen had thought it their duty from various reasons to resign their positions, and he might say with regard to them all that the Council appreciated the services they had rendered, and thanked them accordingly.

SUPERINTENDENTS OF WRITTEN EXAMINATIONS.

It was resolved that superintendents of written examinations be appointed in the same centres as last year, and that the appointments be offered to the local secretaries at those centres.

ASSISTANT LOCAL SECRETARIES.

The President said it was proposed to appoint a certain number of assistant local secretaries in some of the larger centres, but the nominations had not yet all been received, and therefore this would be deferred till next month. The usual plan was for the local secretaries themselves to submit names for the approval of the Council.

DIVISIONAL SECRETARY.

The President moved the appointment of Mr. H. H. Preece, 30, Church Street, Camberwell, as Divisional Secretary for Dulwich in the place of Mr. Silvers, who had unfortunately died at a comparatively early age from cancer. The motion was carried.

CERTIFICATES IN LIEU OF THE PRELIMINARY EXAMINATION.

The President said an explanation came before the Board of Examiners at its last meeting from Mr. L. Ellul, a Maltese gentleman, asking that a certificate
of matriculation at the University of Malta should be accepted in lieu of the Preliminary examination. The Board of Examiners recommended that the certificate be accepted, but could not do so without the sanction of the Council. He therefore moved that the Board be empowered to accept the certificate in the case of Mr. Ellul.

Mr. Arrowsmith asked if the University of Malta would be put on the list of approved bodies.

The President said no; it was considered better to deal with these cases as they arose.

The motion was agreed to.

MEETINGS OF BOARDS OF EXAMINERS.

The President said it had been suggested that the months of January, April, July, and October should be appointed for the meetings of the Boards of Examiners in 1895.

This, on being put to the meeting, was carried.

GENERAL PURPOSES COMMITTEE.

The report of this Committee included the usual letter from the solicitors, stating the progress made with cases placed in their hands. A large number of defendants had paid penalties before trial, in others judgment had been obtained, and some were awaiting trial.

Several new cases of infringement of the Pharmacy Acts were reported to the Committee, and proceedings were recommended.

The legal portion of the report was as usual taken in charge.

The Committee recommended that the local list of subscribers to the Benevolent Fund, hitherto published in the Calendar, be omitted in the next issue. Also that the Council meetings in January and May, 1895, be held on the second Wednesdays of those months, and that the annual meeting be held on May 22.

The Manchester Pharmaceutical Association Scholarship.

A letter had been received from the founder of this scholarship, suggesting the desirability of certain alterations in the conditions, and the Committee, in accordance therewith, recommended the first three books of Cesar's Commentaries be added to the list of subjects for examination, as an alternative to the first three books of the Aeneid.

The report and recommendations of the Committee were received and adopted. A special resolution was passed authorising the Registrar to take proceedings against the persons named.

OPENING OF THE SOCIETY'S NEW HALL AND LABORATORIES IN EDINBURGH.

The President said that they had received an intimation that the new Hall and Laboratories in the Society's house in Edinburgh, which had been in the course of erection during the past eight or nine months, would be opened in about a fortnight. It had been suggested that opportunity might advantageously be taken of the proceedings to hold a reception or sort of house warming in the new premises. He knew how zealously the Committee of the Executive which had had charge of the building had worked, and he thought it had been very appropriately suggested that the reception should be held by the Council in the Society's house on the occasion of the opening of the premises on Friday, November 30, and he hoped as many of the members of the Council as could conveniently do so would attend. This was a subject which the Executive had no power to deal with without instructions from the Council, and he would suggest that they might properly pass a resolution—as he would ask them to do—that a conversation be held, and the Executive for General Purposes be authorised to take the necessary steps for issuing invitations and to carry out the details. Although he himself had not had the opportunity of inspecting the premises, some of his colleagues had, and he understood from them and from the Editor of the Journal that the laboratories and rooms were extremely well arranged and most appropriate to the purposes in view. He trusted they might reflect credit on Edinburgh, and be the means of advancing a cause which their northern friends had equally at heart with themselves, and he doubted not they would appreciate the practical interest the Society would show in the matter. He therefore suggested the following proposition:—

"That a conversation be held in the Society's house in Edinburgh on Friday, November 30, on the occasion of the opening of the Society's new hall and laboratories in York Place, and that the Executive of the North British branch be authorised to take the requisite steps for carrying this resolution into effect, and to issue the invitations in the name of the President, Vice President, and Council of the Pharmaceutical Society of Great Britain."

The Treasurer accordingly proposed, and Mr. Greenish seconded, the adoption of this motion, which was carried unanimously.

DINNER OF SCOTTISH PHARMACISTS.

The President said that the members and associates of the Society in Edinburgh proposed to give a complimentary dinner the night before the reception, and they had graciously invited every member of this Council to attend. He suggested that the receipt of this courteous invitation be promptly acknowledged by the Members of Council.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The President said that Mr. Morley, the hon. sec. of the Chemists' Assistants' Association, had forwarded for the consideration of the Council of the Pharmaceutical Society a copy of a resolution adopted by the Chemists' Assistants' Association at a meeting held on October 18, the result of a discussion raised by the reading of a paper by Mr. E. H. Gane, entitled "The duties of the Pharmaceutical Society as an educational body"—"That this meeting of the Chemists' Assistants' Association is of opinion that a course of post-graduate lectures and laboratory demonstrations would be appreciated and supported, and requests the Council of the Pharmaceutical Society to consider the advisability of providing such a course during the coming winter." He suggested that this matter be referred to the Library Committee for consideration, and this was agreed to.

A letter was also read from the Secretary of the Nova Scotia Institute, thanking the President and Council for their courtesy in sending a copy of the Journal.

PROCEEDINGS OF SOCIETIES IN LONDON.

CHEMICAL SOCIETY.

The opening meeting of the session was held on Thursday, November 1, the President, Professor Armstrong, F.R.S. In Franklin. Before proceeding to the reading of papers, the President suggested that instead of reading the qualifications and the names of the proposers of candidates for election into the Society, only the names of the candidates should be read. This received approval from the Fellows present, and after about fifteen candidates and other formal business transacted, Mr. MacDonald gave an account of the work done by himself and Professor D. O. Mossan on "The Action of Nitric Oxide on Sodium Ethylate." This was a preliminary notice, necessitated by the publication (Ber. xxvii., 1507) of a
paper covering the same ground, by Traube. Nitric oxide gas is absorbed by sodium ethylate, and the sodium salt of nitroso acetic acid, and from analysis of various other salts which were prepared the authors arrive at the formula for the acid—\( \text{CH}_3\text{N}_2\text{H}_4\text{O} \). The acid itself when prepared from the copper salt is found to be unstable. They also found this acid produced when nitric oxide was passed into a mixture of sodium amide and alcohol. Traube and coworkers found that a similar reaction occurred between acetone, acetic acid and nitric oxide, according to the equation:

\[
\text{CH}_3\text{CO-CH}_3 + \text{NO} + 3\text{NaOH} = \text{CH}_3\text{COONa} + \text{H}_2\text{C} (\text{NO}_2\text{ONa})_2 + \text{H}_2\text{O}
\]

The salt so obtained by the authors and Traube are identical.

In conclusion, they gave the probable formula for the acid based on the reactions and the fact that the acid gave Liebermann's reaction for the nitroso group, the formula being as follows:

\[
\text{CH}_3 \cdot (\text{NO}_2\text{ONa})_2
\]

The next paper was by Mr. A. F. Laurie, M.A., on "The Electro-motive Force of Alloys in a Voltaic Cell." Tests were conducted in order to throw light on the vexed question—the composition of alloys, whether chemical compounds or mixtures. If in a voltaic cell the copper and zinc elements are attached to a Thompson's Electrometer, an electromotive force is noticed. If, however, the zinc be replaced by copper, no current is produced, but when the Cu is replaced by a little zinc by means of a battery, deposition on the surface or mechanical attachment, the E.M.F. at once rises to the maximum. If, however, a chemical compound is formed, the E.M.F. does not so rise. It is possible then by noticing the E.M.F. to determine whether alloys contain chemical compounds or are mere mixtures. In this way the author showed that only one alloy, tin-gold, is a chemical compound, the others—tin-blamuth, lead-blamuth, etc., being mixtures. This supports previous conclusions derived from studies of the electrical conductivity of alloys. He also found evidence that in certain alloys there seemed to be something of the nature of solution between the metals.

The last paper read was by Dr. Bone on the incomplete combustion of gaseous carbon compounds, and dealt with the incomplete combustion of mixtures of acetylene, oxygen and nitrogen, etc., after which the meeting terminated.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting held on Thursday, November 1, the President, Mr. R. H. Jones, in the chair, a paper was read on "Recent Advance in Photography" by Mr. E. W. Hill.

After a brief account of the early history of photography, the author drew attention to several new developments which had been introduced of late years to take the place of "Pyro," and amongst the number he mentioned "Bixonogen," glycine, amidol, hydrocinnarase. He was described as "an indefatigable producer of "Isochromatic plates" in photographing colored objects. When a photograph is taken of a coloured object, e.g., a picture or group of flowers, it is noticed that none of the effect of light and shade due to colour is reproduced. This is accounted for by the difference of effect produced by the rays of light on the retina of the eye and on the silver salt in the photographic film respectively. The yellow rays, for example, possess the greatest illuminating power, but act only feebly on the silver salt. Thus, on an ordinary plate the portion actet on by the rays of the greatest illuminating power suffers the least chemical change, the result being the plate is quite black. If, however, the gelatin emulsion of haloid silver salts is treated with eosine, and the so-called "pink emulsion" spread on the plates, on the light being allowed to pass through a screen of transparent red glass before reaching the sensitive film, the lights and shades obtained in the photographs by this method approximate much nearer to the actual effects produced than those obtained by the use of ordinary plates. It is thus rendered possible by the use of these isochromatic plates to photograph oil paintings, etc., and specimens of photographs taken with ordinary and isochromatic plates of the same object were produced. The principle of "spectrum" photography was then explained, how by using a background of mercury in contact with the film a negative was obtained which showed all the colours of the spectrum in their correct tints. Since this method only yields one negative, and this cannot be amplified by the method just described, it is clear that the method must be greatly improved before it is of any practical value. Another method has been used for obtaining "photographs in colours," by means of which any number of duplicates can be obtained. The principle consists in obtaining three negatives by the use of screens of the three primary colours—red, blue, yellow. From these negatives three plates are produced by sinterography, and the paper is printed in the different colours superposed on one another by the zinc plates obtained from the negatives. Reference was then made to the application of photography in astronomic science, to the photographs of star-clouds and galaxies, and the discovery of binary stars and their movements by the spectroscope, such a movement resulting in the displacement of lines of the spectra which are photographed. The application of photography in "high-speed photography," such as the production of pictures of the splash of drops and that of a rifle bullet in motion, showing a pad of compressed air in front of the projectile, was briefly noticed, and the author concluded his paper by a brief reference to the different methods of photography and the use of the camera in medicine.

The President said that chemists should possess some knowledge of photography, since amateurs frequently came to them for advice as well as to be supplied with poisons which could be obtained from them alone. Messrs. Morley and Crouch must have the relations between electricity and light worked out by Hertz and Clerk Maxwell, and Mr. Hart followed with a few remarks on lenses, noticing in particular a new form, the "Telephotograph lens," by means of which photographs of objects at a distance could be obtained of large size without using long exposure cameras. Mr. R. J. Jowett made a few remarks on the help photography had given to astronomy, in particular with regard to those interesting objects—nebulae. Mr. Stegg, referring to the eosine required to prepare the pink emulsion, said that the eosine of commerce varied very much. Mr. Hill having briefly replied, the meeting terminated.

ROYAL MICROSCOPICAL SOCIETY.

A meeting of this Society was held on October 1st, the Rev. Edmund Carr in the chair. Dr. W. E. Dallinger, F.R.S., described a new model microscope which had been made by Messrs. Watson and Mess. Ross exhibited examples of the new scopes. Mr. R. T. Lewis exhibited some parasites which had been found upon a pigeon from Ipswich, Durban, Dr. H. Stolterfoth's paper "On the Genus Corethron" was read by Professor Jeffrey Bell. Mr. E. B. Green read a paper "On some Parasitic Growths on the Root-hairs of Plants," concerning which Mr. A. W. Bennett took the same remarks. Professor Bell called attention to the loss the Society had suffered by the death of Dr. G. E. Binks, a former Secretary. Mr. F. Chapman gave a résumé of part of his paper on the "Foraminifera of the Gault of Folkestone."
The Chairman and Professor Bell made a few remarks on Mr. Chapman's contribution. Owing to the absence of the author, Mr. Nelson's paper "On the Measuring of the Refractive Indices of Various Media" was deferred next meeting on November 21.

Western Chemists' Association (of London).

At a meeting of the Committee, held on October 31, the following gentlemen were elected officers for the ensuing year: President, Mr. R. H. Parker; Vice-President, Mr. J. C. Hyland; Hon. Treasurer, Mr. H. Matthews; Hon. Secretaries, Mr. Herbert Cracknell and Mr. A. Dyson.

Provincial Transactions.

Brighton Junior Association of Pharmacy.

This Association held a musical and social meeting a Wednesday, November 1, under the chairmanship of Mr. W. H. Gibbons. There was a large attendance, and the contributions to the programme were very numerous and well rendered. Mr. E. Hedgcock officiated at the lano. Great credit is due to the energetic Hon. secretary (Mr. F. A. Crowhurst) for the successful evening.

Liverpool Pharmaceutical Students' Society.

On Thursday evening, November 1, at the University College, Liverpool, an interesting historical lecture was delivered to a large number of members of the above Society, by Mr. Charles Sharp, F.L.S., styled "The Land of Green Ginger." At the close of the evening a hearty vote of thanks was accorded to the lecturer.

Liverpool Chemists' Association.

At a general meeting of this Association on Thursday, October 28, Mr. M. Conroy in the chair, five new members were elected.

Mr. John Smith referred to Mr. Parkinson's retirence from the office of local secretary for the district, and thought he ought not to be allowed to sever his official connection with the Pharmaceutical Society without being thanked by the chemists of Liverpool for the faithful and energetic manner in which he had executed his duties. He knew that he expressed the moral feeling when he said that they greatly regretted that Mr. Parkinson had arrived at that decision. The chairman, Mr. Cowley, and others endorsed what had been said, and a vote of thanks to Mr. Parkinson was heartily accorded.

Mr. John Smith was elected President for the ensuing year.

Mr. R. C. Cowley then read a paper on "Some Drugs and Chemicals of the B.P.

In this the drugs were dealt with more especially reference to the approaching revision of the British Pharmacopoeia. Gum acacia, B.P., it was suggested, means the gum of Acacia senegal from Sudan, and the geographical source should be specified accordingly, as climatic difference produced variations in the gum. Vinegar should be omitted from the B.P., or the quantity of total solids be specified. Acid, hydrobromic, dil. if made from PB, should be free from H₂SO₄, and this alternative preparation should therefore be official. Acid, acetic, should be described less vaguely, and more frequent tests be imposed to ensure its purity. Adips. should be free from cotton-seed oil, and a test to prevent adulteration might be added. Chrysarobin should be more explicitly described. Confections of opium, pepper, scammony, and tarantin are nearly obsolete. Ergot should be as fresh as possible. Fluid extracts contain more of the active principles than infusions, and are therefore preferable. Solid extracts should be standardised. Ferri fumarate usually contains a large proportion of ferric ascorbinate, which is less soluble than the ferrous salt. Ferri carbo. aceti should be renewed frequently. Ferrous salts should be determined by potassium permanganate instead of the bi-chromate, and reduced from the mercuric chloride of the Glycerin of the B.P., which was often too hard for a pill excipient. Infusions should only be used when fresh. Lith. terebinth. should have its consistency specified. Lupulin should not yield 15 per cent. of ash. Manns might be distinguished by the amount of mannite present. Fil. phosphors should have an improved formula. Reference was also made to the occasional presence of methylated spirit in spirit. eu. nig. tinctures; the methods of preparation of syrups and tinctures; the suitability of paraffins as the vehicle in ointments, etc., etc.

The Chairman said that Mr. Cowley had covered a lot of ground, and had provided a very fine footing for discussion. Some of the suggestions offered were good, but others he could not altogether approve of. It would be difficult to insist that certain drugs or their preparations should not be employed if kept in stock beyond a stated time. The list of fluid extracts should be enlarged, as they were really excellent preparations, and much superior to infusions. He did not see any good reason for departing from the bi-chromate test for ferrous preparations; he used it extensively, and always found it satisfactory. Percollation was undoubtedly a very useful method of extracting certain drugs, but on the whole the B.P. methods were very satisfactory. He would give no encouragement to the use of water for displacing spirit. It was important for various reasons that tinctures should be of full alcoholic strength, and this could not be guaranteed where water was used for displacement. He would be glad to see a test for the presence of methylated spirit under spirit of nitrates ether. Mr. Wokes had found that glycerin of tragacanth with a few drops of syrup was a better excipient than the former alone. A small quantity of chloroform was an excellent preservative for infusions. He recommended one part of heavy magnesium and two of the light for Paraffin oil. He had not found that displacement by water was useful in some of the rectified spirit tinctures, but the process required to be carefully watched.

Mr. J. Smith thought recipes for poultices were no more required in the Pharmacopoeia than for bees: the fluid extract could, he believed, be made more satisfactory by percolation than by boiling or maceration. As to tinctures, unless the drug was in a finely powdered state, percolation alone was quite inadequate. The relative value of percolation and maceration depended entirely upon the state of division of the drug, and this was largely determined by the nature of the solvent by water, which would probably answer well in the case of a powder. He considered the paraffin bases very suitable for some ointments. Respecting names of new remedies, he remarked that the B.P. authorities had never made proprietary articles official.

Mr. Buck commented upon several of Mr. Cowley's suggestions, and proposed the use of a little more water in the preparation of turpentine liniment.

Mr. Hornblower thought that as the confectograms were still used to no small extent they were likely to remain in the Pharmacapoeia, and that the directions for making the cataplasmata were a guide as to what poultices should be. He endorsed the chairman's remarks as to the difficulty, perhaps the impossibility,
of carrying out restrictions as to limit of time after which drugs should not be used. His experience was that B.P. syrup did crystallise, and he attributed that to the greater purity of sugar which now contains less water. He was in favour of the maceration and percolation process for tinctures as now ordered. Displacement by water was quite useless when operating with large quantities. He considered it important that tests for methylated spirit in spirit of nitrous ether should be included in the Pharmacopoeia.

Mr. Cowley, in replying, said that many of the members had greater experience than himself in manufacturing, and had been able to offer much useful criticism. The chairman and Mr. Hornblower had dealt very effectively with many of the subjects of his remarks. He regretted that, having to come forward at short notice, and being unable from unavoidable circumstances to make the experiments he wished, he had to submit his paper in an incomplete form.

Messrs. Maw, Son and Thompson exhibited some pharmaceutical apparatus at the meeting, including a set of embossing glass in the metallic press, pipping press, a French tincture press, outmixer, etc., etc.

Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND
PHARMACUTICAL ASSOCIATION.

The first ordinary meeting of this Association was held on Thursday, October 1, Mr. John Foster, Vice-President, in the chair. The President being unable to attend, the discussion of the resolution submitted at the meeting held on June 28 last, by Mr. J. Anderson Russell, and adjourned from that meeting, was again brought forward. The seconder, Mr. D. S. Robertson, had communicated his inability to be at the meeting, and Mr. Russell was requested to reintroduce the business. Mr. Russell, in a few words, referred the members to the report of former meeting in the Pharmaceutical Journal of July 7, and shortly recapitulated the clauses of the resolution.

Mr. Laing said the business before the meeting was the adoption or rejection of Mr. Russell's motion. If they were content with the present condition of things there was no use in discussing it. He was not content, and would support it. It asked for the registration of open shops for the sale of all drugs, and confined the sale to registered druggists.

Mr. Moir said in some parts he entirely agreed with Mr. Russell, but that all persons engaged in pharmacy be registered he entirely agreed with, also that open shops be registered, and that registration be maintained under an annual registration fee, which was quite right. But the fourth clause, that medicines be compounded only by registered graduates only, he was not so sure about. He would be very grateful if it were granted, but he was firmly persuaded no legislature would grant it, no sensible men would listen to it.

Mr. Robb considered that the legislature would do very little on the lines of Mr. Russell's resolution. It sought to encourage free trade and not monopoly. We had got into many vexatious things through the '68 Act. He thought education a good thing for everyone, and no one could get too much of it, but so far as conducting their businesses was concerned, the Society's educational plans were of no service. He would rather they be reactionary, do away with the Pharmacy Acts, and have free trade not hampered in any way.

Mr. Boyd said the proposed resolution omitted mention of limited companies, and they led to a very unsatisfactory state of things. He would like to get a better footing, but he disagreed with having annual fees be like a state of slavery. He had been connected with the Pharmaceutical Society since passing his first examination, and had a regard for it, but he would not agree to give it power to erase names from the Register. If they were Parliament seeking a monopoly, they would prefer the privileges they already enjoyed.

Mr. J. Bruce thought the motion should be drawn, lest they be made the laughing stock of the country.

Mr. Robinson said the motion did not relate itself into anything palpable enough. He thought some benefit might be gained if the sale of poisons was as closely watched as the sale of spirits, so sales could be traced in all instances. He would a clause giving sole control of the poison schedule to registered persons only, who should get the remuneration for distributing poisons.

Mr. Moir suggested that the motion should be amended in Bill made by Mr. Russell, the penal clause amended, and again submitted to the Association. This was put to the meeting and agreed to.

Mr. David M'Ney, Thornhill, joined the Association and the business was concluded.

Parliamentary and Law Proceedings

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACTS.

DEFECTIVE SODA AND POTASH WATER.

In Dumfries Sheriff Court, on November 2, William Johnstone, chemist. Dunfries, was charged with a contravention of the Sale of Food and Drugs Act by selling to the inspector as soda water in bottles of carbonated water, which contained no carbonate of soda, and other three bottles of potash water, which contained no bicarbonate of potash. W. Thomson, solicitor, delivered a plea of guilty on his behalf, accompanied with the explanation to the first charge, that this was the best usually sold as soda water, and that prepared as described in the British Pharmacopoeia it would contain so much alkali as to be not only disagreeable to it but injurious when employed as a beverage. As to the potash water, he stated that soda water had been given instead through the fault of an apprentice. Sheriff Campion imposed a penalty of two guineas and a guinea of expenses.—Scottsm.

POISONING CASES AND INQUESTS.

CHILD POISONED BY MORPHINE.

Elizabeth Cannon, aged 14 months, of John Edward Street, Reddish, died on Thursday, November 1, from the effects of an overdose of morphine contained in a cordial. Verdict: "Death by misadventure."—Manchester Guardian.

CARBOLIC ACID CASES.

On October 31, a little girl named Bain, living at Ramsey, Isle of Man, drank some carbolic acid from half-pint beer bottle and died a few hours afterwards.—Evening News and Post.

Thomas Price, aged 18, of Hughes Street, Ardwick died on Wednesday, October 31, after taking carbolic acid. Verdict: "Suicide whilst insane."—Manchester Courier.
Reviews and Notices of Books.

The general character of the work, which is now expatiated by the publication of this volume, has recently been described in previous notices of the earlier volumes, and it may be added that, in this respect, the volume now issued fully supports the high expectation which the Dictionary of Chemistry has already received. The first 102 pages are devoted to continued description of the phenyl compounds, one of which was dealt with in the third volume. Phosphorus and its compounds occupy the next fifteen pages. Then follows an interesting general article of 50 pages on Photographic Chemistry, by Professor A. H. Kellogg, and the description of compounds related to phthalic acid occupy twelve pages. Immediately following is an article of one hundred pages treating of the physical methods used in chemical investigation which are now becoming of such great importance. The several sections into which this article is divided are written by Dr. Capstick, Mr. George Gladstone, professor Hartley, Professor Ostwald, and Mr. Muir. The next fifty-six pages are occupied with articles on various subjects, including the compounds of Platinum, Pernum, Propyl, etc. A comprehensive article on sixteen pages on the Proteids is written by professor Halliburton. The following 142 pages contain miscellaneous articles, extending from Protocelomic acid to Solanamine, and including Selenium, Silicon, Silver, Sodium, and their compounds. An article on seventy pages on Solutions is written in two sections by Professor Arhenius and Mr. Pickering. Another sixty pages on Specific Volumes is written by Professor Thorpe. Then follow articles on Starch (six pages) and Sugars thirty-six pages, by Mr. Sullivan, those in the intermediate space including Stearic acid, Strontium, Strychnine, and Succhinid, and their compounds. Sulphur and its compounds occupy ninety-two pages; Tannins, written by Dr. Ideal, six pages; Terpenes, written by Professor Tillet, twelve pages, and the remaining 222 pages are chiefly occupied by articles on Thallium, Thorium, Tin, Titanium, Toluic, compounds, Tungsten, Uranium, Ions, and Uric acid, Yannalium, Water, Xylene compounds, Ytrrium, Zinc, Zirconium, and an adendum standing over twenty-five pages contains brief accounts of some of the chief work done in descriptive organic chemistry since the publication of the previous volumes of the Dictionary.

It is no disparagement of the general excellence of the volume to select for special mention three articles on Proteids, Starch, and Sugars as existing chemical knowledge of the substances related to albumin is still very imperfect in comparison with the interest attaching to them as materials connected with the manifestation of organic activity, both in plants and animals. But the amount of work that has been done with a view to unravel their constitution is very considerable, and the references given to original memoirs on the subject, in the course of the article in which the proteids are described, will be very serviceable to those who desire more detailed information than can be comprised in a dictionary article.

The articles on Sugar and Starch relate to a branch of chemistry which has recently received important advance, and they furnish a comprehensive summary of the work done, such as might be expected from the writers' intimate acquaintance with the subject.

The articles on Terpenes and Tannin are in like manner excellent and useful summaries of chemical research. The article on Solutions deals with a very interesting and important subject which has recently engaged the attention of chemists from two opposite points of view, and in order that they may both be presented to the reader, part of the article has been written by the originator of the hypothesis of electrolytic dissociation, while the other part has been written by one of the leading supporters of the hydrate hypothesis.

Considering the vast number of descriptive data which have to be embodied in a work of this kind, it may be open to question whether such a subject as that of solutions, and more especially the one of physical methods, might not be advantageously dealt with in a separate work, as already suggested in regard to the articles on analogous subjects in previous volumes. That some such division of the subject matter might be desirable is indicated by the remark of one of the Editors, that an account of what has been done in the domain of organic chemistry since the previous volumes of the Dictionary was published would occupy many hundred pages. But whatever opinion may be entertained on this point, it is beyond question that, in the Dictionary, chemists are now in possession of a very useful work of reference, for providing which the publishers, editors, and contributors are entitled to a large measure of appreciation and gratitude from those who have need of such a work.

In this part of the work we are introduced to the study of the ultimate structure of plant—protoplasm and its constructive activity being considered at length. Plant-forms as completed structures next engage attention. Thus, the progressive stages in complexity of structure from unicellular plants to plant-bodies are described; then the form of leaf-structures—cotyledons, scale-leaves, foliage-leaves, and floral leaves; and last, the forms of stem-structures. The illustrations are, as usual, well calculated to elucidate the text, and a coloured plate represents the manner in which prickly-pears grow on the plateau of Anahua, Mexico.
New Books and New Editions.

The following are amongst the most recent scientific and technical publications:

CARBON Photographic No. 5 is in the sale of the Amateur Photographer's Library. By E. J. WALL. 18. Hazell, Watson.

THE ROYAL NATURAL HISTORY. By RICHARD LYDEKKER, B.A., F.R.S., etc. Illustrated. 92. Vol. II. F. Warne and Co.

LIFE AND MIND ON THE BASIS OF MODERN MEDICINE. By ROBERT LEWINS, M.D. W. Stewart and Co.

POPULAR NATURAL HISTORY FOR BOYS AND GIRLS. By W. J. GORDON. 28. 6d. The Religious Tract Society.

Obituary.

Notice has been received of the death of the following:

On October 27, Richard Flowerdew, Chemist and Druggist, Eves. (Aged 53.)

On October 31, Samuel Rhodes, Chemist and Druggist, Penrith.

On November 2, Richard Proctor, Chemist and Druggist, Penrith.

On November 5, Ralph Burton, Chemist and Druggist, Manchester. (Aged 61.)

Correspondence.

SALIS Proprietary Medicines.

Sir,—The method suggested in Mr. Viser's letter re the sale of proprietary medicines is not the one I would suggest—to relieve the retailer of the responsibility of selling an article containing a scheduled poison without affixing a poison label and the name with address of seller. Holding the view that I do of the seller being, in the first instance, the manufacturer of such an article, I would suggest that a memorial be obtained from the qualified chemists and druggists in business on its own account (through the local secretary of each division) and presented to the Council of the Pharmaceutical Society, requesting it "By virtue of the powers vested in the Society under the Charter of Incorporation and the Pharmacy Act, to give notice to the manufacturers that any preparation containing a scheduled poison shall have it stated on the wrapper outside the bottle, with the name of the article, the word 'poison,' and name and address of the maker, with a label containing the same information on the bottle, no matter how small a quantity of poison the preparation may contain." Any breach of this Act shall render them liable to proceeding under the Act, to be followed by the same and address of the offender, together with the date of sale, being gazetted as in the case of bankrupts. This last should be done because the Society is precluded from publishing such offences if penalties are paid into court, from fear of such publication being construed as a libel. With reference to our esteemed President's views as to our finding out whether such articles contain a scheduled poison for ourselves—seeing that we have an analyst (Mr. Estes) who can come forward to give evidence in these prosecutions, I maintain that he should be employed to do this for us, and if he finds a case where the Act is infringed, upon his report to the Council pro-

seeds should be taken. Until company trading is an end to by the prosecution of unqualified men directors, and such prosecutions are made public, we will see there be disclaimer in the ranks of qualified men keep aloof from belonging to the Society, saying, 'The Society does not protect our interests.'

Toryquet.

W. J. Rawlinson.

THE NOMENCLATURE OF OFFICIAL REMEDIES.

Sir,—I cannot vest the valuable letter of "Devine" in the issue of October 27, page without giving it earnest approval. I agree with it to toto, and hope each suggestion he has made will be considered at the revision of the British Pharmacopoeia. As I am a progressive man in pharmaceutical matters, I do not shall not be thought retrogressing if I would suggest some of the old titles, which are now exposed to be re-introduced. May I suggest that in these days, so many, and in so many cases, patients can meet a medical man's prescription, that instead of liquor Para, liquor arsenie hydrochlorique, liquor quinhydroxy iodide, liquor morphine hydriol, liquor morphia acetate, the terms liquor fid solutione solutos minerals, liquor Donoveni, liquor para, hyd., and liquor meconii acetat be accepted? In many instances of leading medical men always use these terms.

Hamgate.

Diary of the Week.

SATURDAY, NOVEMBER 10.
Pharmaceutical Football Club v. Brewers, at Woodforde Farm, Shepherd's Bush, at 3.15 p.m.

TUESDAY, NOVEMBER 13.
Royal Photographic Society, at 8 p.m.
A simplified form and improved type of Photographic Lens," by H. Dennis Taylor. Presentation of the Society's Medal.

WEDNESDAY, NOVEMBER 14.
Pharmaceutical Society of Great Britain.
Library, Museum, School, and House Comm. at 11 a.m.

Evening Meeting in London, at 8.30 p.m.

Manchester Pharmaceutical Association, at 7.30 p.m.

OPENING MEETING.

THURSDAY, NOVEMBER 15.
Chemical Society, at 8 p.m.

Liverpool Pharmaceutical Students' Society, at 8 p.m.
"Nostra," by J. Gilbert Jackson.

Retail Prices," by E. C. Mitchell.

Linnean Society of London, at 8.30 p.m.
"A Revision of the British Coptis genus with the two Genera Bradya and Actinomos," by the Scott.

"Recent observations on the plant yielding Bar (Cannabis sativa)," by Dr. D. Prain.

Chemists' Assistants' Association, at 8 p.m.
Annual Conversations at the Fortman Room.

Gloucester Pharmaceutical Association.
"The early History of Botany," by Professor E. School of Pharmacy Students' Association, at 7 p.m.
Election of Officers.

Introductory Address by R. Hampson, Esq.

FRIDAY, NOVEMBER 16.
The Queckett Microscopical Club, at 8 p.m.
Ordinary Meeting.

COMMUNICATIONS, LETTERS, etc., received from Messrs. Antill, Blackburn, Blair, Clarke, Conroy, Hill, Jones, Lunn, Marsden, M'Collough, Mori, Pea, Robins, Steimmel, Thompson, Thomson.
EIGHTEEN MONTHS' COUNCIL WORK.

BY J. BYMER YOUNG.

In venturing to address you on the subject of the Pharmaceutical Society and its doings, I should explain that your indefatigable secretary settled the matter by saying that I ought at least to take my fair share in the work and deliberations of this Association, a suggestion which applies with not less force and pertinence to many more of our members, who, though in all conscience content to rest themselves with admiration to their personal good and to the general weal. The dolce far niente attitude, so greatly affected by pharmacists, is of course luxuriously easy and comfortable enough, but very treacherous. One is apt to find after these "Rip Van Winkle" intervals of indulgent repose, that we have slumbered a little too long—the times have gone ahead of us, whilst we are left woefully behind.

Not much better than the chronic sleeper, is the eternally good-for-nothing, a sort of personal growth, and, like the poor, always with us. This is the individual who is ever prepared to find fault with, and censure, everything that everybody or anybody does, or attempts to do, in the interest of the trade or its organisations. He is never prepared, under any circumstances, either to pro- pound schemes, invent remedies, or suggest methods of any real utility; nor is he willing even to encourage with his sympathy and support those who, in their own way—good, bad, or indifferent—are doing their level best to put things, and keep them, in the middle of the road. It was at first my idea to talk this evening on some one of the many complex scientific subjects relating to our calling. But your secretary has views of his own, and sticking to them like a leech he will not be shaken off. Give us an opportunity for a general discussion on ordinary trade topics! That was his mandate, and so it becomes my brief.

I do not forget, of course, that Pharmacy Acts and examinations, company trading and poison regulations have all had your frequent and careful attention. Still, I do feel that to assent the "mind pharmaceutico," the anxieties and worries that some of illegitimate competition, the consciousness that our remuneration, always absurdly inefficient and inadequate, is, nevertheless, a constantly diminishing quantity—all these, and other matters, are still before us, in painfully bold outline, haunting our mental vision like a perpetual nightmare. Perhaps, therefore, we might do worse than once more devote a few minutes to their discussion.

It is not about eighteen months since I had the privilege of becoming a member of the Pharmaceutical Council, for as a privilege and honour I have always regarded it. I keenly appreciate the fact, and acknowledge with extreme pleasure, that the result of the election, as concerns myself, was entirely due, primarily, to the splendid way in which my candidacy was initiated and supported by this Association and its officers, and indirectly to the valuable help from kindred associations which Manchester friends were willing and able to secure in my interest. This district has emphatically demonstrated the election of a man with the qualities of his nominee, whenever the members of this Association choose to interest themselves in the matter in an active manner. The fault is entirely your own if you are inefficiently represented, either in point of quality or number. It has always been to me a source of satisfaction that you never required from me conformity to any particular policy or line of conduct. I have never felt that I was regarded as a mere delegate with limited power of a purely automatic character. Indeed, I may say frankly that I could not possibly have joined the Council on any such conditions. True, there was an understanding that my sympathies were in accord with a policy of action and progress, rather than of ultra-respectable stagnation, and in the exercise of my privilege as your representative at Bloomsbury Square, I have invariably voted as my judgment dictated. I have never hesitated to express my views with perfect candour on any subject that came before the Council, without any thought as to whether such views were palatable, heterodox, or popular. At the same time a little discussion on things in general will help me to gauge your ideas and wishes, to ascertain your opinions, and so assist very materially in formulating and possibly modifying my own.

I need hardly remind you that most important changes will very soon take effect regarding the examinations. In the first place, it has been decided that no examiner shall retain office for more than four consecutive years, and further, that no examiner shall be eligible for re-election until the expiration of not less than one year. The appointment is, of course, an annual one, and an examiner need not necessarily be continued in office for more than twelve months, but the provision which makes retirement compulsory after four years, is, I think, a wise one, since it makes occasional alteration in the complexion and personnel of the Boards possible without involving friction or annoyance to those retiring. That there should be in existence a constant but gradual process of addition and elimination I am convinced is highly desirable, not only in the case of the Board of Examiners but in that of the Council itself. In the second place it has been decided to strengthen the Board by the appointment, in the purely scientific subjects of chemistry and botany, of a limited number of professional teachers as examiners in those two departments. Their duties will be confined to those subjects only. It is not for one moment to be inferred that the present staff is either inadequate or incompetent in these particular branches, but it is argued, with much show of logic and probability, that gentlemen constantly engaged in teaching botany and chemistry are in a much better position to know what may reasonably be expected from candidates seeking the diplomas of the Society. The art of examining—for art it is—is not necessarily possessed by the profound scholar, or the skilled scientist.

The whole matter was exhaustively investigated by a thoroughly representative committee, whose subsequent report was of such a nature that I had no hesitation in supporting it. At the same time I should not feel disposed to carry this innovation further than the two subjects named. In pharmacy, materia medica, and dispensing, there can be no better examiner than the pharmacist pure and simple. It is hardly likely that anyone here can have
failed to notice with surprise, if not positive consternation, the very high percentage of failures amongst candidates for qualification, especially the Minor. Although I am informed that it is not higher than in the case of most of the scientific and medical examinations, still the amount of rejection does seem enormous, and I determined to try to find out for myself how this deplorable state of affairs came about. With that end in view, I passed the greater portion of a day in the Examination Hall, when I met with every possible courtesy, and saw a number of candidates examined. I can safely say, from what I saw and heard there, that the secret of most of this wholesale "slaughter" is the appalling ignorance and astounding stupidity of the candidates themselves, many of whom are so utterly unprepared that one could not seriously suppose they ever imagined it possible to get through. Indeed, I am given to understand that many do actually enter with the sole idea of seeing the light of day when it is too late—shoer waste of money and waste of time.

It cannot be denied that among those who succeeded in satisfying their examiners, some are distinctly brilliant, and answer with the greatest ease the questions that so effectually bowl over the great majority.

First and foremost, the early education of many candidates must have been lamentably bad. Faulty grammar and erratic spelling, shaky composition and miserably weak descriptive powers, were all unmistakably indicative of defective early training, and it is as impossible for me to believe that the special education of the pharmacist depends very largely upon the general education received before the study of pharmacy is commenced at all—the education of home, school, and association. My opinion is that a still higher, nay a much higher, standard is required as regards the Preliminary, which should certainly be passed before apprenticeship. The youth who finds it difficult to pass a much harder examination than the present Preliminary has surely mistaken his vocation.

I am strongly inclined to think that a compulsory curriculum of study would greatly tend to improve matters, and to ensure thoroughness and solidity of preparation in the scientific and practical subjects—though I am by no means sure that pharmacy with such restrictions, superadded to those now existing, would offer sufficient reward to attract one that is not already in our midst. That is a matter of opinion, but with this we really ought to have no concern. It is our plain duty to maintain a high standard of qualification whatever the consequences may be, and it is not less our duty to make this elevated standard attainable and possible.

I am prepared to believe that it might have the effect of checking somewhat the number of men who are seeking entrance into our business. But seeing that the business is already inordinately crowded, I do not see that this result need embarrass existing chemists, who can have no possible object, advantageous to themselves, in the wholesale manufacture of opponents. At any rate, if we had fewer, we should have very much better men, and that would be ample compensation. The system by which candidates persistently neglect every opportunity for acquiring knowledge during their apprenticeship, and then expect a coach to make modern Solomons of them, by some magic rub of Aladdin's lamp, in a few weeks' hasty-and-akrauly work, is largely accountable for the almost idiotic answers frequently heard during examination; some of those related to me by examiners (mostly pharmaceutical) are amusing enough to bear repetition.

One candidate said that benzoin should always be rejected if it had any white pieces in it. The natives collecting it were in the habit of picking pieces of chalk into the soft places. Another made argent. nit. by putting silver into nitric acid, and allowing it to crystallise out when it had ceased working. This answer was refreshingly brief, but lacking a little in detail.

A botanical examinee, in naming a daisy leaf, said that "Dens innis" meant lion's den, an answer more than one heard in the Examination Hall. Another, when asked to describe the male and female organs of a plant, frankly expressed his surprise that they had any. Another thought the "muscat" was obtained from the "muscate", but whether the "muscate" of Alexandria he could not say. Still another individual said that sq. camph. was made by floating a piece of camphor on the surface of the water, the air assisting the camphor to dissolve. Probably the candidate was in this instance relying on his practical knowledge, for many of us have seen it made that way, but not the B.P. method. Ayvazopoulus was the name of a man. Creo tartar was the precipitate which came to the surface when salts of tartar were dissolved in water. Nitrate of silver pills should be coated to prevent them dissolving and injuring the coat of the stomach. Cold water is used in making infusion of calumba, because hot would dissolve the galls. Pepsin is made by scraping the back of a pig. Another candidate was not quite certain whether veratrum was the sulphate of iron or zinc. The same candidate kindly gave him three months to consider this matter and others, about which he was also equally at sea.

And so every examiner could give numerous instances of answers not less absurd and grotesque, all more or less the result of imperfect reading and hasty, ill-considered, slip-shod work. The probability is that a good many of these men have undergone a process of "cram." I don't use the word in any offensive sense. Considering the quality of the material upon which the private tutor has to operate, one can only wonder that so many men are not thrown out so favourably rejected. A man who has mental food thrust into his brain by a pharmaceutical expert quicker than he can assimilate it, is to my mind crammed. Intellects differ, of course, and one man may and sometimes does, pick up and assimilate more information in three months than another does in three years, but, speaking generally, quickly acquired knowledge is very evanescent.

Even though a crammed man may scramble through the clutches of the examiners he gets little benefit out of his short noted mental superficial work, it soon takes wing, and he straight away forgets what manner of man he was.

I have by no means any desire to depreciate the services of the professional coach, usually inte-
gent and smart, with whom patience must indeed be a virtue. In the present state of affairs the word is a positive necessity to many, and he supposes that for which there is, unfortunately, a demand. Before dismissing this question of examiners I should like to remind you that Mr. Martindale considers the Board ought not to be content with a merely theoretical knowledge of the medical system of weights and measures, but that candidates should be required to show practical familiarity with their use. A recommendation to that effect was recently passed by the Council, but, to my surprise, the examiners did not see their way to adopt it. England is the only first-class power that has refused to adopt a rational system—almost ancient in Germany, France, and Austria—and still chooses to struggle on with her cumbersome, grotesque muddle of terms and quantities, none of which are a constant multiple of anything else. If it is reasonable to expect candidates to know anything at all about the metric system, surely we may reasonably expect that knowledge to be of a practical character, if it is to be of any use. We might as well content ourselves with theory in pharmacy, chemistry, or botany.

It is the book pharmacist who bungles the emulsion, the expert at equations who puts borax into the pot, nit, drawer, and the theoretical botanist who makes inf. gent. co. with rad. belladonna. We all know these purely theoretical men, they "come from Sheffield." I need hardly say that this matter will drop up again, and, I hope, with more satisfactory results.

You need not be reminded that the Council has for the third time represented to the Privy Council the absolute necessity for adding carbolic acid to the Poisons Schedule. However, that august body, I regret to say, in the fulness of its wisdom, has not seen fit to acquiesce. You are aware, too, that the Council is quite powerless in the matter, and can make no alteration or addition to the Schedule without the authority and consent of the Privy Council. That body has been fully informed, it has been conclusively shown, that more deaths are caused by carbolic acid than by any other poison now included in the Schedule. The number of accidental poisonings has increased, and recommendations from coroners and juries are becoming quite frequent. I know that wisdom percolates very slowly into the veins of the permanent official, "who moves in a mysterious way" and is not altogether like other men, but public opinion cannot much longer be resisted, nor can public safety be much longer ignored. In the meantime we can only go on with our periodic applications, each one of which becomes stronger and stronger with accumulated evidence of urgent necessity and disaster. The only reason vouchsafed for refusing to schedule carbolic acid is—that being too much in popular demand public convenience would suffer, and that any restriction placed upon its sale might be especially harmful whilst epidemics were prevalent. Well, distinguished gentlemen should be content to be Judas.

Under the circumstances you will see no little ease taking that mineral acids shall be excluded in the Schedule. Yet the careless way in which these acids are distributed to the public would only justify their inclusion.

A somewhat singular omission occurs in the Poisons Schedule as it now stands, and is one of many instances that might be quoted to show the necessity for its entire revision. Cantharides and all fluid vesicating preparations of it are included. This does not, however, include cantharidin, which, therefore, may be sold without let or hindrance by anyone who chooses. You will have noticed that an unsuccessful attempt has been made by Mr. Hampson and others, including myself, to make some decided alterations in the system by which applicants for annuities from the Benevolent Fund are elected.

It is at present the duty of the Benevolent Fund Committee to select from the applications made such cases as appear to be thoroughly deserving and eligible. A list of these is presented to the Council for confirmation, and becomes a "list of approved candidates." The number is quite arbitrary, and is nearly always in excess of the number of annuities for disposal. The result is a sort of scramble, which is anything but edifying. A postal canvass is instituted by people in the most destitute circumstances. The candidate who is too poor to expend a considerable amount of money, and is without influential friends to push his case, has little chance of success, at any rate in the first instance. On the other hand, the candidate who is really better off in possessing powerful friends who spare neither labour nor expense, quite probably heads the poll, though he may never have contributed a fraction to the Fund.

Mr. Hampson suggests as a remedy that, instead of compiling a long list of approved candidates, the Committee should select only a number corresponding with the actual number of annuities to be conferred, in other words, that the candidates deemed most eligible should be elected. If the Committee is to be trusted in the matter, and has the safety of the poor at heart, it is not strange that this suggestion was not very far from the mark.

This would mean taking the election completely out of the hands of members of the Society and subscribers to the Fund, and placing it entirely in those of your Executive. How far this may be wise is, of course, open to discussion. A large majority of the Council, though agreeing with us on the question of principle, voted against Mr. Hampson's motion on the ground that taking the election out of the hands of the subscribers themselves would injuriously affect the inflow of subscriptions— which is to say, the Benevolent Fund would suffer.

The Benevolent Fund is a splendid institution, conducted on most democratic lines, most economically and, may I say, lovingly managed. Members and non-members, subscribers and non-subscribers are all equally eligible to participate in its benefits, the only test being that of poverty and merit. It has been of inestimable benefit to scores and scores of our less fortunate brothers, "broken with the last straw," and in the heart as well as estate. This Fund has indeed strong claims on sympathy and support.

In April last the Law and Parliamentary Committee asked for authority to introduce into Parliament a Draft Bill, called The Pharmacy Act Amendment Act, 1894. The object was to render every person whose name appears on the Register of Chemists and Druggists eligible as a member of the Society, to make students associates, and to
provide for the retirement of one third of the Council every year by rotation instead of ballot. This proposal was met by an amendment from Mr. Harrison to the effect that it was not expedient to attempt further legislation until the whole question could be considered.

The Bill claimed to be nothing more than a step in the way of consolidation, and it was unanimously admitted that the introduction of controversial matters at the present time would be utterly futile. Discontent has been expressed as to the constitution of our Society. Time after time it has been urged that there should be perfect equality between pharmacist and chemist and druggist members, and that membership of Council should be as possible for one as for the other. For all the this the proposed Act provided, but with the restriction that the Council shall not at any time contain more than ten members who are not pharmaceutical chemists. This restriction seemed to me most desirable and reasonable, yet, notwithstanding its distinctly broad and democratic nature, it has met with a good deal of opposition. The suggested change in the method of retirement of seven members of Council each year, by rotation instead of ballot, is very desirable. Under the present system, a member who is only just beginning to feel his feet, as it were, is liable to be thrown out by the chances of ballot, after only twelve months' experience. Under the proposed system he would be safe for three years, during which time he would have a fair opportunity to justify his election. There is, moreover, something decidedly objectionable in the "clash" of too much of the lottery and bazaar, too much of "pitch and toss," and really is a little undignified.

Another objection was that the Bill made no provision for exemption from jury service, but this was designedly omitted as certain to provoke opposition. Opinions differ, even on the jury question. Whilst one bemoans his liability, Mr. Martin considers that he is at a disadvantage in being disqualified by Act of Parliament from jury service; at the same time he thought exemption should be granted to the chemist who desired it.

Thought, and echoed, to be too much of the lottery and bazaar, is that just argument which has been used, and with great effect.

If ever the introduction of a Pharmacy Bill is attempted, with the serious intention of abolishing company trading, chemists will do well to make up their minds that they will have to relinquish the Widows Clause. It could not reasonably, logically, and honestly be retained, and it has already done us an immense amount of harm.

When we can present to the House of Commons a rational, workable Bill, dealing in a business-like manner with education, curriculum consolidation, and company trading—when we show that such a Bill is backed up and supported loyally and enthusiastically by every chemist on the Register, and not simply by the few we belong to the Society—then, and not until the shall we deserve success and possibly attain it.

Probably in no other occupation is there such want of internal organisation—such utter neglect of existing facilities for combined action in the interests of the entire body. The advantages in this respect offered by the Society, both for protection or defence, could not well be surpassed, and yet only a paltry proportion of qual
The word “poison.” I am sorry to say there is a considerable amount of laxity in this particular, and it is quite within the range of possibility that, before long, you may hear of action being taken under the 17th section of the Pharmacy Act.

That section provides that it is unlawful to sell any poison unless it is distinctly labelled with the word poison, and the name and address of the seller attached. It is worthy of note that this applies to wholesale, as well as retail transactions. We have all need to be keenly on the alert concerning the sale of poisons. It should never be forgotten that it is the very essence of a chemist and druggist’s business from a legislative standpoint. It will be well to realize that except for that provision there would never have been any registration at all, much less anything approaching to legislative protection. It is undoubtedly our duty in the interests of the public, as it is distinctly in the interests of chemists themselves, that we should jealously maintain our rights and privileges in this respect with constancy and vigour.

To some extent my remarks this evening may be regarded as a sort of stewardship account, presented for your consideration and possible disapproval, but at any rate I have furnished you with sufficient subject matter to discuss.

Much of the Council business, indeed the greater portion of it, is purely routine in character, and sometimes, perhaps, a little monotonous; on the whole, however, the work is distinctly pleasant and interesting. There are, naturally enough, sometimes differences of opinion, but we are emphatically respectable. Courtesy invariably prevails, and never does the tone of debate degenerate to the level of modern parliamentary rhetoric, or town council oratory. As a new member, full of the mental crudity, which comes, I am told, of inexperience, I have good reason to be grateful for the kindness and forbearance always extended to me.

One of the subjects that occupied the attention of the Council at its last meeting was a note containing certain suggestions affecting the Manchester Scholarship, and, as you already know, it met with hearty approval. Surely the men of Lancashire and Cheshire will not imperil the existence of this Scholarship by further indifference as to its great value and usefulness. If eventually the Scholarship should be withdrawn and the fund devoted to some object or purpose where the kindness of the donor will be better appreciated, the apprentices of this district will have to bear the blame of their own unaccountable blindness and folly.

In conclusion, and in anticipation of your criticism, let me suggest that it serves no good purpose to rake up mistakes and omissions of a quarter of a century ago, unless, indeed, it be to take a lesson thereby. "Sufficient unto the day is the evil thereof." We live in the present and in the immediate future. There is work enough to do, and work enough for all, “though the labourers are few,” and I may say without presumption that the Council can be relied upon to discharge its legitimate share conscientiously and intelligently.

(The discussion on this address will be found at page 409.)
Pharmacy Act, 1868.

RECTIFICATION OF THE REGISTERS OF PHAR- 
MACHEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS.

We are requested by the Registrar to publish the following list of persons whose names will be erased from the Registers unless they communicate with him on or before December 30 next.

Those marked (x) are Pharmacetical Chemists.

Aberjona, Leonard Yates... 50, Road, Newcastle-under- 
Lyne
Ackerman, Henry......... 480, Commercial Road, Landport.
Addison, Robert......... 5, Oxford Place, Carle Road, Scar-
boroug
Agger, Joseph Edward.... 4, Eldon Street, Barkle
Ahkurst, William Edward... 53, How Street, Peckham, London, S.E.
Alexander, Adam Rankine... 52, Main Street, Newton, Ayr, N.B.
Allridge, William....... 83, Summer Lane, Birmingham.
Allridge, Wm. Edward... 41, Summer Lame, Birmingham.
Allen, George........ Patrhead, Dysart, Fife.
Allport, Henry Philipp..... 6, Snow Hill, Birmingham.
Allport, Samuel........ 6, Snow Hill, Birmingham.
Amery, John......... 10, Nevill Street, Southport.
Amphlett, Edmund....... 9, Mallard Street, Worcester.
Andrews, George James..... 8, Benwell Street, Woolwich, London, S.
Applebyard, Francis Henry... 76, Lambeth Road, London, S.E.
Bagshaw, Charles...... 9, Halford Road, Rochdale.
Ball, Edward......... Wallgate, Wigan.
Banks, Edward Edmund... 57, Fairbridge Street, Middle-
borough-on-Tees.
Barber, Daniel Stone..... 136, Alderney Street, Pimlico, London, S.W.
Barron, Henry........ 16, St. James's Road, London, N.
Barker, Charles Charles.... 76, Tumpmill Street, London, E.C.
Baron, Alexander....... 83, Market Street, Southport.
Bates, William......... 28, St. Andrew's Square, Huddersfield.
Bell, George........ 7, Townhead, Lockerbie, N.
Bell, Henry......... 8, High Street, Gosforth, New-
castle-on-Tyne.
Bell, William........ 13, Geneva Road, Seacombe, Che-
ster
Bellringer, Michael...... 25, Sheld Road, Newcastle-on-
Tyne.
Bence, Frederick Herbert... 14, The Beacon, Exmouth.
Bishop, Thomas......... 13, Bowers, Linlithgowshire.
Black, Charles Jeffery...... 4, Braid Place, Newton, Edin-
burgh.
Bladon, William George... 84, Blackmore House, Melvern Wils.
Bullock, Benjamin....... 8, Upper High Street, Winchester.
Bunce, Peter Gillard.... 18, The Bank, Bridge, Bordes-
ford Square, London, W.C.
Bowen, James.......... 44, The Road, Clapham, Lon-
dom, S.W.
Bowker, Samuel......... 86, Centre Market, Manchester.
Bowron, John........ 8, Brunswick Square, Greenwich.
Bradley, Edward......... 18, St. Ignatius Square, Preston.
Bradley, John........ 8, Wood Street, Spring Bank, Hull.
Breese, Thomas.......... 3, Cathedrak Close, Norwich.
Breath, Kenneth Benjamin... 41, St. Helen's Road, Swann.
Brett, Frederick John..... King Street, Leicester.
Brier, Ernest.......... 22, Newarke Street, Leicester.
Bromfield, John........ Honiton.
Brown, Angus Sinclair.... 67, Nelson Street, Great Grimsby.
Burtchett, Arthur Edward... 6, Wellington Street, Strand, Lon-
dom, S.E.
Bush, Arthur... 3, Birdcage Walk, Westminster.
Butler, Arthur Benjamin... 77, High Street, Croydon.
Butler, Henry James... 15, High Street, Burton-on-Trent.
Butler, James........... 29, Kent Parade, Heworth Road, ham.
Butterfield, Thomas Alex-
ander Carrode... 73, High Street, Sutton, Surrey.
Caldwell, John........ 4, Ellinwood Avenue, Belfast.
Carver, Frederick Paul...... Victoria Drug Hall, Montreal, Can.
Chisholm, Frank........ 70, Princes Road, Fairfield, Liver-
pool.
Chappelow, Thomas Henry... Seaford Cottage near Workop.
Clark, Alexander Gibson... 22, Miltisle Terrace, Edgbaston, Municipal, London, S.E.
Clark, Bernard Thomas... 2, High Street, Warrington.
*Clarke, Arthur Henry........ Wantage.
Codden, Alfred George..... The Infirmary, East Dulwich, Lond.
Coke, Richard Sweet...... 114, Fore Street, Devonport.
Cole, William.......... 203, Manchester Road, Bradford, Yorks.
Coley, William Henry..... 71, Beech Avenue, Shrewsbury, Shrew-
bury.
Coller, William, jun...... 70, South Street, Sheffield.
Collins, Richard Pugh..... 80, Well Street, South Hackey, London, N.
Colman, William.......... 45, Percyville, Chorlton-
Colledge, Manchester.
Cook, Robert........ 68, Silver Street, Highgate, Glasg.
Coote, Charles Samuel.... Longfield, Poole, Dorset.
Coxson, Joseph.......... 116, Bridge Street, Bradford, Yorks.
Cooper, John Henry....... 26, Marylebone Road, Lond.
Cooper, John Thornhill.. 62, Denmark Road, Greenvale, Man-
chester.
Coppock, Henry Jones..... 93, East Bridgeport, Dorset.
Corder, Ebenezer Porter... 2, East Terrace, West Ham, Lond.
Cotter, Cornelius........ 62, Culvert Road, Battersea, Lond., S.W.
Cox, Edmund George...... 244, Kennington Road, London, S.E.
Cragg, Thomas........ 2, Victoria Villas, Chesham Road, 
Tottenham.
Crocker, Thomas Bailey..... 6, Winterscroft, Croxen, Plymouth.
Crooke, Charles Gibbons.. 25, New Street Meeting, Bir-
ingham.
Crosland, George........ 111, Brierley Road, Stalisfield.
Curtis, Edmund........ 63, Argyle Square, London, S.W.
Cupler, Thomas........ 78, Stansfield House, Herts.
Davies, Thomas......... 82, Swanage, Dorset.
Davis, John Edward........ 50, Wigmere Street, London, S.
Davis, Bills Thomas........ 54, Culver Street, Battersea, 
London, S.W.
Davies, John Edward....... 47, Albert Edward Road, Liver-
pool.
Davies, Thomas Charles...... 29, Shenley Road, Camberwell, Lew-
eston, E.
Davis, William......... 54, Broad Street, Hereford.
Davis, Horace........ 3, Castle Road, Roath, Cardiff.
Deane, Edward William..... 21, Old Kent Road, London, S.E.
Day, Charles Estcourt..... 652, Old Kent Road, London, S.E.
Denton, Charles Hughes...... 1, Booth's Yard, St. James's, 
London, S.
Devereux, Arthur James..... Beaconsfield, Bucks.
Dixon, Franklin........ 13, Ferncliff, Mumbles.
Dodgen, William........ 5, Lower Street, Stockton-on-Te

*Downeswell, Jonathan... 1, Queen's Road, South Winc-
le, E.
Down, Edgar......... 80, Harleyford Road, London, S.
Draper, Arthur Longfellow... 10, Lorne Street, Leith, Edin-
burgh.
Draper, Henry Foulger..... High Street, Chippenden, Wilts.
Drummond, George........ Edinburgh.
Dods, John Westmacott... 50, Cannard Road, London, S.E.
Driver, William..., 8, 23, Oxford Street, Manchester.
Ellis, George Henry...... 99, North Road, Plymouth.
Ellis, William........ 4, Adderbury, Oxon.
Ellis, William........ 62, High Street, Birmingham.
Evans, Arthur Edward Sharp. 197, Tunney Park Road, Lea-
es, S.
Evans, David........ 79, Abbey Road, St. John's Wood, Lon-
don, N.W.

Prout, John, 17, Benson's Place Harrow Road, London, W.
Price, John Rhys ..... High Street, Chippenham, Wilt.
Price, Thomas Ulook ..... 81, Mallinson Road, Capham Junction, London, S.W.
Brotherton, Francis Richard Henry ..... Lydney, Gloucestershire.
Quarmby, Thomas William Leydan House, Welwyn.
Backham, George ..... Wenham's, Halsworth, Suffolk.
Raddcliffe, Robt & C. Cygill Abernaw Villa, Chestnut Road, Tonypandy.
Raddcliffe, E., Flick & Co., Australia.
*Rastrick, Robert Joseph ..... 57, Gloucester Street, Belgrave Road, London, S.W.
Richards, John ..... Mansfield, Marstonheath.
Richards, Richard Henry ..... 56, Albany Road, Camberwell, London, S.E.
Richardson, James ..... 57, Queen Street, Port Elizabeth, Cape Colour.
Ridley, Henry ..... 54, Northgate Street, Newcastle-upon-Tyne.
Ridley, Joseph Whittle ..... 152, Newgate Street, Newcastle-on-Tyne.
Rigby, James ..... 5, Mount Pleasant, Waterlow, Liverpool Pool.
*Riley, Charles Reynolds ..... Elm Tree Lodge, South Lambeth Road, London, S.W.
Ring, Edward James ..... 31, Springfield Road, St John's Wood, London, W.
Roberts, Anthony Tucker ..... 21, Buckingham Road, Brighton.
Roberts, Charles ..... Marsden, near Huddersfield.
Roberts, Robert ..... 185, Upper King Street, Liverpool.
Roberts, Thomas Anson ..... Conway, Carnarvonshire.
Robertson, Donald ..... Bervie, Kincardineshire.
Robertson, George Smith ..... Birrell.
Robert, James ..... 17, Dundas Street, Edinburgh.
Robertson, James Leigey ..... 129, Princess Street, Edinburgh.
Rowan, Robert ..... 19, Cardwell Street, Bolton.
*Rowell, J. J. (no go) ..... 241, Hyde Park Road, Headingly, Leeds.
Rowlett, Thomas Charles ..... 26, Barnby Street, West Ham, London, E.
Saffier, Thomas ..... 109, Bow Road, London, E.
Sanderier, James Boyce ..... 137, Dundonald, Glasgow, Scotland.
Sanderier, Thomas ..... 71, Parade, Birmingham.
Saull, William Benjamin ..... 7, Parade, Northampton.
Sclafadi, Samuel ..... 20, Eden Street, Oldham.
Sco t, Henry Fig ..... Woollen Pl, Provost Road, Dundee.
Scruggs, John Henderson ..... 16, Bristo Place, Edinburgh.
Seaton, William ..... 11, Mount Terrace, Edinburgh.
Seals, Robert ..... Charbury, Oxford.
Nee d, James Seller ..... 4, Braid Place, Edinburgh.
Sherlock, James ..... 207, Great Lear Street, Birmingham.
Simpson, Samuel ..... Fast Clock Town House, Goopert, Hants.
Street, George Beynon ..... Market Square, Buckingham.
Sarge, Thomas Date ..... 119, Long Acre, London, W.C.
Squier, J. P., Mortimer, Leicester.
*Saw, Walter Waller ..... 27, Union Street, Ryde, I. of W.
Smith, Andrew Less ..... 22, St. Leonard Street, Edinburgh.
Smillie, John ..... 4, Abbey Place, Glasgow.
Smith, Charles Alvert ..... Brook Street, Derby.
Smith, John ..... 65, Myrtle Street, Liverpool.
Smith, Peter ..... High Street, Buncorn, Carabtree.
Smith, Thomas ..... 3, Greenway Road, Corcoran Road, Bristol.
Snout, Charles Ickford ..... Ipswich.
Snares, John George ..... 11, Great Hampton Street, Brighton.
Solly, Stephen Francis ..... High Street, Dorking, Surrey.
Somers, Robert Walter ..... The Green, Mortlake, London, S.W.
Spencer, John ..... Elm Tree Cottage, Burton Pidsea, Hull.
Sponser, Robert ..... 185, Gooch Street, Birmingham.
Spenesly, Thomas Brentnall ..... 109, Whitehalles Road, Clifton, Bristol.
Spicer, Walter C. ..... 24, Pitfield St, Hoxton, London, N.
Speckley, George ..... 55, King Henry's Walk, Mildmay Park, London, N.
Stapleton, William Walker ..... Sheffield, Rds.
Steag, John ..... High Street, New Whittington, Derbyshire.
Stead, Thomas Albert ..... Farmby, New Southport.
*Steel, David ..... 25, Lothian Road, Edinburgh.
Steel, John ..... Bridge Street, Kilbirnie, Ayshire.
Stephenson, Archibald ..... 2, Portland Villas, Addlestone, Surrey.
Storey, Theophilus ..... 7, Pilgrim St, Newcastle-on-Tyne.
Street, Stephen ..... 14, Guilford Street, Russell Square, London, W.C.
Strawson, Vincent ..... 83, I-Linton, Liverpool.
Strickland, John ..... High Street, Peakon, London, S.E.
Stubbs, George ..... Darlington.
Stubbs, Tyson ..... 178, High Street, Deal, Kent.
Stuckey, William George ..... 83, Ladbroke grove Ed., London, W.
Sturges, William Thomas ..... 38, Shepherds Bush Green, London, W.
Swift, Charles Edward ..... Great Bridge, Staffordshire.
Talbot, Hugh ..... Esmcdon, Devon.
Talbot, Thomas Henry ..... 106, Finch Street, London, E.C.
Tye, John ..... 54, Watling Street, London, E.
Taylor, Joseph Walter ..... Boston, Mass., U.S.A.
Tyler, Arthur Berthe ..... 27, Meeting-House Lane, Fleetwood.

The Art of Prescribing.

The decline in the art of prescribing among medical practitioners of the present day has frequently been discussed at medical and pharmaceutical meetings. The general opinion seems to be that it is due chiefly to two causes—the abolition of the old system of apprenticeship in medicine, and the expansion of the medical curriculum in various directions to the exclusion of pharmacy and materia medica. The opportunity of gaining an intimate knowledge of drugs formerly afforded during the period of pupilage is now replaced by a course of about three months' instruction in pharmacy enforced in a more or less perfunctory manner. At the same time the principles which underlie the proper exhibition of medicines are almost entirely omitted from the course of medical education, it being assumed that sufficient opportunity of acquiring the necessary knowledge is afforded during the time spent in attending hospital practice. This opportunity is, however, reduced to a minimum by the custom of prescribing and dispensing from a hospital pharmacoepia or formulary, the object being to save the prescriber's time and economize labour in the dispensary.

Persons familiar with the administration of hospital pharmacy, and aware of the staff usually provided, will appreciate the difficulty of coping with the amount of work involved in dispensing medicines for hundreds of patients daily. In the larger general hospitals three hundred or more out-patients will be sent to the dispensary from the various consulting rooms during a period of about three hours: it is obvious that four or five dispensers would be unable to accomplish the work in the time available under such conditions as obtain in an ordinary pharmacy. The hospital pharmacoepia, therefore, may serve a useful purpose in accelerating the serving of patients, by providing formulae for the exhibition of certain more or less routine remedies for common ailments. The prescriber simply writes the name of the preparation, e.g., mist. quin. cum ferro, and states the dose; the dispenser then supplies the patient with the required quantity from a bulk previously prepared according to the formula in the hospital pharmacoepia. The prescriber also saves the time required for writing out the prescription in full, but this acts greatly to the detriment of medical education in prescribing. The students attending hospital practice see various mixtures, pills, etc., ordered merely by name, and frequently know neither the ingredients, doses, nor the means adopted to combine the constituents into a presentable form. To this want of knowledge many observers attribute the increasing use of nostrums and ready-made preparations in medical practice, and from this point of view the hospital pharmacoepia does considerable harm. If it be used too freely the medical student sees little or no real prescribing, and this deficiency in his education oppresses him throughout his after career as a medical practitioner.

The abolition of the hospital pharmacoepia altogether would no doubt do much to promote a better state of affairs, but this would necessitate the increase of the dispensary staff to such an extent that the hospital authorities would hesitate to sanction the change, involving, as it would, a considerable increase of expenditure. If the hospital authorities could be induced to face the increased cost of dispensary administration, it would be better for medical education that the prescribing and dispensing in our general hospitals should be rendered altogether independent of the use of the ready-made medicine, for which formulae are given in hospital pharmacoepias. It may be maintained by some, however, that the hospital pharmacoepia, if embracing only the commonest remedies and therefore limited in size, may serve its purpose without, at the same time, crippling the teaching of prescribing in the hospital. Certainly, in hospitals for special diseases, which are usually attended only by qualified medical men, less harm is done by the use of a so-called hospital pharmacoepia, and the special form of medication required better justifies the use of medicine prepared according to specially constructed formulae.

The Art of Prescribing.

THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

SaturDAYS, NOVEMBER 17, 1894.

THE PHARMACEUTICAL JOURNAL.

FIFTY-FOURTH YEAR OF PUBLICATION.

EDITORIAL DEPARTMENT.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

ADVERTISEMENT DEPARTMENT.

Advertisements and remittances must be sent to "Street Brothers," 5, Serle Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased. Cheques and money orders must be made payable to "Street Brothers."

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Brookes, 17, Bloomsbury Square, London, W.C.

Further details, regarding the remuneration of correspondents, may be obtained of the Secretary.

PHARMACEUTICAL MEETINGS.

Secretaries of pharmaceutical associations throughout Great Britain are requested to send early intimation of any meetings to be held in their respective districts, for publication in the "Diary of the Week." To ensure prompt attention all notices and reports should be received not later than Wednesday morning in each week.
PROFESSOR GREEN'S LECTURE.

The lecture, delivered by Professor Green on Wednesday evening, a verbatim report of which will be published in next week's Journal, opened with a definition of a nervous system, which was shown in its simplest form to be the means possessed by an organism either of originating movements, &c., by changes in its living substance without any external cause, or of receiving impressions from without and responding in some way to those impressions. A distinction was further drawn between the actual response and the transmission of molecular disturbance leading to it, or, in other words, between nervous and muscular or other visible mechanism. The nervous system essentially consists of three parts: one concerned in the communication to the organism of influences from without, the so-called afferent or sensory mechanism; one concerned in the production of the various efforts of the body, the efferent or motor nervous tracts; and a central one originating the latter, or co-ordinating this with the former. One of the simplest animals, Amoeba, and one of the simplest plants, Aethalium, were then compared and shown to have very similar arrangements in this respect. The chief importance of a nervous system was pointed out to be the placing of the organism possessing it in harmony with its environment, and enabling it to adopt itself to changes in the latter. The environment of the plant was briefly described, and its advantages and dangers sketched. The general sensitiveness of the plant was then discussed and illustrated, and its power of responding to external stimulation shown to depend on a certain condition known as "phototonus," which is easily disturbed, with serious results.

The question of the special sensitiveness of plants to particular forms of disturbance or stimulation was then examined in some detail. The susceptibility which plants possess was shown to be most easily manifested by movements of growing organs, though it is also seen in some adult ones, by movements, secretion, &c. By a series of instances it was shown that varying powers of appreciating light gave the impression of a rudimentary vision. The localisation of the power, and the nature of its manifestation were then examined, and the extreme sensitiveness of some plants pointed out. Similar powers of response to other forms of stimulus were then discussed, and various plants shown in different ways to possess of rudimentary powers of touch, taste, smell, and muscular sense, or sense of equilibrium. A rudimentary power of reflex action was claimed by Darwin for certain tentacles of Drosera. This was discussed and illustrated.

ALKALOIDS OF IPESCUANUA.

At the evening meeting on Wednesday, Dr. Paul exhibited a number of specimens prepared during the course of his work on the chemistry of ipescuanua. These included emetine hydrochloride crystallised from dilute hydrochloric acid and water respectively, cephaline hydrochloride crystallised from weak hydrochloric acid, and several other exhibits illustrating the very different solubility of emetine and cephaline in water and petroleum spirit.

CHEMISTS' BALL.

A MEETING was held at 17, Bloomsbury Square, on the 5th inst., to make arrangements for the forthcoming ball. The following were elected to form the committee:—Mr. M. Cardew, Chairman; Professor John Attfield, Treasurer; Mr. A. J. Phillips, Hon. Sec., 156, Cromwell Road, S.W., with Messrs. Bowen, Bremlidge, T. H. Francis, T. C. W. Martin, J. H. Mathews, A. J. Merrell, A. C. Preston, J. Style, and John C. Unnry. It was decided to hold the ball at the Portman Rooms, on Wednesday, January 16, 1889, and circulars have been issued inviting gentlemen to act as stewards. Any who have not replied and may be desirous of having their names on the stewards' list will oblige the Honorary Secretary by communicating with him as soon as possible.

INVENTION OF LUCIFER MATCHES.

A MOVEMENT is on foot to erect a statue at Stockton-on-Tees to the inventor of lucifer matches, John Walker, a druggist in that town, who died in 1887. As mentioned in an article in the Pharmaceutical Journal, by Mr. Barnard S. Proctor ([3], ii., p. 41), Walker supplied prepared matches which were ignited by being drawn between the folds of a piece of sandpaper. The matches consisted of thin slips of wood about 2½ inches long, and the thickness of cardboard, dipped in a composition containing antimony sulphide and potassium chlorate. They were sold in boxes of fifty with a piece of sandpaper, at the price of one shilling per box.

THE PHARMACOPEIA AS A STANDARD.

Not the least important point in Mr. Bow's address to the Edinburgh District Chemists' Trade Association is his reference to the growing tendency to substitute for pharmacopoeial preparations supposed "improvements" on these. The main object of having a national pharmacopoeia is undoubtedly to secure uniformity in medicinal preparations, so that wherever a prescription is dispensed the product may be the same, and, whether or not a modified formula or process yields an improved article, pharmacists are not justified in adopting the modification generally unless, and until, it receives official sanction. Whilst there is every reason for endeavouring to ascertain methods by which better preparations may be obtained, there is no legitimate ground for ignoring the Pharmacopoeia in respect of what it renders official.
RECORDS OF THE REGISTER.

Under the Pharmacy Act of 1868, section x, the Registrar is authorised to keep a correct register of chemists and druggists, and to this end is empowered to erase the names of all registered persons who shall have died, and from time to time to make the necessary alterations in the addresses of persons registered under the Act. If, after the Registrar has sent two registered letters to any such person at an interval of six months, no reply be received, within three months of the date of the second letter it is lawful for him to erase that person's name from the Register. In the case of the individuals whose names are published in the list on pages 398-400 of the present issue of the Journal no replies have been received to the registered letters sent, and unless they communicate with the Registrar on or before December 31 next, their names will be erased from the Register accordingly. Divisional and local secretaries, and friends of the persons mentioned, are requested to assist in making the Register as accurate and complete as possible by attracting the attention of interested parties to the list, or furnishing such information regarding them as may be in their power to the Registrar, 17, Bloomsbury Square, London, W.C.

FORTUNES LEFT BY DOCTORS.

Under this heading the Daily Telegraph of Tuesday last gives some interesting statistics regarding the amount of personally left by medical practitioners within recent years. Sir William Withney Gull, who is said to have admitted that he had made over £13,000 in one year, left £344,492 in personally; Dr. Thomas Rhodes Armitage, £217,420; Sir Andrew Clark, £203,970; Sir Oscar Moore Pavy Clayton, £147,746; Dr. Lawrence Trent Cumberbatch and Dr. George Dixon Longstaffe, each £107,000; whilst fifty-five other medical men, who have died within the past five years, left sums varying from £88,401 to £240, only five being below £10,000.

ROYAL SOCIETY ELECTIONS.

The list of those recommended by the President and Council of the Royal Society for election into the Council for the year 1895, at the anniversary meeting on November 30, is as follows:—President, Lord Kelvin; treasurer, Sir John Evans; secretaries, Professor Michael Foster and Lord Rayleigh; foreign secretary, Sir Joseph Lister; other members of the Council, Dr. Commons, Professor Crookes, Professor Darwin, Professor Forbes, Sir Douglas Galton, Professor Alexander Henry Green, Sir John Kirk, K.C.B., Professor Horace Lamb, Professor Edwin Ray Lankester, Professor Alexander Macalister, Professor John Henry Poynting, Professor Arthur William Rucker, Mr. Osbert Salvin, Professor Burdon Sanderson, Professor Thorpe, and William Henry White, C.B.

MISCELLANEOUS NOTES.

The Copley medal of the Royal Society has this year been awarded to Dr. Edward Frankland for his valuable chemical researches; the Rumford medal to Professor Dewar, for his work on low temperatures; the Davy medal to Professor Cleve, of Upsala, for researches into the chemistry of rare earths; and the Darwin medal to Professor Huxley. The Royal medals have been conferred upon Professor J. J. Thomson, for electrical work, and Mr. Victor Horsley, for his important investigations relating to the physiology of the nervous system and of the thyroid gland.

Louis Figuier, whose death is just reported from Paris, is best known for his popular works on science, his "World before the Deluge" being perhaps the most celebrated. He was a chemist by profession, but devoted himself mainly to the literary labours which have done so much to popularise science among the young.

The annual dinner of the Western Chemists' Association of London will be held at the Café Royal, Regent Street, W., on Wednesday evening, November 21, near Messrs. B. J. and J. J. Jackson (6s. 6d. each) for themselves and friends from the Hon. Treasurer, Mr. J. H. Mathews, 68, Queen's Gardens, W., or from either of the Hon. Secretaries.

Pharmacists have been elected to the mayoral chair for the ensuing year at Beeches (E. Watson), Grimsey (Ald. Enoch Palmer), Haverfordwest (W. Williams), Lampeter (R. Evans), Margate (Ald. E. S. Wootton), Pembroke (J. H. Bowline), and Shrewsbury (Ald. W. Gwern Cross), while at Droitwich, Stephen Harris, chemist and druggist, headed the poll at the municipal election. Mr. Cross, as is well known, is Vice-President of the Pharmaceutical Society, Mr. Palmer is a member, and Messrs. Bowline and Harris are associates.

The Scottish municipal returns include the names of the following pharmacists, who have been elected to the town councils of their respective burghs:—William Park, Broughty Ferry, an investigator local secretary, for Dundee; James Bisnett, Burntisland; William Dog, Dundee; David Gilmour, Dunfermline. Messrs. Park and Gilmour are members of the Pharmaceutical Society, and Mr. Bisnett is an associate.

Messrs. Park, Davis and Co., of North Audley Street, W., desire to disclaim any connection, direct or indirect, with certain wholesale and retail establishments carried on under somewhat similar titles.

At the recent graduation ceremony of the University of Edinburgh, John Penny, M.B., C.M. Edin., of Great Broughton vid Carlisle, an associate of the Pharmaceutical Society, was the only recipient of the B.Sc. degree in the department of public health.

We learn from the Leeds Mercury that a work entitled 'Fifty years of Pharmacy' is in course of preparation by Mr. T. G. Forschaw, the author of the Pharmacopoeia of the Bradford Infirmary and Dispensary, and the late dispenser in that institution. One of the chapters will be devoted to a consideration of "the rise and fall of stamped medicines."
Transactions of the Pharmaceutical Society of Great Britain.

DONATIONS.

At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 14th inst., the Librarian and Curator presented the following report of donations to the Society's Libraries and Museum:

To the Library in London:
University College, London:
Calendar, 1894.

University College, Nottingham:
Calendar, 1894.

Royal College of Surgeons of England:
Calendar, 1894.

City of London College:
Calendar, 1894.

Mason College, Birmingham:
Calendar, 1894.

St. Bartholomew's Hospital, London:
Statistical tables of patients for 1893.

Smithsonian Institution, Washington:
Annual report for 1892.

School of Pharmacy Students' Association:

Government Printing Office, Perak:
Perak Museum Notes, No. 3, by L. Wray, jun.

Mr. Joseph Ince, London:
Quincy's Dispensatory, 1718.

Professor Dr. E. C. Flagg, Groeningen:
Ueber die Identität von Sophorin und Cytisin.

Mr. J. R. Gero, Strassburg, Neudorf:
Ueber Gauktherin, ein neues Glykosid aus Betula lenta, 1894.

To the Library in Edinburgh:

School of Medicine, Edinburgh:
Official Calendar, 1894.

To the Museum in London:

Professor J. F. van Zeden, Colonial Museum, Haarlem:
Fourteen specimens of barks from Surinam; Coca leaves from Erythroxylon bolivianum and E. apricozum cultivated in Java; the leaves of Orthosiphon stamineus, Feronia aurantifolia and Croton flavens, and the fat of a species of Myriophyllum from Borneo.

Mr. G. H. Hawtayne, Administrator-General, British Guiana:
Fruit and leaves of the Tonka bean of British Guiana.

Dr. E. Treesor Collins, London, through Mr. W. Martindale:
Specimens of an Asecectida plant and of the gum resins Opopanax, Galbanum, and Sagapenaum, recently brought by him from Persia.

Dr. J. E. T. Atchison, Cashmir:
Ripe fruits of Feraula nardes from Astore.

To the Herbarium:

Mr. D. Mitchell, Inverness:
Specimens of Arostostaphylos wax-wax, in fruit, and of Lycoceum coccinacum.

The Curator:
Specimens of Anagallis arvensis, with the leaves in whorls of three and four, from Torquay.

Proceedings of Societies in London.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held on Thursday, November 8th, the President, Mr. R. H. Jones in the chair. After the usual formal business had been transacted, a paper was read on "Sneezing," by Dr. Soanes Spicer. The author divided his paper into three sections, (1), a brief account of its references to sneezing by ancient writers, including various traditions attaching thereto; (2), "sneezing's health," with especial reference to its causes and mechanism; (3), "sneezing in disease," such as excessive sneezing—the causes and treatment. Thus of sneezing has always been regarded as supernatural, and by many races—Greeks, Romans, Maries, etc.—was regarded as a good omen, and as such, held in reverence. Hence arose the custom, not even now altogether obsolete, of making some remark dexter after sneezing. We are told by ancient writers that sneezing was regarded as a sign of impending death during the plague of Athens. Very many classic writers make especial reference to sneezing, and are supposed that during sneezing devils were expelled. Sneezing itself is a reflex nervous action, and brought about by mechanical irritation to the ends of the nerve fibres which occur in the tissues of the nose. When this irritation occurs, whether it be due to a foreign body or change of temperature affecting the tissue of the nose, a nerve impulse is transmitted to the brain and certain nerve centres in the spinal cord, and the result is an impulse being transmitted along the nerves to the muscles controlling respiration. By this means the egress of air during expiration is delayed, and the various exits are closed. When the pressure, however, reaches a limit, the exits are forced open, a powerful blast of air is expelled, and the person sneezes. Sir Morley MacKenzie supposed that the effect of this was to expel any irritating particles from the nasal membranes by it is more probable that certain changes in the blood supply cause a secretion of mucus, which washes away the offending particle. Sneezing may be checked by concentrating the attention on something else, or by firmly compressing the nostrils. When excessive it demands serious attention, and the causes may be referred to certain morbid conditions.

The author concluded his paper by describing a number of instruments used in nasal surgery. These were placed on the table and included various shape, an electric cautery, and a saw driven by an electric motor.

The President remarked that running very often seemed to cause sneezing, and, referring to the cocaine habit, stated that prescriptions ordering cocaine should not, in his opinion, be repeated ad libitum.

Mr. Lloyd Williams, L. Rogers, Tickie, and other members joined in a discussion which followed the reading of the paper, several members raising their idiosyncrasies with regard to sneezing.

Dr. Spicer, in reply, stated that a branch of the nerve that reached the nasal membranes passed the conjunctiva, and the stimulus of light to this branch was carried to the brain, which did not differentiate between the irritation to the nose and stimulus of light to the nerve ending in the eye. It was of the opinion that certain drugs should not be repeated unless the prescription was initiated, it suggested that a list of such drugs might be made.

The cocaine habit was responsible for numbers of lunatics, since it rapidly caused degeneration of the brain.

A vote of thanks to Dr. Spicer was proposed by F. A. Rogers, seconded by G. Roe, and carried with acclamation, after which the meeting terminated.
Scottish Transactions.

EDINBURGH DISTRICT CHEMISTS' TRADE ASSOCIATION.

The opening meeting of the session was held in the Pharmaceutical Society's House, 36, York Place, Edinburgh, on Thursday, 8th inst., at 11 a.m., Mr. Peter Boa, President, in the chair.

There was a good attendance, and apologies were intimated from Messrs. R. Atikin, Macpherson, Nelson, and F. Stephenson.

The last meeting having been read and approved, the following new members were elected: Messrs. John Brown, W. Manson, A. K. Stewart, W. Swan, T. Thompson, and A. Watt, Edinburgh; and J. McLaughan, Grangemouth.

Mr. C. F. Henry, secretary, read the text of an application to the Board of Inland Revenue for permission to use proper names in the possession of labels for such medicines as "Dr. Gregory's Pills" and "Easton's Syrup," without the necessity of affixing medicine stamps to the packages containing the medicines. He also read the correspondence on the subject with the Glasgow, Dundee, Aberdeen, and Dumfries Associations, and the transactions with the other associations agreed to sign the application. The Glasgow Association suggested that the points in dispute should be demanded as a right rather than as merely a concession.

In reply to the application the Board of Inland Revenue declined to make the desired concession, but expressed willingness to grant the same indulgence to the preparations referred to as allowed in the case of "Bland's Pills," and other well-known pills, under the conditions published in the Pharmaceutical Journal of November 12, 1887 (p. 401). By an alteration in the arrangement the Trade Association in the case laid down, the object of the application would be practically attained. To obviate the practical difficulty of specifying all the ingredients on labels for small boxes, the Board, in a further communication, agreed to grant permission for the name of the pills or other of the medicines in question to be printed after the word "pills"—for example, Pills (Gregory)—thus avoiding the use of the possessive case.

The Secretary further reported that he had communicated the final reply of the Board of Inland Revenue to the other associations interested, and had received from many one whose wish was for the matter to be taken in further action, but believing that the matter might now be allowed to stand on the footing indicated in the second letter from the Board.

Mr. Wylie said he thought they should raise a guarantee fund and have a test case tried. He felt sure the courts would condemn the view insisted upon by the Board.

A discussion took place, taken part in by Messrs. Bowman, Glass, MacKenzie, and D. McLaughan, and it was moved by Mr. MacLaren, and seconded by Mr. Noble, that no further action be taken, but that the matter be referred to the Board be accepted.

Mr. Wylie moved that the other associations be asked to join in a test case, but this motion was not seconded, and the motion of Mr. MacLaren was declared carried.

Mr. MacLaren, as Convenor of the Chemists' Ball Committee, reported that at the last meeting it was decided to ask for a donation of £100 to the Drumsill Roll of the Association. The ball was now in its twelfth year, and the balance at present was about £20. It was thought better to put the matter in the hands of the Association, rather than, as hitherto, have a shifting and uncertain Committee. In the meantime, he suggested that the Association appoint three gentlemen to act along with the Ball Committee.

This was agreed to, and the President (Mr. Boa), the Vice-President (Mr. Bowman) and the Secretary (Mr. Henry), were appointed.

The following address was then delivered by the President:

OPENING ADDRESS
BY PETER BOA.

In the honourable position in which your kindness has placed me as Chairman of this Association, I desire to take advantage of the opening of the opening meeting for the session to say a few words in regard to our Association and other matters which seem to me to be worthy of consideration. Let me say at the outset that I am greatly gratified by the continued success of our Association. My earnest hope is that it may go on in prosperity and usefulness. Even in the short period of its existence it has been the means of bringing together and making better acquainted members of the retail trade within the scope of its operations. Our meetings have been favourably attended by good attendances, and that so many have made their arrangements to be present shows that things went well in this respect for this season. Until the advent of our Association, the facilities for intercourse among members of the trade in our district were not complete. We had the evening meetings of the Pharmaceutical Society, where scientific matters were discussed and opportunity was offered abundantly for friendly chat in the tea-room. These meetings have not, however, been attended as I confess I should like to see them attended. Some members of the trade are not, perhaps, deeply interested in the subjects, others may not subscribe to the Society and do not feel at home in the Society's rooms. The ball that we have been here and there are not all dancing men there were always some to whom that function did not appeal. Now the requirements of those who are not enamoured of science or dancing are met by our Association. We are all interested in trade. Anyone who attends the evening meetings of the Pharmaceutical Society, the ball, and the meetings of our Association has a good chance to be on terms of personal acquaintance with every member of the trade in the district. We can scarcely expect many to be in this position. Men are different tastes. I cannot, however, think that there is only one whose wish is to take part in any further action, but believing that the matter might now be allowed to stand on the footing indicated in the second letter from the Board.

Mr. Wylie said he thought they should raise a guarantee fund and have a test case tried. He felt sure the courts would condemn the view insisted upon by the Board.

A discussion took place, taken part in by Messrs. Bowman, Glass, MacKenzie, and D. McLaughan, and it was moved by Mr. MacLaren, and seconded by Mr. Noble, that no further action be taken, but that the matter be referred to the Board be accepted.

Mr. Wylie moved that the other associations be asked to join in a test case, but this motion was not seconded, and the motion of Mr. MacLaren was declared carried.

Mr. MacLaren, as Convenor of the Chemists' Ball Committee, reported that at the last meeting it was decided to ask for a donation of £100 to the Drumsill Roll of the Association. The ball was now in its twelfth year, and the balance at present was about £20. It was thought better to put the matter in the hands of the Association, rather than, as hitherto, have a shifting and uncertain Committee. In the meantime, he
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS.

[November 12, 181]

the correspondence which our Association, in conjunction with the other Scottish associations, has had with the Inland Revenue in regard to certain well-known medicines. I am sorry that the Board of Inland Revenue has not seen its way to grant the correction of the error which that medica bearing the name of the originator, which are not sold as proprietary medicines and the formula for which are published in standard books relating to medicine, should be allowed to be designated in the possessive case without such designation rendering them when sold as stamps for the purpose. As examples, I may mention Easton's syrup and Christer's pills. The Board has granted this concession in the case of Gregory's powder, "as much as it was never sold as a nostrum." It was pointed out that Christer's pills and Easton's syrup were never sold as nostrums, and logically should be treated in the same way as Gregory's powder, but the Board declined to concede the point. So far as I have been able to gain information on the subject, the Board originally declared such medicines liable for want of proper information as to their character, and as no one has, by reference to the law courts, obtained in the fullness of the fallacious course of the case, a proof that it has "bluffed" and adhered to its original decision. From time to time it declares a preparation of the nature of fluid magnesia to be liable to duty. In such an instance, a reference to the "Pyreto Salbo" case invariably leads to the Board revising its decision.

I am very pleased to see that the revenue derived from the sale of medicine stamps has declined so materially. Let me hope that a still further decline will be indicated when the next returns are published. The sale of proprietary medicines advertised to cure all ailments is highly derogatory to legitimate pharmacy. Unfortunately, pharmacists were the original media of their distribution to the public, and as the medicines yielded a fair profit their sale was tolerated, and may have in some cases been encouraged. We can scarcely grumble now if, when we want to rid ourselves of them and their advertisements, we cannot do so easily as we should like. The cases which have been in the law courts in connection with the sale of stamped medicines containing poison have put the public on the alert in regard to all medicines sold under a Government stamp. It is noticeable that many more inquiries are made in regard to templating their purchase. They ask if they are safe, if they are not "just rubbish," if the advertisements in regard to them are to be entirely, partially, or not at all believed. Up till a few months ago the purchase of stamped medicines was so much a matter of custom with the public that they went on buying without thinking much, if at all, about it. Now that they have begun to look into the matter, they are not so wanting in sense as not to perceive that they may have been not only spending their money foolishly, but exposing themselves to unknown danger. When they read, in their awakened condition, some of the advertisements of these medicines, I am not surprised that they ask their pharmacist for advice before making a purchase. To see an article advertised as suited either for internal or external use, to cure rheumatism, headache, cold in the head, hemorrhoids, spasms, and diarrhoea, as well as being a universal cure for all ailments, I should think enough to make even an exceptionally confiding person suspicious. In many cases where inquiry is made, the opinion of the pharmacist decides the point as to whether the article in question is purchased. It is only reasonable that the word of an educated pharmacist of known reputation should be accepted in preference to the obviously inflated statements of an unknown nostrum-monger.

The decision of the Board of Inland Revenue to apply the Stamp Act to homoeopathic medicines I consider, right. If an allopathic chemist be allowed to require retention of account of acorns for freeness, I confess I cannot see why a homoeopathic shoemaker should not be required to state the nature of sulphur," exemption might be claimed if it were frankly stated on the label that the "preparation" was only proof spirit.

The sale of proprietary articles has been lately taken up by drug stores owned by unqualified persons who have been engaged in the business at all until they formed a "limited" company in order to trade in drugs. A draper or tanner, accustomed to deal in ready-made articles, has naturally to ready-made medicines, and his trade on purely trade lines fits him to negotiate the purchase and sale of these ready-made things.

The qualified assistant whom he is obliged to employ knows something of drugs and galenical processes, and by his means the quodam draper is enabled to engage in all the procedure of a pharmacy. He then advertises that he dispenses prescriptions, all half chemists, and where he finds that his knowledge thereof it is possible to be implied that he is not a chemist. Few of the public would notice it. He has no scruples about the notions of professional dignity, and he advertises in a drapery-fancy dress style, to which few pharmacists of decent taste can bring themselves. Company pharmacy, sort will go on so long as qualified assistants can be found to take service under unqualified employers. At the present moment there appears to be an inclination on the part of young men to enter such service. They get better salaries, they say, and shorter hours. That is so in many cases, I admit. If they decide to be always assistants, I have nothing to say against their procedure. But if they have an intention of going into business on their own account, I wonder if they expect that the objectionable state of things which they have assisted to create and are now present assisting to maintain will disappear just because they decide to open a pharmacy. It will, I fear, be a long time before the present condition of affairs will be altered. Probably the manner in which alteration will be effected will be the condition under which entrance to the calling of a pharmacist can be made. At present the conditions are raised as by the old personage. An assistant becomes a partner by sticking close to his employer until he goes to business, or he may not. It is purely a matter for his own consideration, unless his employer have some conscientious scruples. He may be allowed time to attend classes, or he may not. His duties first may consist largely of taking out parcels ordered up, or they may be such as to initiate him into the essential operations of pharmacy.

In preparation for the second and qualifying examination he may study at a school or he may stay at home; he may indeed not study at all, but shut to cram. There is not a uniform method of preparation for the examination which some of the young men of the practice of pharmacy. When the conditions of entrance to pharmacy are so wanting in uniformity, can we wonder at the want of unanimity and kind interest which exists among those engaged in it? Looking at the matter from a business point of view, I feel an inclination that some alteration is desirable in the system of taking apprentices who have been customary here. We have been taking for a varying term of years, paying them a grossly salary and giving them certain duties to perform. In many instances the performance of these duties is of very great good for the salary and initiation into the ways of business. It saved the employment of that labour, which would likely have been more expensive.
Possibly the percolated extract will be the better of the two, but it is not the official standard. Let us by all means endeavour to ascertain the method by which we can get the best preparation. If we discover an improvement on an official process the Pharmacopoeia Committee will no doubt make a note of it, but until they sanction its use we had better keep it out of practice, unless we want to create misgivings in the minds of prescribers and patients, and give trouble to our fellow-chemists. Our Pharmacopoeia has a few faults; they are, however, minor ones. It has the confidence of the best prescribers. One of these remarked to me the other day that he sometimes prescribed a novelty to please patients, but he always cured them with the Pharmacopoeia. Preparations sold as pharmacopoeial should, I maintain, be made according to the official processes.

The Vice-President, Mr. Bowman, said, owing to the limited time, he would suggest that any discussion of points raised in his paper was left till next meeting. He then moved a hearty vote of thanks to the President, which was awarded with acclamation. The President returned thanks, and the meeting then closed.

Provincial Transactions.

MIDLAND PHARMACEUTICAL ASSOCIATION.

A meeting of this Association was held at the Man College on Thursday evening, November 8, Mr. R. D. Gibbs, President, in the chair. The minutes of the meeting were read, of which the following is an abstract:

TINCTURES AND TINCTURE MAKING.

BY H. W. JONES.

The pharmacopoeial tinctures are made by several methods, the bulk being produced by a combination of maceration, percolation, and pressure. By these means it was intended to fully exhaust the drugs, and present the soluble constituents in a definite volume of liquid. The purpose was answered, but with more care and more care working than necessary. In the original edition of the 1885 Pharmacopoeia, tinct. singib. fort. was directed to be prepared by percolation, but in the "Additions" subsequently published, three others were ordered to be so made. The general instructions for tinct. hamamelis, and tinct. hydrastis were perfect, and it was to be taken into the form of the times that the new method was recognised. That the bulk of the tinctures of the Pharmacopoeia could be so prepared was not to be contended. The three essential points to be attended to were, (1) to damp as quickly as possible to avoid loss, and to store in a closed vessel during maceration; (2) to prevent the moistened ingredients so as to avoid airs spaces; and (3) to keep the surface just covered with the menstruum during the entire process. Some operators packed straightway into the percolator after damping, but in most cases at least, the author found it advisable to store for twenty-four hours in a separate vessel, and then mix the vessel, and finally mix well together, adding a little more menstruum if really necessary before the final packing. The percolator was generally advised to be of a conical shape, but operating on a large scale, with a considerable amount of material, a vessel of that form had the disadvantage of giving a large surface to the lower layer of spirit, and consequent liability to loss from evaporation. Whatever form of percolator was adopted it was a distinct advantage to have the bottom part of it tapering.

For the author's own part he preferred a tap, which could be closed or opened, to a simple tube; and
showed a model of a percolator which he had devised. This consisted of an upright, somewhat narrow metallic vessel, with a funnel-shaped bottom part, provided with having a thin metal sheet, so that tubes of various lengths could be screwed on or off, the special feature of the percolator being a band of metal around the bottom part, deep enough to enclose the tap when the tubes were removed. By means of the band the apparatus would stand erect on any plane surface. It was used as a percolator with ointments, on a stout bench, with diamond-shaped holes, through which the band could be passed, to turn on or off the taps, or fix the tubes. In commenting on various tinctures it was considered that with tinct. camp. co. the opium might advantage be rendered more active by a corresponding amount of tinct. opii, as advocated by Squire. In the case of tinct. cardam. co. the author said he would venture to suggest that the variety of raisins known as "sultanas" might be used, as they contained no tinct. which could be prepared by percolation if the various ingredients were well mixed together.

It had been suggested to prepare tinct. coccicinii by means of a weaker spirit, but Groves found that even with proof spirit it was nothing like so good as when the spirit was slightly stronger. Tinct. guaiaci ammon. would be better prepared with a stronger menstrum, Wright's proportions of 18 oz. S.V.R. and 2 oz. liq. ammon. fort. giving 82 grains per oz. of solids as against 62 grains for the present spirit of ammonia. Tinct. myrrhae was an example of a tincture which could not be prepared by percolation without previous maceration. Tinct. podophylli should not be fluorescent. The author had recently seen a tincture which was strongly so; and he had pointed out some years ago that that result was due to the employment of resin precipitated in alum water instead of the B.P. method. Heat was unnecessary in making tinct. quininae, and the suggestion of Lunan as to the substitution of carbonate of ammonia for the hydrate was worthy of the attention of the pharmaceutical authorities, since the product formed a clear solution with 13 parts of distilled water, whereas the present tincture required 20 parts.

The final tincture was to contain a decided amount of spirit. By pressure a certain proportion could be obtained, but a relatively large quantity was left behind. He had found, for example, that a batch of 60 gals. of tinct. opii would leave something like 2 gals. in the mor. and a similar amount of spirit. In the case of tinct. cinchon. co. tinct. hyoscyami, and tinct. sennae, respectively. In no case was it desirable to wash out that spirit with water, if it were intended to form part of the finished product. On the whole, he preferred to percolate right through with the proper menstrum till the full bulk was obtained, and to recover the spirit from the mor. by distillation in a large still with sufficient water to prevent the formation of clots of material. To wash certain moras with water took considerable time, during which the mass was apt to become mouldy or decomposed.

In reference to standardised tinctures there was a desire on the part of the alkaoldal strength of both tinct. opii and tinct. nucl. viscosa in the Pharmaco. Experience had shown that the menstrum did not extract the opium, but by taking a tincture made with a strong opium, and one made with the B.P. drug, the percentage required could be obtained by means of the percentage indicated by an essay. As to the method of assaying tinct. opii, he would prefer to follow the B.P. method as closely as possible rather than attempt washing out with acetic ether and chloroform. Familiarity with tinct. nucl. viscosa had not strengthened the view that the use of extract was the best method of preparing it. Similarly the employment of extracts of other drugs was not to be advocated that it was truly a percolation process which received particular attention at the 1833 meeting of the British Pharmaceutical Conference and had been condemned. A tincture was supposed to contain the constituents of the drug as they existed in the drug themselves, unaltered by heat. Gerrard's statement had not been contradicted that all the phosphate solution had been lost in alcohol even for ten minutes lost 50 per cent of its alkaloidal constituents. At present there was no direct authority for standardising generally, but there was a demand for standardised preparations; and the result was that in the absence of official methods and wholesale homoeopathic pharmacists was left to the standards, so that uniformity was not likely to exist. Something was wanted more than mere statements of percentages; the methods of analysis should be well defined.

Mayer's solution was out of date, and it was badly settled whether volumetric methods or gravimetric processes should be followed, or even in some cases as that of aconite, if the test should not be physiological. Missers. Wright and Farr stood pre-eminent amongst British workers, and had for years been publishing the most important results, and they thought their methods of assay might well be adopted. Standards had been suggested, in many cases of strong good drugs, but the author of the paper had met with a practical difficulty which required some construction. It was, that it was not difficult frequently to define drugs above average that might be found, and the question arose, should we undertake a preparation of a "average" strength? He thought that as the pharmacopoeia distinctly ordered a definite weight to be taken, so that for the present at least he ventured to suggest that the standard should be that approximating to the highest percentage. Concentrated tinctures might receive some attention at their hands. They were more properly described as fluid extracts, and experience had shown that such extracts, prepared with proof spirit at least, were somewhat unstable. So that it might be asked, what strength of spirit should be used for exhaustion? In one case they had discovered that at a concentrated tincture four times the ordinary strength, it was required to dissolve or extract 10 gals. of catechu with sufficient proof spirit to prove one pint of finished liquid. Could a permanent satisfactory preparation be so made? Again, opium formed a tincture so exact that it might appear to be used for exhaustion, but the being small it was probably better for dispensing purposes than a stronger tincture given in small amounts. If concentrated tinctures were used, then they might be employed for special purposes, rather than for the preparation of the official tinctures.

The President said they were all much indebted to Mr. Jones for his paper.

Mr. John Barlow, in moving a vote of thanks, said that he fully agreed with Mr. Jones that in many cases the method of percolation adopted in the B.P. standard was by far the most useful method of preparing tinctures. He had not found any great difficulty in recovering spirit from moras such as ginger, by washing through with water, but of course it took time. He regarded the tincture of opium he had found it necessary to practically to be prepared in a moist condition and thoroughly softened with the quantity of rectified spirit necessary to recover proof spirit being subsequently added to the mass. Referring to the use of standardised extracts

THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS. (November 17, 189}
in the B.P.C. formulary, and to which Mr. Jones had alluded, was an "up-to-date" process, and could well be extended to many other tinctures. At the same time for many drugs, and particularly where their substances were the fullest the odorous principles, and where consequently the materials should be subjected to as little heat and exposure as possible—especially for small quantities—maceration with the whole of the menstruum, with subsequent pressure and without any additional spirit to "make up," would be thought, have the preference. In recovering the spirit from the marc, Mr. Perry was not clear whether Mr. Jones pressed the marc before transferring it to the still; did he mix the marc with a quantity of water before distilling, or distil without admixture with water? In reference to the standardisation of tinctures, he asked Mr. Jones if in connection with the "shaking out" process for the determination of alkaloids he had tried the device recently recommended, of filtration under pressure, for overcoming the trouble and tedious occasioned by the formation of "emulsions." He cordially supported the vote of thanks. Mr. Jones, in his reply, said that, with regard to the recovery of spirit from the marcs, he passed spirit through sufficient to make the required quantity. He did not press the marc, but transferred it to the still, added a quantity of water, and recovered by distillation. He had not tried the apparatus spoken of by Mr. Perry in connection with the "shaking out" process.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

A meeting of the members of the Manchester Pharmaceutical Association was held on Wednesday last at the Grosvenor Hotel, Manchester. Mr. G. S. Woolley, President, occupied the chair, and there was a large attendance. Mr. J. Rymer Young gave an address on the work of the Pharmaceutical Council during the past eighteen months. This is printed at page 393.

The Chairman in proposing a vote of thanks to Mr. Young for his valuable paper, said the meeting might not agree with all he had said, but they all thanked him for coming from Warrington to give them so valuable an address.

Mr. H. Kemp, Secretary, seconded the motion, which was carried with acclamation.

The Chairman then said that one point in Mr. Young's paper struck him as going to the root of matters. It was about the opposition to the Bill that the Pharmaceutical Society drafted last April. The great object of the Bill was to unite the trade more than it was united at present, and to do away with those bickerings and objections that had done so much harm in the past. As Mr. Young said it was no use crying over spilt milk; and, going back half a century. With reference to the widows clause, the late Mr. Brown and he (the chairman) pointed out when they went to the Council meeting in London in 1870 the harm that the clause was likely to bring upon them. Of course the thing was done, and they had never been able to repair it. Then, as to the sale of poisons, from the very first they ought to have been tackled in a much more drastic manner than it was. From the very first, people who sold photographic chemicals were allowed to sell two or three ounces or even half a pound of cyanide of potassium in a perfectly irresponsible manner, and when it was thought they had not far to go in the matter, it would be in danger of becoming a lost art. It behoved pharmacists to set their face against it. With regard to the preparation of tinctures, no doubt a process, of which they had several examples...
of Sunderland, a very good friend of his, was one of those things he could not understand, as the Bill was calculated to do much good if passed. Mr. H. Kemp said that, perhaps more than some of those present, he had been aware during the past eighteen months of much that had been going on in the Council, not only in that portion of its work which was public through the Press, but also with much that had taken place in private in the committee room. He believed a body of men never existed who had more deeply at heart the welfare and good of the trade than the present Pharmaceutical Council. The members were one and all imbued, he believed, with the feeling that all they possibly could within the limits of their laws. As Mr. Young showed, the widows’ clause had restricted the Council very much, and the apathy that had been laid to its charge had arisen, in his opinion, rather from without; but within the last three or four years there had been a very evident waking up, not only so far as the Council was concerned, but the trade at large was concerned. In going round and speaking to his brother chemists, he found that there was a stronger desire than ever for amalgamation and for rendering support to the Society. That very day he had a conversation with two chemists who were members of the Pharmaceutical Society, and the statement that the Society were no longer was explained. They explained that they had withdrawn because they felt that the Society was not doing much for the trade. The answer was, of course, that the Society could be doing no more for the trade to-day than it was doing when those gentlemen left. If the trade had not supported it, if everybody had followed the example of the two gentlemen to whom he had referred, they would have been in a very much worse state than they were. Anyone who knew anything about the work of the Pharmaceutical Society during the last eighteen months would bear out the statement that the Council had worked “tooth and nail” to enforce the Pharmacy Act against illegitimate trade wherever it had been feasible in any degree, and where the interests of the trade had been assailed by endeavours to patent concoctions containing scheduled poisons, with a view to thwarting the provisions of the Act. He had done a great service to the trade—a very great service indeed. He had more than once permitted to be patented there was no telling where it would have ended. They would have been surrounded very soon by a host of patent medicines, so-called, sold by everyone and anyone without restriction or qualification. Mr. Young also spoke of the changes on the Examining Board, and again rightly that additions and eliminations might well be made in the case of the Council itself. That was a matter on which he (Mr. Kemp) felt somewhat strongly. A little more interest might be taken generally in the election of the Council. If the men who subscribed their guineas would but take the trouble to inquire into the capabilities and utilities of the men who constituted that Council, they would see that it was to their interest sometimes to make a little change at all events. The difficulty was they could not name a man for removal. It would be libellous, or at any rate it would be bad form, to say of this or that man that he was not fit for a seat on the Council. Respecting the Benevolent Fund he would at once say he did not agree with Mr. Young. Individually he could trust Mr. Young and his colleagues to do their very best in the interests of the annuities. He, being a subscriber, he knew there were many who preferred to have a voice in the election of the candidates. Whilst there was that feeling no interference should take place. Anything that would interfere with the income would be a very serious mischance. The income at present was too small, and if there were nothing at all to interest the subscribers, he was sure some of them would fail out. One other thing in connection with the Benevolent Fund he would like to mention. It was a most pain- ful thing to anyone who had the slightest sympathy with human suffering to see a number of individuals who could not be elected this year under any circumstances, and who must be in a most awful condition. The Council, it seemed to him, had increased the annuity from £40 to £50. It would be very much better to elect five candidates at £40 a year than four at £50. Those who suggested the alteration said that £50 was little enough for those who had at one time been in affluent circumstances, and with the money they did not know what they increased the annuity from £40 to £50 and he repeated that it would be better with their limited funds to assist five rather than four. He hoped the Council would see their way if the Fund did not increase to elect more annuitants at a smaller amount. With regard to the Draft Bill his impression was that Mr. Harrison, of Sunderland, did not oppose it in principle; he merely opposed the proposal that the Council should proceed with the Bill in its present unsatisfactory state. While he was quite in accordance with any movement having for its object the consolidation of the trade, at the same time he thought it was useless to proceed with the Draft Bill until he was sure that they were not doing anything to cure the more serious defects of the present Pharmacy Acts. At present there were two classes too many in the Society. If they could all be classed as members it would be a decided advantage. Mr. Young said he would like to see the Society supported by the whole of the people on the Register, but that could never be unless every man who passed his qualifying examination was made a life-member by payment of an examination fee. There were men who would not and there were men who could not join afterwards. There were men who had gone into the medical profession and into the dental profession. In the Manchester district there was one who had become a policeman. The work of amending the Register was not an easy matter. In the Manchester district there were fifty names on the Register, and of the whereabouts of those fifty people he knew nothing. They were not on the Council that should be dead. Nominally there were 15,000 names on the register, but he did not think there were 12,500 actual chemists who were in trade at the present time. Mr. Charles Turner said the Preliminary examination, in his opinion, was a great source of evil. It did not trend to the support of the Members as far as any way whatever. He believed there was a difficulty in raising the standard, and attention was being drawn to the question whether the Preliminary examination was legal. Mr. Brooks wished to know if anything was being done in reference to the time during which candidates were kept in London, and in Edinburgh. Under existing arrangements a candidate might undergo one day’s ordeal and then have to wait a week or a fortnight for a second day. This meant great expense, and he should like to know if anything was being done in that matter. Mr. Hoseason was of opinion that no one could be a competent examiner until he had taught a subject. As Mr. Turner said, the Preliminary examination did not correspond with the Minor examination. To Preliminary, he thought, should include higher mathematics and fall within the scope of the arithmetic. After mentioning in support of the adoption of the metric system, Mr. Hoseason made a reference to the sale of poisons, and said no one but a qualified man should be allowed to sell poisons, then there would be no need for the Schedule. A medical man when he prescribed a certain drug did not label his prescription, and with
should a pharmacist who was qualified to sell poison be compelled to label it?

Mr. Kirkby said Mr. Young had indicated that the Pharmaceutical Society might take proceedings under the 17th section of the Pharmacy Act. That section distinctly stated that the seller of the poison was the person on whose behalf it was sold, and that the poison was to be labelled with the name of the seller. It seemed to him that the Society had not tried how far that section would go in connection with the company trade. Would the Court require the name of the company, or the name of the manufacturer?

Mr. Young, in reply, said that when he spoke of additions to and eliminations from the Council, he was not, of course, alluding to any individuals in particular. He spoke on general principles in favour of a gradual change in the complexion of the Council. Mr. Kemp had spoken of the number of dead men on the Register. He had not thought they were anything like so numerous. With regard to the annullities, when they were raised from £200 to £500 it was not a member of the Council. It was his impression that the change was a mistake, and there were some members of the Council who agreed with that view, and very frequently ventilated it. He should like to say that every member of the Council suffered from the troubles and grievances which afflicted other members of the trade. In addition to the pleasure of participating in the work of the Council, he had also the privilege of listening to grumblings from north, east, south, and west, as to the state of trade. In reply to Mr. Turner, he had to say there was no statutory power to regulate the Preliminary examination, but it was in the power of the Pharmaceutical Council, by agreement with the Privy Council, to regulate it, under the Bye-Laws. He thought something should be done for the convenience of students during the period of examination, but it should be remembered that their numbers were large and it was difficult to make arrangements to suit everyone. He recognised that the meeting did not agree with his views in reference to the election of annuities, but he thought if those present had to listen to the pitiable applications for relief that were made they would change their views.

A social meeting was afterwards held, at which Mr. Alderman Robert Gibson took the chair.

Parliamentary and Law Proceedings.

Proceedings under the Apothecaries' Act.

MEDICAL TREATMENT BY AN UNQUALIFIED PERSON.

At the County Court, Cardiff, on November 7, the Magistrates, Wardens, and Society of Apothecaries of London brought an action against G. Musk. worthy, Cardiff, the sum of £20 for having contravened the Act of George III., the allegation being that defendant had advised and furnished medicine to Mrs. Ryan and John Penlington whilst not duly qualified. Mr. Ryan deposed that his wife being ill he went in search of a nurse, and by mistake called at the house next door to the one he intended to apply at. There he saw the defendant, who told him to rub oil and hot vinegar on the parts affected, and old him a bottle of oil, charging 1s. 1d. He noticed he be name "Dr. Hall" on the house. Subsequently nurse attended his wife, and advised him not to use the oil. For the defence counsel contended that defendant was entitled to sell patent medicines that were not poisonous. Defendant denied that he advised Ryan in any way, and said that he sold the oil at Ryan's request. His Honour gave a verdict for the plaintiffs.—Western Press.

Proceedings under the Medicine Stamp Duty Acts.

SALE OF PROPRIETARY MEDICINES WITHOUT STAMPS.

At Marlborough Street Police Court on November 7, Mr. Hannay imposed fines amounting to £3210s. upon Jefferson Dodd, chemist, 70, Tottenham Court Road, London, for selling proprietary medicines without the proper stamps.—Morning.

Proceedings under the Sale of Food and Drugs Acts.

IMPURE PRECIPITATED SULPHUR.

John Frederick Harston, chemist, High Street, Lincoln, was summoned at the Lincoln City Police Court on November 8, on the information of James Bradley, inspector of weights and measures, for selling, through his assistant, Harry Taylor, precipitated sulphur which was not pure, but a mixture of sulphur and sulphate of lime, namely sulphur 42.5 parts and hydrated sulphate of lime 57.5. Inspector Bradley stated that on the 24th ult. he purchased some of the sulphur for analysis, the result being that the public analyst declared it to be impure. Defendant contended that a different article, milk of sulphur, was supplied by mistake, and was labelled as such. The mistake arose through the assistant being only temporarily employed. The article was not represented on the label as precipitated sulphur. A fine of 10s. was imposed.—Lincolnshire Echo.

Poisoning Cases and Inquests.

POISONING BY POTASSIUM CYANIDE.

Oliver Thackwell, aged 14, died at Bournemouth on Monday, October 29, from the effects of potassium cyanide contained in a solution prepared by his employer, a hairdresser. Verdict: "Suicide, committed while temporarily insane."—Bournemouth Observer.

DEATH FROM OVERDOSE OF LAUDANUM.

Alfred Irlam, aged 33, a lithographer, died at Bradford on Sunday, November 4, after taking laudanum for sleeplessness. Verdict: "Death was due to an overdose of laudanum."—Bradford Argus.

DEATH FROM OVERDOSE OF HYDROCYANIC ACID.

Dr. Kirkman, of Hastings, died on Saturday, November 3. He had been in the habit of taking twelve-minim doses of hydrocyanic acid. An inquest was held on Wednesday, November 7, to investigate the cause of his death. Verdict: "Death from an overdose of hydrocyanic acid, taken accidentally."—Smy.

POISONED BY ACONITE AND BELLADONNA LIQUID.

James Hopping, a hay-trusser, died at Tewkesbury on Thursday, November 8, from the effects of a liniment containing aconite and belladonna, taken by misadventure. Verdict: "Accidental poisoning."—Birmingham Daily Post.

POISONING BY LAUDANUM.

John Graham, aged 39, died at St. Rollox, Glasgow, on Wednesday, November 7, after the administration of a few drops of laudanum from a jug, by his mother.

POISONING BY ARSENIC.

Gad Kilner, of Combsborough, died on Tuesday, October 30, after taking a large quantity of arsenic. Verdict: "Suicide whilst temporarily insane."—Leeds Mercury.
Correspondence.

STANDARDS OF PURITY.

Sir,—We are desired to ask your leave to correct two misunderstandings expressed in your recent leading article on the subject of the draft for a new Sale of Food and Drugs Bill, drawn up by the Council of the Society of Public Analysts. You express objection to the constitution of the proposed Board of Reference for appeal in case of disputed analyses, urging that the Board should include nominees of representative bodies of chemists and of grocers. May we point out that our draft scheme provides for the inclusion—not, certainly, of a representative of the grocers—but clearly of a representative of pharmaceutical chemists and chemists and druggists, viz., "a person nominated by the General Medical Council." It was at first proposed to say "a person nominated by the Pharmaceutical Society of Great Britain and Ireland," but seeing that the official standard for the composition of drugs which we advocate is the British Pharmacopoeia, and seeing that the British Pharmacopoeia is issued under the direction of the General Medical Council, it seemed to our Council, rightly or wrongly, that the General Medical Council should be the body to appoint the representative of the pharmacists. The functions of the proposed Board of Reference would be essentially chemical and analytical functions, in which the representative of pharmacy would necessarily be of direct assistance, while the actual representation on the Board of grocers or similar tradesmen would be out of place. Such a Board, it need scarcely be pointed out, would, however, be able to avail itself to any extent that seemed good to it, of the views of any trades representatives who might from time to time be deputed by existing trade organisations to lay before the Board facts or suggestions arising out of their own practical experience in trade. Another point to which you take some exception is the clause to the effect that "no certificate other than that of the public analyst shall be received as evidence unless supported by the oral evidence of the analyst giving the certificate," and you say that "it is difficult to see why the certificate of that individual should be of equal value as evidence with the oral evidence of other chemist's frequently experts with both greater general and special knowledge than himself." Your exception here appears to be based on misunderstanding both of the law as it exists, and as we propose that it should exist. At the present time the certificate of the public analyst is in itself evidence, but the Sale of Food and Drugs Act allows the accused person, at his option, to require the attendance of the public analyst to support his certificate, and to be cross-examined thereon. It is only when the defendant abstains from taking this step that the certificate of the public analyst is sufficient evidence in itself. On this head our draft bill proposes to make no change whatever in the existing law, but only to point out more clearly to magistrates that a certificate from any other witness than the public analyst is not, and cannot, under any circumstances, be legally accepted as valid evidence without the personal attendance of such witness. The sole object of the provision in so far as the evidential value of the public analyst's certificate is to avoid the unnecessary expense and trouble of the analyst's attendance at the large proportion of undefended cases which occur. When a dispute as to analysis arises, it is only in accordance with common sense, as well as with the law, that the analyst who differ should be summoned to explain themselves, whether they hold an official or an unofficial position. It ought not to be necessary for us to say that the Society of Public Analysts entertains but the most cordial feeling towards the Pharmaceutical Society and the great interests it represents.

WATTS’ DICTIONARY OF CHEMISTRY.

Sir,—Referring to your review of the fourth volume of Watts’ Dictionary of Chemistry, just issued, I desire to draw attention to a discrepancy or ambiguity which occurs in it, and has appeared in each of the three previous volumes, as well as on the book-markers of abstractions which are supplied with them. The contractions "S." and "S. (alcohol)" are defined as meaning respectively the solubility in water and the solubility in alcohol, and are further stated "of a liquid or solid: = number of grs. dissolved by 100 grm. of water. In both cases the temperature is stated." The words "and of alcohol respectively," or others to that effect, are omitted after "water."

Wm. Martinelli.

LEONURUS CARDIACA.

Sir,—I remember some years ago finding Leonurus Cardiaca in the vicinity of Bodiam Castle, Kent. I believe it is also to be found near a few other old places in the country, having no doubt been cultivated in bygone days for its medicinal worth.

Sheffield.
John Austin.

THE DIARY OF THE WEEK.

SATURDAY, NOVEMBER 17.
Pharmaceutical Football Club v. London Welsh R.s. Child's Hill, Crickwwood, at 3 p.m.

MONDAY, NOVEMBER 19.
Imperial Institute.
House Dinner, at 6.45 p.m.
"Malta and its Antiquities (illustrated)," by the Rev. W. K. B. Bedford, at 8.30 p.m.

WEDNESDAY, NOVEMBER 21.
Imperial Institute, at 8.30 p.m.
Ladies’ Concert.

Royal Microscopical Society, at 8 p.m.

Western Chemists’ Association (of London), at 7 p.m.
Annual Dinner at the Café Royal, Regent Street Society of Arts.

THURSDAY, NOVEMBER 22.
Imperial Institute, at 4.30 p.m.
"Australian Hardwoods and their Uses," by Ciss B. Fenwick.
Chemists’ Assistants’ Association, at 8.30 p.m.
"Surgical Dressings," by E. White.

Liverpool Chemists’ Association.
"Some Objects of Pharmaceutical Interest in the Liverpool Museum (illustrated)," by T. H. Whippleworth.

SATURDAY, NOVEMBER 24.
Ponder’s End.

THE NERVOUS SYSTEM IN THE
VEGETABLE WORLD.*

BY J. REYNOLDS GREEN, M.A., 82.D.,
Professor of Botany to the Pharmaceutical Society of Great
Britain, and Dean of the School of Pharmacy.

There are far more fascinating things in the study
which we generally call natural history than the com-
parison which we find it possible to make between
the animal and vegetable organisms. For many years
past the idea that all living nature is composed as
it were upon one fundamental groundwork of living
substance has been gaining ground, and more and
more similarity has been found between the two
classes of organisms which we have somewhat arbi-
trarily divided it into—the animal and vegetable
kingdoms. The attempt that was made in former
times to set up an arbitrary distinction between the
animal and vegetable worlds has broken down at
almost every point, but one thing especially was
laid stress upon as a sort of forlorn hope or point of
reference to which the framework of definitions could
go. We used to be assured that even if plants
could move, which was perhaps disputable, at any
time they could not feel, and the power of feeling, at
any rate, was a final and crucial line of separation.

What is a Nervous System?

Now it is desirable in the first place to under-
stand what we mean by the term "a nervous system." Of course, in the higher animals the thing
is perfectly plain and obvious, but it is not so
obvious, perhaps, when we go down to very simple
organisms. A nervous system, although orna-
mented with a somewhat formidable name, does
not necessarily mean anything extensive. It in-
cludes perhaps three ideas. First, the power of
originating a movement, or some other vital pro-
cess or occult molecular change going on in the
organism itself, as we, for instance, have the power
of initiating movements of various kinds and asso-
ciate them with particular nerves. It embraces,
again, the power of receiving impressions from
without. The powers which we call senses evi-
dently belong to a somewhat different category
than the power of initiating movements. Then we
have finally in the animal world a third factor, a
sort of power of co-ordination by which the im-
pulses, the sensations which we appreciate as
coming to us from without, find expression in
various movements or other things within. Thus
there is in the organism a central power which can co-
ordinate these different classes of things. When
we descend in the scale of Nature to the very
lowest organisms we find those represented in a
somewhat rudimentary or primitive form. The
Amoeba is a little organism which consists primarily
of a lump of some jelly-like substance. It is one of
the humblest forms of life we know, and there
is a very little structure about it. It is chiefly
characterised by the power of changing its form,
ot at all rapidly, but still constantly. If it be
irritated in any way it can roll itself up like a lump
of jelly, and you can see very little more than
fractureless material which is living. It has the
ower of changing its form in consequence of receiv-
ing disturbances which we call stimuli from
without.

In the Myxomycetes or Mycetozoa there is pretty

Vol. LIV. (Third Series, Vol. XXV.), No. 1274.
take advantage of the resting position which it is bound to assume, and this sub-division takes the form generally in the plant of so-called leaves. These leaves have, of course, very definite duties to perform, otherwise no doubt the shape would not be as it is. There is a flattened surface to secure as great an exposure to light and air as possible. The cells, especially on the upper sides, are crowded with relatively large green granular bodies known as chlorophyll grains, which are impregnated in the living substance which lies round the walls of the cell. Each cell has its own complement, and they are very numerous. It is by virtue of these small bodies that the plant is able to take advantage of this factor of its environment. They are the factors which the plant uses to avail itself of the food which is present in the air. We have constantly the power of absorbing a large amount of food by virtue of the exposure of these chlorophyll bodies to the environment. That is the advantage this particular form offers to the plant through the leaf.

The root, on the other hand, impacted as it is in the soil, is especially set apart for the purpose of taking in substances in solution in the water which permeates the soil. The particles of soil are impacted closely on certain absorbing projections on the surface of the root known as root hairs, and a very close connection is between them. So that to take advantage of the environment the plant has laid itself out and sub-divided its upper surface to such an extent as to expose these chlorophyll bodies to the light, and it has developed at the same time, in the lower portions in particular, the sensitive regions known as rootlets, which are absorbing regions. It is a question of adaptation, no movement being possible, and a large increase of surfaces has been reached, so that the loss of movement may not be felt.

Now certain dangers attend an environment of this kind. The light may be too strong, or it may be too weak. There is a maximum, or an optimum, at which vital processes go on best. On the other hand the root, in penetrated soil, may very likely be injured by coming in contact with or growing down on to certain portions of stone, or other impervious substances, from which they could get no nourishment, and would probably lead to the destruction of their tissues. Again, the temperature may vary considerably, and such variation may bring certain dangers with it. We have, then, in studying the life processes, and particularly the nervous processes, of plants, to bear in mind what the plant wants, how it can get it most readily, and from what dangers it can be defended.

Tendency to Sensitiveness in Plants.

We may pause here for a moment to ask ourselves whether plants show any general tendency to sensitiveness, whether they are rigid bodies with no power of reaction in general, or whether we can see a foreshadowing of something like what we ourselves feel in a general susceptibility to changes in external conditions. We find an instance of this in the plant known as the telegraph plant, Desmodium virginianum, which has two little wings upon the curious leaves. When the plant is in favourable conditions these little wings are continually moving up and down; perfectly spontaneous movements, which go on re-
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS

November 21, 1894.

A response rather than in the appreciating of the disturbing cause.

The so-called affrent or sensitive mechanisms are those by which an organism appreciates any change taking place in the outside; we speak of sight and taste and smell, and so on. We appreciate these things by particular sense organs, but you know, of course, they are used by particular variations of the environment through special mechanisms. That is the first thing then, the reception of an impression, and then the last thing is a particular movement which generally results, in which some other part the organism is concerned than the other part which receives the impression. Between these we must have a third. We have a co-ordinating mechanism by which the impression received finds its exposition in the movement, or whatever form it may take, which follows the reception. There are, then, these three things to bear in mind, and we have precisely the same thing in the plant as we have in the animal, but the differentiation has gone in a very different way. In the animal the great perfection of the whole thing is seen in the response. In the plant, the great delicacy is seen in the sensibility, and in some respects plants are more sensitive to impressions from without than animals. The response to the stimulus is very difficult for the higher plants to manifest, and that, perhaps, may be the reason why the sensitiveness is that which we study mainly. The plant is fairly rigid, an animal is perfectly free, not only itself, but all its parts in a way are rigid, the only part of the stem which is capable of very much movement is the young growing portion, which, of course, is plastic, and it is consequently most always in connection with the process of growth that we find the responses to irritability most easily manifested, though it is not so entirely.

The Power of Vision in Plants.

First of all, as to these sensations, the plant has rudimentary power of vision. Of course it is not what we should expect of a plant and in the condition of things. But what do you mean by vision? In its very rudimentary form it simply means an appreciation of the difference in the amount of light. The man who is nearly blind may be able to see a faint glimmer of light, and so long as he has that power his sight is to a certain extent present. Of course every higher differentiation gives him more and more power of vision, until we get to the complete vision which we ourselves possess; but still you see there are a series of gradations from complete to incomplete, and I think to get to the very bottom we must consider that the power of appreciating differences of light is at any rate a rudimentary vision. In various lowly plants certain of the cells produce very curious little bodies furnished with uncommonly fine, delicate tails. These are the swarm spores, so-called because they come out in swarms from particular cells. When they get into the water in which the plant lives they are found to be always moving about, and so long as the conditions are favourable—so long as their life lasts, that is—they continue to move. If you have a slide of this stage under a microscope, and you watch them moving about, you find them doing it in a sort of irregular manner; but if you pass a strong beam of light—sunlight preferably—through the slide, they at once alter their movements and take up a very definite position with regard to the beam you are sending in. There are a great many of these organisms which show this power, giving in answer to the stimulus their particular responses. They are endowed with different degrees of sensitiveness. Some prefer a strong light, and go to it, some avoid it as far as possible, and like to get into the shade. This illustrates the point that there is a rudimentary power of appreciation, differences of light, and that this power varies in the different organisms. An adult plant has, to a certain extent, the same power. It cannot manifest itself in the form of movement as it can in these swarm spores, but it does so if a change in the direction in which the plant assumes while it is growing. The peculiar sensitiveness which we speak of is known in botanic treatises under the name of heliotropism—the power of bending in response to the rays of the sun. When a plant in a growing condition is exposed to a lateral light it seems to be able to appreciate that light, and to turn itself towards it. As an illustration of this, some plants of canary grass were grown in the dark, one saucercul perfectly in the dark, and the whole tendency of the plants in it was to be vertical, to grow upwards. Another plant was grown under a box which had a little hole in one side through which light was able to penetrate to the young plants. The tendency of the plants was to make them bend straight from the window. No doubt those who have indulged in window gardening, as it is called, have seen the tendency plants have to curl over towards the illuminated side and expose their leaves to the light. This is the same thing. Evidently the plants which have grown there have had the power of seeing that window, and they have gone for it. By a consideration of similar experiments to that, we may ascertain a few more facts about this power of vision. In Mr. Darwin's book on the movements of plants he describes some experimental work made with grass. One of his experiments, illustrates the extreme sensitiveness—the extreme power of vision, if you like—that these small things have:—

A pot of seedlings was raised in the dark. They were placed, when they had once begun to grow, in a dark room opposite to a very small lamp at a distance of 12 feet. The light, Mr. Darwin says, was so feeble that when he was in the room he could not see the pot of seedlings by it, and when he had a piece of paper with a pencil mark on it there was not light enough to see the pencil mark, so that you could not accuse the thing of wanting very intense illumination. In 7½ hours from the time when they were exposed to this very small light they had made a distinct curvature in the direction of the lamp. He said they went diametrically for it, so that lines drawn through one of the plants would point to the very centre of the illumination. This is only a very rudimentary form of sight, but still the sensitiveness is certainly comparable with that of the human eye. There is of course no power of complexity of vision, but as far as mere sensitiveness goes it is fairly comparable.
The next point which came out of these experiments is that the sensitiveness is not a general tendency, that it is not a phototonic condition finding its expression in that way, but that a very definite portion of the plant must be stimulated, and another very definite part performs the movement. This leads up to what is the essential feature of the nervous system, the power of interpreting a stimulus and expressing it in the form of changes in some other part of the plant altogether.

For instance, an experiment was made in this way:—Some leaves of the English ivy were covered with little tin caps, the caps were arranged so as not to press upon them or weigh them down, but just to cover the tip, and we found that when the tip was covered one-fifth of an inch from the apex, which is no very great distance compared with several inches of growth, then the plant behaved as if there were no light at all. The one-fifth of an inch was the only sensitive part; if that were left exposed and all the rest of the plant covered the movement went on as at first. In that little portion lies the power of receiving stimulus; therefore one could not go wrong in saying that the little tip had served as the sense organ as definitely as the eye of an animal.

With regard to the power of response which the plant has, not to seeble, but to very brilliant illumination, cells taken from the surface of a leaf of Oxalis, in their normal condition, have their chlorophyll grains lying in such a position as to expose their broad surfaces and almost the whole number to the incident light, so that the chlorophyll shall get as much light as possible, but under conditions of brilliant illumination we find that they change their position; the sun has caused them, as it were, to get out of its way. They slowly move under a bright illumination, and from some idea of preservation, no doubt, we find them gathered together on the ends of the cells where they get as little light as possible, and instead of presenting their broad surfaces they are turned on their edges. This is an effect which the plant brings about when stimulated by too high a light. A sensitiveness which is, perhaps, not so startling to consider as the former one, but which still has a very definite part to play, and may almost be compared to the effect produced on our own eyes when we expose them to the glare of the sun.

Certain other plants protect themselves in a similar way from too intense illumination, not by change in cells in any way, but by turning the edges of their leaves to the incident rays, instead of, as is normally the case, their flattened surfaces.

The Sense of Touch in Plants.

Perhaps the most prominent sense you would expect a plant to possess is that of touch. One can well believe them capable of responding to this. We may subdivide sensitiveness to contact into three heads. We may have an appreciation of temperature—that is a sensitiveness which we of course feel ourselves; we may have appreciation of contact itself without temperature—touch proper; and we may have, again, the appreciation of dampness or moisture. We have all these illustrated in the plant. Firstly, we have a reaction. Now when temperature falls suddenly, and the plant is in the phototonic condition, a great many plants respond to it in a very peculiar way. They are inac-
the work was also done in the Pharmaceutical Laboratories of the Owens College by Hoeasen and myself. Our thanks are therefore due to Prof. D. J. Leech for his kindness in allowing us to carry on our investigations there.

The petroleum ether, absolute ether, absolute alcohol, and chloroform, employed in extracting, were either redistilled or examined by ourselves. Working on several samples of the drug obtained from various sources, we found all to be difficult to powder. No. 60 powder was employed.

1. Maceration and percolation with pure petroleum ether yields 3-634 per cent. of a greenish-brown extract, hardly volatile when exposed for half an hour on a water-bath. It consists of a fat, whose base is not glycerol, but probably one of the waxy alcohols, and whose acids are palmitic and lauric, with perhaps others. It melts at 38°-5 C. A wax resembling Japan wax (Rhus succedanea) is present, and a pigment made up of at least one well-known body—xanthophyll. The pigment is most difficult to get rid of, being found in all the extracts. It was obtained in crystalline form. Glucosides and alkaloids are absent.

II. Maceration and percolation with absolute ether gives 1-940 per cent. This extract is chiefly composed of a series of acid resins and resin anhydride, one or more of which are soluble in 0-75 per cent. sodium chloride solution. These resins probably play the part of glucosides in their pharmacological and therapeutical action. Glucosides and alkaloids are absent. Tannin, and benzoic and salicylic acids were tested for, but could not be detected.

III. Absolute alcohol gives 0-982 per cent. of extract, and is made up of a small amount of resin or resins and colouring matter. Glucosides and alkaloids are found to be absent, but when the extract is boiled or three hours with dilute sulphuric acid, the solution reduces Fehling's solution. This may be due to the presence of some body capable of inversion, or to the presence of a substance of the nature of tannin.

IV. The drug next treated with chloroform gives 1-122 per cent. of yield. This consists of wax, pigment, tannin (or some similar body, although it is difficult to account for its presence after the previous exhaustive treatment). No alkaloid could be detected. After this successive treatment glucosides or alkaloids, if present to any extent, could hardly have been missed.

The dry drug left was found to be highly interesting, and some months were spent in working out the less important constituents, but professional duties prevent me from writing up the interesting steils, and I can do little more than mention a few striking points. As before, glucosides and alkaloids are tried for, but without success; and, for comparison's sake, in each case dilute solutions of glucose and some alkaloids were tested with each reagent.

A watery extract is found to be fluorescent, viscid on when very dilute, and almost devoid of taste; an alkaline solution treated with excess of dilute hydrochloric acid gives no precipitate, showing that a casein (legumin) is most likely absent; and another portion treated with dilute solution of sodium chloride and then with saturated solution (after filtration), gives no precipitate, showing probable absence of a fibrin. The thick extract does not coagulate on boiling. Alkaline pancreatin, when added to it and kept moderately warm for hours, makes it much less viscid, and the application of caustic soda solution and a trace of sulphate of copper solution gives a dirty pink coloration. It may be that pancreatin can split up the vegetable analogues of animal albumin. Boiled for three hours with diluted sulphuric acid, the glucose resulting from inversion stands only at 0-155 per cent.

Pectin was separated out and found in straw-coloured shining scales, and was present to the extent of 7-58 per cent. Vegetable mucilage was got in light brown scales, and amounted to 7-025 per cent. Cellulose was also obtained in scales, but not free from colour, and gave 2-375 per cent. Cutsone could only be got with difficulty, and was calculated by the amount dissolved by boiling caustic potash solution, and was equal to 8-64 per cent. The lignin stood as high as 21 per cent. Starch was sparingly present, but showed a variety of shapes.

The ash reacted to the bases potassium, sodium, calcium, and to sulphuric acid. Nitric, hydrochloric, and phosphoric acids were tested for, but could not be found.

Every point mentioned was gone over more than once, but a complete detailed analysis was not carried out for the reasons already mentioned.

FORMATION AND LOCALISATION OF FATTY AND ESSENTIAL OILS.

M. E. Miesnand has investigated the distribution of fatty and essential oils in a variety of plants. He finds that, except in the case of grasses, they are not localised in special layers of cells, but are found in all the cells of a particular region, such as the endosperm, pulp of fruit, leaf, rhizome, etc. In seeds the albuminous reserve substances have a similar distribution, and there appears to be an intimate relationship between the two classes of substances. They have, however, an entirely independent origin; in fruits, leaves, stems, etc., the fatty oils are not accompanied by albuminoids. The former are produced within the chlorophyllous protoplasm. The disappearance of the reserve oily substances is not the result of the action of any special diastase (saponase). In the seeds of grasses, on the other hand, which may be regarded as oily seeds with an external reserve of starch (endosperm), the starchy substances are assimilated by a diastase (amylase) elaborated in a special epiderm. In the flower the essential oils are usually found localised in the epidermal cells of the upper or under surface of the petal or sepal; in the leaf they are found in the epidermal cells of the upper surface; in the stem and fruit in the epidermis. They appear always to be formed in the chlorophyllous protoplasm, after having passed through the intermediate stage of tannoid substances. In its decomposition, the chlorophyll gives rise also
to other substances, such as tannins, latex, pigments, etc. Hence, white petals, in which the transformation into essential oils has been the most complete, are frequently the most strongly scented; while brown and orange petals, in which pigments have been produced in large quantities, are more often scentless. (Annales des Sciences Naturelles, Botanique, 1894, pp. 257-397).

Contributions to the Chemistry of Cerium.*

By W. M. Dennis and W. H. Magee.

(Concluded from page 578).

IV.—The Hydroxides of Cerium.

The peculiar colour changes of the hydroxides of cerium have often been noticed by chemists who have experimented with that element. When any one of the alkaline hydroxides is added to a solution of a cerous salt a white hydroxide is precipitated. This, so most authorities state, becomes slowly yellow on exposure to the air, more rapidly if chlorine or other oxidising agents are present. Poppius, however, claims that he obtained a dirty violet hydroxide by leading chlorine into a solution of a cerium salt precipitated by an acetate. This he claimed to be a higher hydroxide than the yellow. He states that it gave on ignition a red oxide. Others have claimed that his violet hydroxide was a basic acetate. Rammelet-berg obtained a like-coloured hydroxide by precipitating a hot solution of cerous-cer酸 sulphate with caustic potash. Hermann and Stapf also obtained peculiar hydroxides, to which they attempted, without much success, to assign formulas. Later Lecoq de Boisbaudran, by the addition of ammonium hydroxide and hydrogen peroxide to a solution of a cerous salt, obtained an orange-red precipitate, which was studied by Cleve, who, as a result of his observations, considered it the hydroxide corresponding to an unknown CeO₂; namely, Ce(OH). The following observations may throw some light upon the matter. A solution of mixed chlorides, containing lanthanum, didymium, and cerium was boiled and precipitated, while hot, with ammonium hydroxide. This was done in a large bottle which could be tightly corked. The mixed hydroxides were almost perfectly white, having possibly a faint pinkish tint. After the hydroxides had settled, the supernatant liquid was poured off and the bottle was refilled with thoroughly boiled distilled water. This was repeated until all foreign salts had been removed, the bottle being kept closely stoppered except while decanting and refilling. The hydroxides suffered no change of colour upon standing for some days. Therefore, cerous hydroxide and the hydroxides of didymium and lanthanum when mixed are almost white. Didymium hydroxide by itself, however, or without much intermixture of white hydroxides, has a pinkish colour.

Finally, air was blown through the suspended hydroxides. The colour rapidly changed, at first to a dull purple, and finally to a pale yellow.

Next a solution of cerous chloride was treated in the same manner. The hydroxide remained perfectly white while air was excluded, but, being exposed to air, it took on a dull purple colour, changing later to a bright yellow. Through another similar process, air freed from carbon dioxide was passed; the same change in colour resulted. Through yet another, pure carbon dioxide was passed. It remained white and did not change to purple even when, after some time, air was substituted for the carbon dioxide, the stability doubtless being due to the complete transformation of the hydroxide to the carbonate. Through yet another sample, air from which both oxygen and carbon dioxide were removed, that is, nitrogen, was passed. It remained white. Next a bottle was about one-sixth filled with cerous chloride, and this was precipitated—white—with ammonium hydroxide, and the bottle was then filled with unboiled water and lightly stoppered. The precipitate changed in color quite rapidly to light purple, which gradually became darker from above downward, and finally the tap began to change to yellow. After about four months the upper third had become yellow, that below being still violet.

Both the white and the purple hydroxides when washed on filter paper, dried at a low temperature, then ignited, gave an olive-green oxide, which did not become yellow even when the highest heat of the blast-lamp was applied. On powdering it very finely it seemed more nearly yellow. The weights seemed to agree well, however, with that called for by the oxide. The yellow hydroxide when dried and ignited gave a pale yellow ceric oxide. When the yellowish white oxide prepared by this method or by igniting the oxalate is again ignited over the blast-lamp, in an atmosphere of hydrogen, it becomes olive-green with marked loss of weight. For example, 0.125 gramme of yellow oxide ignited in hydrogen weighs 0.1261 gramme; 0.1574 gramme similarly treated gave 0.1570 gramme. When again ignited in air or oxygen, the oxide became yellow and regained its original weight. Bunseen obtained very similar results.

As mentioned in a previous section, the precipitate obtained by the united action of ammonium hydroxide and hydrogen peroxide, on being dried and ignited, gives a pink oxide, which seems to weigh somewhat more than ceric oxide, CeO₂, should.

Another point, perhaps worthy of notice, was that when some of the purple hydroxide was dissolved in sulphuric acid and allowed to stand for a few days there separated out a crystalline sulphate which, by analysis, gave results too high for ceric and too low for ceric sulphate.

It is to be concluded then, so far as the present observations go, that cerous hydroxide is white; that on exposure to oxidising agents, including atmospheric air, it becomes first purple and then yellow, or, in other words, the purple hydroxide is an intermediate product.

* Ann., 105, 40.
require removal of the restrictions applying in the United Kingdom. It might be provided for by a special supplementary regulation applying only to the particular colony. In the case of essential oils which are now officially directed to be "distilled in Britain," there may be, for other reasons, sufficient ground for removing that restriction, provided the definition of the several oils by characters and tests, were so far improved as to render their identification practicable.

The official limitation of opium to the "produce of Asia Minor" might be objected to as unreasonable in view of the fact that opium containing as large an amount of morphine can be also abundantly produced elsewhere. But that objection would involve the assumption that morphine is the sole active medicinal principle of opium, and a disregard of the firmly established medical opinion that the action of opium is not fully represented by that of an equivalent quantity of morphine.

The fifth recommendation to omit certain drugs and preparations now included in the Pharmacopoeia relates to matters which are outside the province of the pharmacist, and they must be decided from the medical point of view. But whatever may be the opinion held in Australia, it is certain that several of the drugs and preparations now referred to as being unused there and unnecessary are in constant use in Britain, as, for instance, spirit in therapeutia armoraciae co., oleoresina cubebe, emp, calefacientes, cinchonidinum, and ext. tarax. liquid.

The drugs and preparations specified in Appendix D as being suitable for insertion in the new Pharmacopoeia are most of them in every day use, and many of the preparations have been adopted in the unofficial formulary of the British Pharmacaceutical Conference. But before coto bark or β-naphthol are adopted as articles of the official materia medica of an imperial pharmacopoeia it would be desirable to have some better knowledge of their medicinal value than is at present possessed. From the pharmaceutical point of view a glycerinum acidi boric is more suitable for introduction as an official preparation than "boroglyceride," as suggested, and the preparation might, perhaps, be substituted for the present glycerinum boracic.

The pharmacy of eucalyptus preparations might well be amended, but the oil and mucilage suggested in the formula for syrup. eucalypti rostrato appear to be unnecessary additions, and the suppositories made according to the formula given for suppos. eucalypti rostrato would be more properly named suppos. nucis vomicae. It is not evident what advantage would be gained by making the ointment of eucalyptus with the fresh leaves in place of the oil as at present.

If all the colonies suggest as many alterations as Victoria has done, the work of revision will be very materially extended, and its difficulty in-
increased. Having regard only to the additions which have been suggested as desirable, it may be feared their adoption would render the Pharmacopoeia unnecessarily voluminous, while some of them would be better suited for a text book. The more, therefore, the project of making the Pharmacopoeia applicable to all parts of the British Empire is considered, the more it becomes apparent that this adaptation may most conveniently be made in the form of supplementary provisions for the special requirements of the several colonies.

**THE DANGERS OF LEGISLATION.**

The editor of the Canadian Pharmaceutical Journal refers, in the November issue of that publication, to the result of the ARMSON case in England, and writes in terms of approval on the decision that the sole right to vend proprietary medicines containing poison, in Great Britain, remains vested in registered pharmacists. He then proceeds to contrast the different state of affairs prevailing in Ontario, where the outcome of somewhat similar proceedings has been practically to ruin the local Pharmacy Act.

That Act was based on the British Act of 1868, and possesses the same merits and defects as the latter, and it is pointed out that, if the Council of the Ontario College had acted as wisely and energetically as the Council of the British Society, the condition of things might have been equally fortunate. The main result of the Eaton prosecution—which was referred to in the Pharmaceutical Journal for October 22, 1892, and in which it was sought to obtain penalties from a limited liability company for the sale of chlorodyne—was to lead to the legal exemption of proprietary medicines from the operation of the Ontario Act.

A conviction was obtained in the Eaton case, but public opposition had been aroused, and when, subsequently, an attempt was made to pass an amending Bill to the Ontario Act through the Legislature, it was passed with the addition of a clause which entirely prevented the application of the original Act to the trade in patent (proprietary) medicines, and privileges were thus lost which had only been secured by years of persevering effort. The attempt to amend the Act is said to have aroused the opposition of the Colonial Government, the press, and the people, and resulted in a strong feeling against class legislation in general.

British pharmacists may profitably ponder over this unlooked-for effect of seeking to gain extra parliamentary powers, and after reflection they may decide that in such matters it is desirable to hasten slowly, making certain of the soundness of their case before putting it to the test. It is also a good thing to investigate the state of affairs generally, elsewhere than in Great Britain, and to that end we propose next week to contrast the condition of pharmacy at home and abroad, especially in the colonies and other English-speaking communities.

**THE T. C. W. MARTIN TESTIMONIAL.**

Many of our readers are probably aware that an influential Committee has been formed to press Mr. Martin with a testimonial, to indicate in a practical manner how much he is esteemed and respected by those with whom he has come in contact during the many years he has represented the well-known house in which he has recently completed fifty years of honourable service. We understand that the response has been very satisfactory.

The Committee has decided that the testimonial shall take the form of a purse and a illuminated address bearing a list of the subscribers. The presentation by Mr. E. N. Buttt, Chairman of the Committee, will take place on Wednesday, December 5, at 6 p.m., in the Hall of the Pharmaceutical Society, 16, Bloomsbury Square, by permission of the Council. Subscribers and friends, ladies as well as gentlemen, are invited to be present.

The fund will close on November 30, by which time it is hoped that those subscribers who have remitted the amount of their subscription will forward it to Mr. M. Cartege, Treasurer, 27, New Bond Street, W.; or Mr. W. F. Banker, 14, Braxfield Road, Bromley, S.E.

**COLONIAL AND FOREIGN ISSUE.**

The Journal of Saturday next, December 1, will have a wide circulation throughout the Colonies and it has, therefore, been thought a fitting opportunity to publish articles comparing the condition of pharmacy at home and abroad, and others on the approaching revision of the British Pharmacopoeia. Information published in this number of the Journal will reach some five thousand individuals connected with the pharmaceutical industry of the world, who do not usually receive it. We would remind our readers that notices, etc., publication next week should arrive not later than the first post on Wednesday morning, November 28, and advertisements should reach the office, 6, Serle Street, Lincoln’s Inn, W.C., as early as possible during the same day.

**TEMPORA MUTANTUR.**

A report of the proceedings at the first meet of the new session of the Royal Society appears in the Times of last Saturday, with brief abstracts of the papers read at the meeting. This is a first indication of a new departure, which shows that the necessity for adaptation to progress has been observed even by so powerful an institution as the Times.

**HOSPITAL PHARMACOPEIAS.**

The necessity for the existence of hospital pharmacopoeias, as urged by a correspondent in the present issue of the Journal, is of course a real one, so long as limited dispensing staffs are employed in hospital dispensaries. At the same time, however, such pharmacopoeias ought to be limited in size, embracing only the commonest remedies, and not attempt to compete with the general standard—the British Pharmacopoeia. As indicated by the revcr
of one such work on page 430 grave mischief may take its rise from this tendency to unduly comprehend much that is elsewhere provided for; and in such cases, if, as Mr. Harvey suggests, the use of hospital pharmacopoeias "is more often honoured in the breach than in the observance," the general advantage will certainly more than compensate for the seeming neglect.

BEESWAX AND PARAFFIN.

We understand that in consequence of the frequent occurrence of wax containing a more or less considerable proportion of paraffin, the attention of the authorities charged with the administration of the Food and Drugs Act has been directed to this matter, and that samples of white wax have been obtained for analysis. It may be suggested that the modern practice of keeping bees in the production of honey, by supplying their hives with artificially prepared foundations made of solid paraffin on which to build the honeycomb, would appear to have become very general, and to have been attended with the unexpected result of introducing into much of the beeswax met with in trade an admixture which may be regarded as an adulteration. If that be the case, the fact might possibly account to some extent for the presence of paraffin even in white wax, but in any case chemists will require to satisfy themselves of the purity of this article, which would be regarded as a drug when supplied by them.

WESTERN CHEMISTS' ASSOCIATION OF LONDON.

The opening of the new session was inaugurated by the members of this Association and their friends, on Wednesday evening, when the annual dinner was held at the Café Royal, Regent Street. The chair was occupied by Mr. Andrews, the retiring president, and between sixty and seventy were present, including Messrs. C. B. Allen and W. Martindale, members of the Pharmaceutical Council, Dr. Luff, Dr. Paul, Mr. Richard Bremridge, and others, the number being larger than on any former occasion. At the conclusion of the dinner, and after the usual loyal toast, the chairman proposed the "Success of the Western Chemists' Association of London," and coupled with the toast the name of Mr. R. H. Parker, the new president. In a brief but well-turned speech, Mr. Parker referred to the rapid growth of the Association, which, after only six years of existence, included more than one hundred and thirty members. Afterwards, in proposing the toast of the "Pharmacetical Society," Mr. Parker spoke of the necessity of supporting the Pharmacetical Society, which, he said, should include every registered chemist. In this way only could the Society influence legislation satisfactorily, and effect the utmost good for its members. Mr. C. B. Allen, in responding, described the difficulties under which the Council of the Society laboured, and referred to the extreme loyalty to the Society manifested by the Association.

Other toasts followed, being interspersed with recitations and songs. Allogather, a very pleasant evening, was spent, and the Association—which might well consider the desirability of changing its style to the London Chemists' (or Pharmacetical) Association, because of its representative metropolitan character—is to be congratulated on the favourable prospects under which it has commenced another year's work.

MISCELLANEOUS NOTES.

The opening of the Pharmaceutical Society's new Hall and Laboratories in Edinburgh, will, as previously announced, be celebrated by a dinner of Scottish pharmacists, to be held on Thursday next at the Royal Hotel, Edinburgh, at 6.30 p.m., and a conversation at the Society's House, 96, York Place, on the following day, at 3 p.m.

In the list just issued of the successful candidates at the recent examination for the B.Sc. degree of the London University appears the name of Mr. H. Holbache. Mr. Holbache, who served an apprenticeship in pharmacy with Mr. Park, pharmaceutical chemist, of the Hagley Road, Birmingham, was an old student of the Midland Institute in that city, taking there a scholarship to the Royal College of Science, South Kensington. He is now one of the lecturers in chemistry and physics in the School of Science, Leeds.

The Annual Smoking Concert of the Pharmaceutical Football and Cricket Club will be held on Tuesday, December 11, at the Lindbergh Restaurant. Professor Green, S.D., Dean of the School of Pharmacy, will take the chair at eight o'clock and be supported by other members of the teaching staff. All former students of the School of Pharmacy are invited to be present. Tickets, one shilling and sixpence each, may be obtained from the Secretary, Mr. T. Tickle, 17, Bloomsbury Square, W.C.

The Christmas course of lectures adapted to children, at the Royal Institution, will be delivered by Professor J. A. Fleming, F.R.S., Professor of Electric Engineering in University College, London. The subject will be, "The Work of an Electric Current," and the first lecture will be delivered on Thursday, December 27, at three o'clock.

According to Professor Crookshank no less than 751 students, mostly qualified medical practitioners, have been instructed in bacteriology at King's College since the foundation of the bacteriological laboratory in 1886, the entry for last year amounting to 171.

A special meeting of the Glasgow and West of Scotland Association is to be held on Wednesday, November 28, when the President of the Pharmaceutical Society, Mr. M. Cartwright, will be present by invitation and address the members.

The inauguration of the 141st session of the Society of Arts took place on Wednesday evening at the Society's Rooms, John Street, Adelphi, when the Chairman of the Council, Major-General Sir John Donnelly, K.C.B., delivered the opening address. In this he suggested that, following up its past work in promoting technical instruction, the Society of Arts should take the initiative in establishing unity of action among the various bodies now endeavouring, in a partial manner and at some disadvantage, to carry forward that important work.

The new volume of the British Pharmaceutical Conference proceedings, including the usual abstracts of papers in pharmacy, materia medica, and chemistry has just been published.
Transactions of the Pharmaceutical Society of Great Britain.

EVENING MEETING IN LONDON.

The first ordinary meeting of the Session was held on Wednesday, the 14th inst., when the chair was taken at 8 p.m. by the President, Mr. Michael Cartelge, who at once called upon Professor Green to give his lecture on "The Nervous System in Plants," a full report of which will be found at page 418.

At the conclusion of the lecture, the President said the meeting was not competent to discuss it, but he was sure that if anyone present wished to put a question Professor Green would be kind enough to answer it.

A member asked if it were not the fact that after a Drosera had made what use it could of an insect, it threw out the débris from the plant?

Professor Green said the tentacles expanded again, and the prey was abandoned, but there was no active rejection of it.

The President then proposed a hearty vote of thanks to Professor Green for his admirable lecture. The matter, as was always the case, was good, but he thought no previous discourse had been given with such exquisite simplicity. The elder members, as well as the students, felt it a great pleasure and privilege to have the opportunity of listening to such a lecture.

The motion having been carried by acclamation, Professor Green thanked the meeting for the patience with which they had listened to his brief exposition of a subject which was of great interest to himself, but which he had feared would not be so interesting to others.

The proceedings then concluded.

Proceedings of Societies in London.

SCHOOL OF PHARMACY STUDENTS’ ASSOCIATION.

The first meeting of the session was held on Thursday, November 15, Professor Atfield, F.R.S., President, in the chair. After the reading of the minutes, and some opening remarks by the President, Mr. Hampson delivered the following address:

INTRODUCTORY ADDRESS.

BY ROBERT HAMPSON.

Treasurer of the Pharmaceutical Society.

In accepting your President’s invitation to address you, at this, the opening meeting of the 30th session of your Association, I felt that I might be able to say something, if but little, not quite unprofitable or unworthy of your hearing. An Old Boy’s ideas and thoughts, given after life’s meridian is passed, may carry a certain weight and guidance, if only to give a friendly encouragement and a friend’s greeting. You, my young friends, who are pressing onwards towards the arena of active life, remind me of a fleet of trim-built ships leaving a landlocked harbour for the great ocean beyond, every one with his own rudder and compass to guide and give him a safe and prosperous voyage. An old proverb says that “In a calm sea every man is a pilot.”

It is, however, well to remember that both captains and pilots are of use only when trained and experienced, and that training and skill come by buffets and storms.

For a few transitory minutes then, this evening, allow me the privilege of occupying the position of a temporary pilot, as well as a friend. I certainly have been buffeted; I have felt also the impact of sundry storms.

It is not fitting, and it is certainly not necessary, that I should offer you particular advice with regard to the special studies appertaining to the calling you have chosen; safer counsel you can readily obtain from the distinguished professors of the School of Pharmacy. I desire rather to inspire you with a genuine student’s glow and devotion; to help you to realise its full value the time most opportune, with which you will deal whilst spending the few fleeting months at 17, Bloomsbury Square, and as members of the School of Pharmacy Students’ Association.

I suppose most of you have left your homes some distance away from this big labyrinth of London. To each of you personally the time spent, and to be spent, here in the development of your minds, is of greater import than the discovery of America by Columbus, or any other great but impersonal event recorded in the history of the world. An American poet expresses my meaning thus:

“Small is the theme of the following chant, yet the greatest—namely, one’s self—that wondrous thing, a simple, separate person.”

You are bent upon study, upon work, for you are all members of your own Association; this I regard as a sign and guarantee for you all of mental thrift and earnestness of purpose.

The special object before you is doubtless the polishing of your mental weapons, wherewith you may, with due dignity, cut your way through the examination room, in spite of the considerate but grim examiners waiting there for you. You desire, however, not only to creditably pass your examinations, but also to make a goodly crop of brain-impressions in the sodding of your knowledge seed, which may serve as a basis for future mental work. Every real student is a real student always.

“Unto him who works and feels he works,
This same grand year, the golden year, is ever at his doors.”

The structural basis of the mind and character is a grave and established fact in human knowledge. “The most universal quantity is diversity.” So said M. Saige a many years ago, and he was right. Amongst you all there are not two of you alike in face, in voice, or figure. There are not two of you of the same mental and bodily potentiality; you are all and each of you “separate persons,” of distinct individuality, and of different mental natures and calibres.

If you started in life—in student life—equally poised, and with equal mental calibre, you might run an equal course—provided your environment remained the same. What an uninteresting and strange set of beings you would be under such impossible conditions and circumstances! Something like an ordinary row of poplar trees in a Dutch garden, of exactly the same...
height and character and growth. One would want to cut them down to get them out of sight!

It is the motif element in mankind and in nature from which beauty and interest and development and originality proceed. If we were all alike, all cut out of the same block, the effect on the mind would be like listening to one dull musical phrase, and only one; and the result utter stagnation and a dead world!

So to every person his own special personality is of paramount interest and necessity.

He must grow his own seed, he must enrich his own mental soil, prune his own mental growths, cut down relentlessly any wild weeds which, having grown, would endanger and besmirch his mental health and purity. To use a homely saying, "he must paddle his own canoe!" "He must hit the ball from his own bat!"

Whilst impressing upon your attention this view of mental growth and development, which to some minds presents an aspect of life almost too sombre for satisfaction, I must remind you that it harmonises with nearly all, if not all, philosophies and systems of ethics the world has yet produced. You remember well the parable of the sower?

Make then the best of yourselves—no second best will do—and leave nothing to so-called chance and to opportunities which may never come. The present is your great opportunity, and for the time being the greatest—to be seized with both hands. You need not fear stocking your minds too well whilst your powers of digestion are good and vigorous. Nothing you will tend to be valueless, the smallest and least interesting joy in science or life is worth knowing.

In my early student days there were some things I found difficulty in understanding and remembering, and files of despair at times crept in upon me. But ow surprising the experience of the coming day! After aching had another set-to in the freshness of the morning my fears evaporated in sunshine, and hope swelled.

So it will be with you, when difficulties like dead alleys rise before you, and only your own concentrated ill-power directed against the obstacle will enable you to pierce the barrier. But what are the after facts of honest effort so expended, when your best efforts have been engaged in conflict!

A sense of no ordinary joy and of triumph will fill our hearts, and best of all, besides the good storage 'knowledge gained, is the increase of mental strength id pliability ready to serve you well at the next encounter.

I have said that you differ from one another, that there are diversities of talent in all the men and men born into this wonderful world of ours. A few you may possess exceptional mental gifts ready to used apparently against all difficulties, and capable much development. I have known such individuals on whom fortune had cast many favours and as my duties. I remember several in my student days, en studying for the medical profession. My ex-

dience tells me now that they were not always the successful students, and their after careers in an instances belied woefully the promise of their youthful days. The less gifted man often overtakes the one who might easily win in the scholar's race; it is who plods, who never knows when he is beaten who is able to sharpen well his less brilliant talents.

It is the persistent worker who most frequently makes the successful student. There is hope therefore for you all, and success for you all, in propertio to your deserts and endowments.

Let nothing stand in the way that you can remove that will interfere with or retard your progress or your success as loyal students and well-equipped pharmacists. Do not be satisfied with the Minor diploma of your profession, but press forward to the Major qualification, and far beyond that if you have the opportunity.

If by chance, or rather as a result of well-directed study and a true student's ardour, you develop faculties to a degree that may carry you outside the confines of pharmacy, I do not think anyone need utter a complaint. We may hope that in these instances science may be the gainers if pharmacy appears to be the loser.

One of the most remarkable and instructive examples, clearly demonstrating to the world that nothing is gained by indolence and immaturity, and that nations, as well as individuals, demand and require cultivation if success in life be the aim. It is the conflict startling the nineteenth century and giving object lessons to Europe, between the lively little Japs and the heavy conservative Chinese. The Japanese, both rulers and people, believed in a "curriculum"; almost the entire nation went to school and learned the arts of both peace and war. They adopted modern ways and modern ideas of government, and both princes and people sent their young men to Europe to be trained in law, literature, science and handicrafts, as well as the most modern and refined methods of hateful war. The Chinese, although they established a system of competitive examination for filling of the Government appointments centuries ago, they examined each other in the obsolete and stereotyped knowledge of past ages. The nation as a whole, both rulers and people, remained immovable, and held themselves aloof from the influences of real culture and progress, scorning other nations as outside barbarians. They will be a mighty nation, for their numbers are almost countless, when they turn over in their sleep and wake up to assimilate modern ideas. I hope the war is nearly over, and that the Japanese may know when it is wise to cease hostilities, and once more return to cultivate the arts of peace, for the game of war is a costly game to play at.

It is another example of life's little ironies to learn that in the disinfection of Hong Kong during the recent visitation of the plague the chlorinated lime and sulphuric acid employed were imported from and manufactured in Japan, and they are described as being of excellent quality.

I wish, if you will allow me, to urge upon you the necessity of becoming careful and expert users of your hands, exact and patient manipulators and experimentalists. It is gratifying to find that you have a department in your Association devoted to re-
search work, and much may come out of it that is good and meritorious.

I have often thought that the handicraftsman, the expert worker in metal and other media, serves by example to teach us many a useful lesson. How marvellously trained some of them are, and how independent their labour makes them.

I daresay you are aware that the young men of the royal family of Prussia are trained in some kind of handicraft. I think the present Emperor, or was it the much lamented Emperor Frederick, became an expert worker in gold and silver. It is a great and good thing to have "an honest passion for perfect work." The Danish proverb runs thus: "A good handicraft rests on a golden foundation."

There is a most useful gift you all possess to a certain degree, though it may be a slumbering one in some of your minds, which I advise you to cultivate, as it brings with it both pleasure and profit, as well as the power of accurate observation. For this purpose carry with you always a small piece of lead pencil and a very small sketch book. I refer, of course, to the art of drawing correctly any object you may wish to impress upon your memory.

In the course of a very short time, if you cultivate this gift, you will be surprised and delighted at your progress in the graphic art. With a growing knowledge of what is called the value of line, which the use of your pencil will give, you will at length realise the glory of the sense of colour, as well as of form, in the objects presented to the eye, and, lastly, the love of the beautiful ever present in nature, be the objects great or microscopic. The wonder of the art served will be found, and when you have learnt to look upon nature with educated eyes she will become your most devoted friend, servant, teacher, and companion, ever present with you.

You will begin to think, perhaps, that I have wandered some distance away from the immediate object that is before us this evening; yet I have only given brief expression to a few time-worn ideas, which, I imagine, are quite relevant to this the opening night of another season of your Association. Not content only with the work you are doing at the School of Pharmacov, which brought you to this historic building, you are prepared to band yourselves together in a fraternal spirit that you may give encouragement to one another, as well as add to your stock of knowledge and experience. May I be allowed to express the hope that the new session will be in every way successful; that you will gather all the students of the school within your ranks, and that the old members of the school, wherever they may be, may recognise your efforts and join hands with you in usefulness and good comradeship.

When the session is over and you have stayed at No. 17, Bloomsbury Square, as long as circumstances permit you to remain, and you sally forth to undertake the various duties of the different careers opening out before you, you will not forget the friendship of your comrades and the loyal service due to pharmacy and to the Pharmaceutical Society. I heartily wish you each and all the certain success which follows real, honest work, and the happiness which comes to all who live useful and faithful lives.

To conclude, let me quote from a French writer, "The happiest of men were he who, understanding his craft and working intelligently with his hands, and earning competence and freedom by the exercise of his wits, found time to live by the brain and by the brain, to understand his own work, and to love the work of God."

At the conclusion of the address a vote of thanks was proposed by the Chairman,seconded by Mr. Joseph Innes, and carried by acclamation.

The election of officers was then proceeded with, Messrs. H. L. Lee and S. Bastow being appointed as scrutineers to count the voting papers with the Secretary. The result of the election was that Messrs. T. A. Henry and H. T. Durand were chosen as Vice-Presidents; Mr. F. W. Short as Secretary and Treasurer; Mr. C. S. Ellis as Assistant Secretary, and Messrs. H. Brown, S. Davis, J. R. Walker and J. G. Y. Stoddart on the Executive Committee.

The meeting then adjourned.

CHEMICAL SOCIETY.

A meeting was held on Thursday, November 15, its President, Dr. Armstrong, F.R.S., in the chair. The minutes of the former meeting were read and confirmed and the names of a number of candidates for election into the Society read, the arrangement adopted at the previous meeting being followed. Mr. A. E. Tames was formally admitted a Fellow of the Society. The President then called on Mr. Pope to give an account of work done on the haloid derivatives of camphor, himself and Mr. Kipping. When the derivatives of camphor containing the sulphon and haloid radicals heated, sulphur dioxide is given off and a haloid derivative left. In this manner several new haloid compounds were formed, such as chloro-, bromo-, chlorobisz, dibrom- and dichloro-camphor, by one of these reactions:

\[ C_6H_{10}O \cdot SO_3X + SO_3 = C_6H_4OX \cdot SO_3 \]

or

\[ C_6H_{10}O \cdot SO_3Y = C_6H_4OXY \cdot SO_3 \]

where X and Y stand for different halogens.

He briefly described these bodies, some of which exhibited curious properties, e.g., existing in different crystalline form, and exhibiting stereoisomerism.

Dr. Armstrong then called on Dr. Parkin, F.R.S., who—though not often seen at Burlington House—is well known to all chemists on account of his masterly researches on trimethylene and its homologues, to give some account of his recent work on this subject.

Dr. Parkin first gave an account of the preparations of certain compounds used in the study of these derivatives, and then gave in a very clear and lucid manner some reasons for viewing these bodies as ring compounds. In favour of this view he adduced the fact that the ring was easily broken by hydrogen bromide in trimethylene compounds, less so in tetrachloroethylene, and not at all in the pentamethylene group.

This fact is in accord with theoretical considerations deduced from the linking of the carbon atoms in the molecule if their affinities are exerted toward the corners of a tetrahedron as stated by Le Bel and Van Toff.

He also gave a description of the existence of two isomeric forms of ortho-hexahydrotoluol and 1,2-\(C_6H_{15}CH_2COOH\), which isomerism is probably similar to that of furmaric and maleic acids, being so-called cis- and trans-modifications. The last part
PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.

LIST OF DONATIONS.

At the last committees meeting of this Association, the Secretary, Mr. James Cocks, announced the receipt of the following donations:—Five cases of specimens, from Messrs. Jackson and Co., Plymouth; original prescriptions, from Mr. Walter Hills, Messrs. Corbyn and Co., and Messrs. Wilcox and Co.; two specimens crystals in glass vases and Lecher's "Materia Medica," from Messrs. Evans, Lecher, and Webb; Ganot's "Physiol.," "Dispensatory, U.S.A.," "Antiseptic Treatment of Wounds" (Cheyne), "Commercial Handbook of Chemical Analysis" (Norman), Royle's "Materia Medica," Leonard and Charty's "Dictionary of Materia Medica," from Mr. H. J. Dalgleish (Messrs. Ford, Shaftland, and Co.); musk pod, from Mr. C. J. Park; "Materia Medica" and two habitat maps, from Mr. G. S. V. Willis.

JUNIOR SECTION.

A smoking concert in connection with the above was held at "The Farley Hotel," on Wednesday, November 21, the chair being taken by Mr. C. T. Weary at 7.30 p.m., and the majority of the members of the senior section being present. A most enjoyable evening was spent, the programme reflecting great credit on the committee (Messrs. Goodwin, E. H. Newman, H. O. Westcott, and C. Wood). The following gentlemen took part in the proceedings:—Messrs. J. D. Newnay, T. C. Weary, Barker, J. E. Bone, Mash, White, E. H. Newman, H. O. Westcott, C. Wood, J. H. Bailey, A. Barber, G. Keast, Yeo, Morgan, R. F. Roper, and Harris. The balance remaining after payment of expenses, together with a collection made in the room, was forwarded to the Benevolent Fund.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

At a meeting held on November 9, Mr. A. Sidney Campkin, M.F.S., J.P., being in the chair, and a good number of members being present, Mr. A. Ivatt, M.A., of Christ's College, and lecturer in Pharmaceutical Chemistry in the University, gave a paper, of which the following is an abstract:

SOME DISPENSING ERRORS.

BY A. IVATT, M.A.

The errors to which dispensers are liable may be divided into two main classes; first, those in connection with the prescription itself, and, secondly, those which occur whilst compounding the medicine.

Every dispenser before compounding a prescription should feel certain that he understands the physician's intentions, and, also, the dispenser is in error if he fails to detect a mistake of the prescriber, such as the writing of the sign $3$ instead of $5$. It is, perhaps, needless to point out that bad writing and contractions on the label should in all cases be avoided. The dates of prescriptions should be noted, as many still in use in old families were written in the time of the Ph. Lond. For instance, liq. morph. of the B.P. contains only half the amount of morphine of the Ph. Lond. preparation.

In considering the second class of errors, Mr. Ivatt strongly urged that inorganic substances be chemically tested and organic substances carefully examined before being placed into stock from the wholesale houses. He also spoke of the liability of giving a larger dose of the drug than is intended, e.g., Liq. strychnine crystallises on the lip of the bottle, and the alkaloid is liable to come away with the liquid.
when measured if the bottle is not first wiped; while, on the other hand, a very small, or even useless, dose may be given by want of attention to the keeping of drugs, for instance, ac. hydrocyan., ac. sulphur., and ferr. redact. The lecturer also spoke of other errors one is liable to fall into, such as the use of the avoirdupois instead of troy ounce, improperly balanced scales, the measurement of minims of potent liquids, the imperfect graduation of bottles, etc.

In conclusion, he pointed out that to avoid great errors it is important to take care to avoid small ones. Arrangements of bottles, systems of checking, and mechanical appliances do much, but will not prevent the careless or ignorant from falling into error; but he who continually strives to add to his stock of knowledge and is habitually precise in small matters, does as much as lies in the power of any human being to avoid the errors to which dispensers are most liable.

A very interesting discussion followed, in which several members joined, giving some of their own experiences and instances which had come under their notice.

After the usual votes of thanks the proceedings terminated.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The first monthly meeting of the session was held in the Society's rooms, New Surrey Street, on Wednesday, November 14. The President, Mr. J. F. Earley, occupied the chair, there being a good attendance of Members and Associates. After the transaction of some preliminary business, Mr. Ibbitt read a paper, of which the following is a very brief abstract:

RAMBLES ROUND SHEFFIELD.
BY H. R. IBBITT.

Commencing with the geological formation of the district, reference was next made to the many pieces of woodland which are, to all appearance, remains of the primeval forest which once covered all the lower valleys of the Don and its tributaries, and to the moors, which, though much curtained by the advance of cultivation, still occupy extensive tracts of country.

The various features and points of interest in the valleys of the Don, Loxley, Rivelin, Porter, and Sheaf and of the hills which rise between them were described, as well as more extended walks. Interesting legends in connection with many of the places were narrated, and, in conclusion, reference was made to the variety of the botanical specimens to be obtained in this most interesting and attractive neighbourhood.

At the conclusion of the paper a long discussion took place on the subject, in which Messrs. Austin, Ellinor, Hewitt, Marshall, Newholmes, and others took part, after which a vote of thanks was passed to Mr. Ibbitt for his interesting paper.

SHEFFIELD MICROSCOPIcal SOCIETY.

The first general meeting of the above Society was held on Friday, November 16, in the Rutland Institute, Fargate. The Rev. T. S. King, F.G.S., F.R.M.S., occupied the chair. The Hon. Secretary (Mr. Newholmes) read the report of the last session, which showed the Society to be in a most flourishing condition. Much real and lasting work is being done by this Society, and the members (now numbering over one hundred) are entering on the new session with fresh zeal for microsc. ends.

The inaugural address was then read by Dr. Hall M.A., M.R.C.P., who, in a concise and interesting way, proceeded to deal with the five special senses found in mankind, dwelling at some length on the sense of sight. It was encouraging, he said, to see such a goodly number congregated together who took such a lively interest in microscopic work.

On the motion of Mr. C. O. Morrison, seconded by Mr. Jenkins, a hearty vote of thanks was accorded to Dr. Hall for his most valuable address.

A ballot took place, and four gentlemen were elected to membership.

SCOTTISH TRANSACTIONS.

EDINBURGH CHEMISTS' ASSISTANTS' AND APPRENTICES' ASSOCIATION.

The opening meeting of the 17th session was held in the Pharmaceutical Society's House, 36, York Place, Edinburgh, on Wednesday, November 14, at 9.15 p.m., Alexander Sutherland, President, in the chair, and there was a large attendance.

The minutes of last meeting were read and approved, and several apologies for absence were intimated.

The Secretary then read the report on the Association Prizes' Competition. Six candidates had entered, and the prizes were awarded as follows:—First Prize (a prize ticket for Dr. Stevenson Macadam's Lectures on Chemistry) to John Harris Burns, 73, Princes Street, with 80 per cent. marks; Second Prize (British Pharmacopoeia and Gerrard's Materia Medica) to Alexander Mackenzie, 139, Princes Street, with 78 per cent. of marks; Third Prize (Richter's Inorganic Chemistry) to William Francis Martin, 21, Duke Street, with 76 per cent. of marks.

The prizes were then presented to the successful competitors by Mr. John Nesbit, Portobello, Chairman of the Board of Examiners for Scotland. Mr. Nesbit congratulated the prizemen on their success, and said the non-successful entrants might also be satisfied that although they had not got a prize, they had gained what was perhaps better: an amount of knowledge that would be of permanent value. He took occasion to refer to several of the former prizemen who had distinguished themselves, and now filled important appointments in various parts of the world.

On the motion of the President, a very hearty vote of thanks was awarded to Mr. Nesbit for his kindness in attending to present the prizes.

The President then proceeded to deliver the following address:—

INAGURAL ADDRESS.
BY ALEXANDER SUTHERLAND.

At the beginning of a new session it is customary to note the errors and failures which have marred our course in the past, and to map out our road for the future. Consequently, about this time every year numerous guides appear, each with his plan of "setting on," and, were the "Pharmacist's Progress" written, it would be evident that there are as many by-paths and enchanted grounds to be met with, as those described by the immortal dreamer of Bedford.

Now I am not going to play the guide in that way but I would like you to note some of the relations of the pharmacist in his progress, and in the first place, to have a glance at the pharmacist himself. The basis of the personality of the pharmacist is character. How rarely do we find this inoculated on our young men! On every side we hear—"attend our..."
go through our curriculum," "study my work," but rarely "first cultivate honesty, integrity, reverence, general uprightness of character." Now a knowledge of right and wrong does not constitute character. Character is formed by doing these things, and doing them habitually. The youthful aspirant to pharmacy usually has only the knowledge of right and wrong when he makes his first acquaintance with the ever-present pill-machine and the perennial sedatives powder. His character will be formed by what, whether of good or evil, he is allowed or set to do: but more especially by what he sees done—In other words, by the result of the characters of those around him.

It is quite a common thing to hear the following remark: "Oh! I believe Mr. B. is a little wild outside, but I have nothing to do with that." Nothing? gentlemen, nothing? You know that Mr. B. has a painful habit of exaggerating outside, but of course you believe Mr. B. implicitly in business! Do you? The illustration might be extended. You who are seniors and employers should realise that when you have young men in your hands for more than two-thirds of their waking time, during the most impressionable part of their lives, for, say, an average period of six years, you possess the greatest influence on them, and that you exercise that influence for the best: for the formation of a reverent, upright manliness, which will make their acquired knowledge available in the highest degree for the safety and health of the public. Not realising this, you may be cursed by these young men both in their hearts and by their actions. I am afraid some of these actions are proving curses to you now.

You grumble because your assistant transferred his services to another firm for which you call a "peltry advance" of $10 per annum. You say you would not mind that, but, when leaving, your assistant told you he was leaving in order to study. Just so. Your assistant one day heard you explain to a customer the difference in the price of Liebig's Extract in your establishment and the price in the grocer's round the corner by the slight suggestion that yours was genuine.

Again, we hear you grumble at the young men who make "stores" possible. You have, to a large extent, formed the character of those young men. Does it not do much for the influences exercised, when young men trained by you in habits of thought to a large extent as well as of work go to serve those to whom you are imitable and who are imitable to you? Young men do not always go to stores because they are unfit for any other place, or because no other place would take them or was open to them. They and we have worked at the same counter and been lectured and instructed by the same "boss." They and we have seen the said "boss" agaze out of the door to see if Mr. Over-the-way was closing before there was any signs of our shutters being put up, the while he spoke of the hard-worked and late-worked pharmacist and the excellence of the early closing movement (for other people). They and we have known the same "boss" drop the price of sundries all round on the authority of some "traveller's tale"—"town-traveller's" tale, I should say—about some place where sweeping reductions, in some things, were being made, and have suffered for it in low salaries, due, according to the "boss" to the general depression in trade. They and we are older now. They have gone to the "stores" for, in many cases, as good salaries, and in the majority of cases shorter and more fixed hours, and, feeling comfortable, they speak of our cant and hypocrisy, and knowing our ways they challenge us to throw stones at them, and we dare not.

We cry with an exceeding bitter cry for an ethical code embodying an upright, gentlemanly treatment of one another. If we wish ever to see it realised, we had better begin to realise it in ourselves, so that we may be able to form it as a portion of the characters of those in contact with us.

Now, from these remarks I think you will gather my first point, that the formation of an honourable character is the laying of the foundation on which should be built the pharmacist's life, and that this character, if formed, would simplify the burning questions of the day. The application of course is, that you begin and cultivate your characters and the characters of those in contact with you.

Along with the development of character comes education and the acquirement of knowledge. The appointed tests of education are examinations. These should be satisfactory tests of things essentially needful. The present tendency, I think, is rather to overdo the number of things supposed to be needful, as witness the tendency to improve on the "Preliminary." Take the language question, for example. As auxiliaries one might learn Greek, on account of its place in scientific nomenclature, and not only French and German for scientific literature, but Russian, Danish and Italian, to go no further.

The examinations are for the pharmacist, and not merely for the chemical specialist or bibliographer, and when a lad knows his arithmetic well, his own language thoroughly, and can translate with facility from and into the one language with which he comes in contact, I do not see that his burdens should be added to.

After the "Preliminary" comes the special pharmaceutical education. Now we hear a great deal regarding the necessity for a curriculum, and I doubt not but that it would do a great deal of good, but even already it is, to a large extent, merely a cloak to cover the sins of an inefficient apprenticeship. An apprentice learns to manipulate a pill-machine, to make a mixture in a fair way, and other pharmaceutical processes. Has he not as much right to learn how to test the drug passing through his hands, and to have their properties, chemical or otherwise, explained to him? A curriculum will be useful, in fact is almost requisite for the codification of his knowledge, but not as a substitute for the training he ought to have in the shop. To recapitulate: the pharmacist must be a man of character, with a thorough knowledge of things necessary and essential, and be adding steadily to his store of auxiliary knowledge. So much for the pharmacist himself.

Now let us consider the pharmacist's relations to his fellow-craftsmen. These, we all regret, are not of the best. "Why are we so jealous of each other, and why
do we stand aloof from one another so?" I am afraid that is a conundrum we must all give up! The ready ear for any scandal affecting another, the disposition to be little one another disgraces us. We are certainly greatly characterized by "the faithless coldness of the times." In the Confucian "Analogy," a favourite antithesis is that between the princely man and the small man. In many of our acts of social intercourse we are, I am afraid, rather of the nature of the small man. We must cultivate the character of the princely man, with nothing mean and small about us. Take, as an instance of the small spirit, the attitude of many men towards the Pharmaceutical Society. It puts one in mind of the description of the "mixed multitude" who inhabited part of Palestine at one time, and of whom it is recorded that they feared the Lord and served their own gods, for these men fear the Pharmaceutical Society, but serve local federations or any other society interest. We must learn to be loyal to our own society first, and influence those around us to be the same.

But the pharmacist has a wider relationship yet—his relation to the State as a citizen and as a pharmacist. As a pharmacist he does the State good service whether he be master or servant in the pharmacy, but he also has a social relation to the State, and if by long hours—which cause enfeeblement of body, curtail reasonable relaxation, or render social duties and ties impossible—he damages either himself or others in their relation to the State as citizens, he is a criminal, constitutes a public danger, and justifies State interference.

Now, what I am about to say further to you will probably make you smile, but do not laugh too much; beneath the humour there is a very serious vein, which it will be worth your while to look into. As an assistant the pharmacist is a wage-earner, and it is a maxim that the minimum wages of a respectable citizen should be sufficient to enable him to live and reproduce his kind in comfort. The science of the State informs you that your physical manhood reaches its fullest development towards the age of 25, but how few of you at the age of 25 receive enough to keep yourselves in comfort, let alone a wife and family; so you toil on for about ten years more, and then, finding you have at last got a pharmacy of your own, you, old and cranky, with the joyousness of youth all gone, "settle down."

I place our wages system at the bar of our opinion, and in the name of struggling juniors who can hardly keep body and soul together, of seniors who have to toil for ten to fifteen years to save sufficient to buy a fifth-rate pharmacy. Yes, and in the name of pharmacists who are employers, and who suffer through the multiplication of pharmacists, I condemn it as bad. Many an assistant opens a pharmacy of his own because he was too poorly paid as an assistant, and because there was no chance of his settling down in life, so that the short-sighted employer suffers from the results of his short-sightedness. I would like to see it reckoned just as honourable for a man to remain as an assistant, and fulfil his duties as a citizen in that capacity on a sufficient salary, as it is for him to wait

"before he settles down until he opens a pharmacy of his own—only, in many cases, to increase the general misery.

I have now indicated some of the stumbling blocks in the pharmacist's progress. Your own good sense will point out the course to pursue. If you cultivate an honourable character, a sound knowledge of things necessary and essential, combined with an ever-growing and ever-widening knowledge of auxiliary things, not forgetting the words of the poet:

"Let knowledge grow until it looks more to more,

But more of reverence in us dwell."

Mr. J. M. Cameron, the Vice-President, in moving a vote of thanks to the President, said they were greatly indebted to him for the frankness and candor with which he had spoken on important topics that well deserved serious consideration. Whatever might be thought of his suggestions, there would be but one opinion as to the laudable end he had in view. He had pointed out undoubted shortcomings, and indicated the remedial steps to be adopted for their removal.

Mr. Bos, President of the Edinburgh District Chemists' Trade Association, in seconding the vote of thanks, said he had listened with pleasure to the scholarly address which had just been delivered. It was eminently practical, and rather out of the usual line of addresses. He agreed with much of what was said, though on some points he was not so clear. With regard to the testing of drugs, for instance, he was not without hope that such would be time be part of an apprentice's training, but they had to defer to custom, and this would only come about gradually. With regard to the relationship subsisting between members of the pharmaceutical craft, he delighted to observe that during recent years there had been a very marked improvement. He could remember a time in Edinburgh when there was nothing like the "come and go" that now happily prevailed. He was in hopes that such a happiness would soon be established. He did not mean an unethical code, but a good understanding and mutual respect that would preserve them from running another down. With regard to shorter hours and adequate salaries, much consideration was required. What with out prices and keen competition he did not think employers were in a position at present to pay a salary to assistants such as the President had indicated.

Mr. Nesbit said he concurred in the views expressed by Mr. Bos. He had frequently observed the assistants who most clamorously asked for shorter hours were themselves the greatest sinners when they started business for themselves. He did not agree with the view that the Preliminary examination should be increased in stringency and scope. He also had the opinion that they should have a compulsory curriculum, for they could not teach an apprentice chemistry, botany, materia medica. He was in favor of attend a school, and then he would pass his examinations with credit. He had to congratulate the Association on the very able address they had just listened to.

Mr. Luman said he felt as if he were being arraigned and taken to task. They, as employers, were in good intentions, but soon found the struggle to make a profitable business predominate in their e
The President had put his case well, and, not suggesting invidious comparisons, he thought it must have been more than a coincidence that they listened to it in the history of the Association.

As said he would like to reaffirm the views of the President, had expressed in favour of a higher bond in the "Preliminary," and a compulsory curtailment of the time. On these points he was inclined to differ from the President, but he concurred most heartily in the desirability that the President, in replying, said he did not oppose call for an improved "Preliminary." What was it should contain certain essential knowledge and what was only auxiliary. In regard to the knowledge he was in favour of it, but it must not be the place of, or become a substitute for, a proper partnership. He concluded by thanking the gentlemen who had kindly favoured them with their presence at the opening meeting, and expressed the hope that they would honour them with their presence during the session.

GOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

The usual fortnightly meeting was held on Thursday, the 15th inst., when Mr. John Foster, vice-president, of the Scotch Association, occupied the chair, and introduced Professor King of Anderson College Medical School, who delivered a lecture on "The Early History of Botany." At the conclusion of the lecture, Dr. James Brown moved a vote of thanks, which was seconded by Robert Brodie, and supported by the chairman, who referred to the pleasant botanical rambles he had enjoyed under Professor King’s guidance. The motion carried unanimously.

COUNCIL MEETING.

Towards a council meeting was held, at which a minute was addressed to the president of the Association Mr. M. Carteigh, president of the Pharmacetical Society, stating his desire to meet the Glasgow West of Scotland Association on Wednesday, November 28, was read and considered. It was agreed to hold the meeting in the Christian Institute, Buchanan Street, notice thereof to be given to chemists and druggists throughout the West of Scotland, and every effort made to have a representative gathering. The temporary secretary informed Mr. John McMillan had offered to present the Association with a framed portrait of Mr. Alexander Kinninmack. The offer was accepted with acclamation, and secretary instructed to convey the thanks of the solicitor to the donor in writing. The meeting adjourned for the 29th inst, was postponed to the following Thursday, December 6.

parliamentary Law Proceedings.

PROCEEDINGS UNDER THE MEDICINE STAMP DUTY ACTS.

SALE OF MEDICINES UNESTAMPED.

November 14, Mr. Bishop, chemist, of High Street, Kincardine, was summoned, before Mr. Lane at the Police Court, at the instance of the authorities, for selling a proprietary medicine without stamp. Mr. Hawkins prosecuted, and stated that Act 52 George III., cap. 150, sec. 2, laid down all patent and proprietary medicines which were by public advertisement must bear an Inland Tax stamp. In this case the defendant sold a preparation which he called "Aromatic iron and quinine tonic." On the label on the bottle it was stated that the medicine was made by Mr. Hawkins, chemist, 129, High Street, Kincardine, and if the case ended there he (Mr. Hawkins) would not have suggested that the prosecution should have been undertaken. In his shop window, however, was a tablet, on which was written "Bishop’s Iron and Quinine Tonic." This Mr. Hawkins said implied that the tonic was a proprietary medicine, and consequently liable to stamp duty. The defendant said that the tablet complained of had been in the window for 16 years. Twelve years ago witness had a similar label on the bottle, but being informed that he was liable to stamp duty for selling the medicine in this way he altered the label to the present form. He had not, however, removed the ticket from the window. Mr. Lane held that this ticket was an advertisement within the meaning of the Act, and it made the medicine liable to duty. It was, however, a technical offence, and if the defendant removed the objectionable ticket he should only fine him 5s., with 2s. costs. The defendant said the ticket was removed as soon as he received notice.—Morning Advertiser.
son said seidlitz powders were often prescribed, and it
was important that they should contain the proper
ingredients and quantities. Alderman Brigg: That is
a matter between you and your employers. We shall
not give you costs. Mr. Randerson: You will allow
the Court fees? Alderman Brigg: Nothing beyond
that.—Bradford Observer.

POISONING CASES AND INQUESTS.

POISONING BY AMMONIA.
Emily Taylor, aged 20, died at Dewsbury on Sunday,
November 11, after drinking liquid ammonia. Verdict:
"Death was due to taking ammonia while temporarily insane."—Bradford Observer.

DEATH FROM OVIRDOSI DE LAUDANUM.
Mrs. Thorne, aged 65, of Friars' Place, Moulsham,
died on Sunday, November 4, from the effects of an
overdose of laudanum, administered in a mixture con-
taining treacle and vinegar. Verdict: "Death through
inadvertence."—Essex County Chronicle.

CARBONIC ACID POISONING.
Thomas Cowley, picture-frame maker, of Clare
Street, Liverpool, died on Wednesday, November 14,
from the effects of carbonic acid self-administered.—
Liverpool Mercury.

SULPHURIC ACID POISONING.
Robert Whitworth, aged 47, died at Bowling Dyke
on Saturday, November 3, after drinking sulphuric
acid. Verdict: "Suicide whilst of unsound mind."—
Halifax Advertiser.

POISONED BY A MORPHINE PILL.
Nancy Bigbie, aged 14 months, died at Fleetwood on
Saturday, November 10, after swallowing a quarter-
grain morphine pill, of which she had in some way
got hold. Verdict: "Death from misadventure."—
Fleetwood Express.

POISONING BY STRYCHNINE.
Theresa Less, aged 25, of Brick Lane, Bethnal
Green, died on Tuesday, November 13, from the effects
of rat poison containing strychnine. Verdict: "Suicide
whilst of unsound mind."—Daily Telegraph.

POISONING BY PRUSSIC ACID.
Lance-Sergt. Richard M. Eager, dispenser at the
Royal Marine Infirmary, Stonehouse, died on Thursday,
November 15, as the result of prussic acid poison-
ing. Verdict: "Death by misadventure through
taking an overdose of prussic acid medicinally."—

Reviews and Notices of Books.

THE PHARMACOPEIA OF THE LONDON HOSPITAL
Compiled under the direction of a Committee
pointed out by the London Hospital Medical Co.
In the latest edition, recently published, of this
Pharmacopoeia there is a "Materia Medica," together
a collection of formulae, an appendix comprising
structions for case-taking, directions for the
amination of urine, a table of doses, etc. 
raison d'être of the "Materia Medica" is not to be
obvious. There is a note at the beginning, to the
following effect:—"All the drugs of the B.P. of
course, kept in stock; they have been omitted
from this Materia Medica, except where prepara-
tions of them are made special to the London Hospital
also the Posological Table at the end of the Phar-
macopoeia." The descriptions of the articles mentions
too meagre to be of any use, and the
omitting having an account of the most important
drug, those the compilers deem so—in a handy for
therefore, without advantage. Among the
mule, over fifty have names identical with
preparations occurring in the British Pha-
coopoea, but are of different composition. Th
of this ought to be apparent to anyone
medical or pharmaceutical knowledge, and can
be too heavily censured. Hypodermic inject-
morphine, liniment of opium, and pill of less
opium, for example, differ in strength from
ordered in the British Pharmacopoeia. Many others
are preparations of considerable import and
the compilers of the London Hospital
Pharmacopoea must be held responsible for a proc
calculated to destroy that uniformity of
and other properties which the publication a
British Pharmacopoeia was intended to pr
throughout the United Kingdom. If the compiler
the London Hospital Pharmacopoea disapp
any of the official remedies, the onus rests with
or devise names for their alternative formul
shall prevent the conclusion likely to result
having preparations synonymous with the
B.P., but of different composition.
There are no less than 124 formula
mixtures, 68 for pills, and 53 for oint.
It may be safely said specified in this
that the prescriber will not remember an
student will not trouble to learn the composit
so many formulae; and the dispenser cannot
advantage, have ready prepared such a 
stock remedies, many of which contain such 
hydrocyanic acid, frogs, and perchloric e
cury, and will not keep good more than a

Correspondence.

The Metric System and the First Examination.

Sir,—It is not desirable that one who exercises the sub-judicial functions of an examiner should often invade the domain of pharmaceutical politics, and it is my practice, in common with that of my colleagues, to avoid the rea whose the strife of tongue and pen may at times assume an unseemly. But occasionally a question arises where word from an "insider" may cause our fellow-members to estimate before passing a hasty judgment upon the doings of the Board. I do not wish to mention the name of the Manchester address of Mr. Rymer Young. For its purpose it could not readily be improved upon. Gracefully rife, the opinions expressed are always calm and sincere in tone. In dealing even with matters of considerable controversy, Mr. Young never fails to maintain a dignified language expected from a leader of English pharmacy. With the subject matter of a large portion of his address I feel myself in genuine sympathy, but it is hard to persuade me for saying that such is not the case with regard to his remarks on the "Metric System." Mr. Young observes: "I should like to remind you that Mr. Goodwin considers the Board ought not to be content with a merely theoretical knowledge of the metrical system of weights and measures, but that candidates should be required to show practical familiarity with their use." A resolution to this effect was passed by the Council, but few years later. The inference is drawn from this, and from the further examination, that the Board does not require a practical, but merely a theoretical knowledge of the metric system. As a matter of fact, such is not the case, and the practical examination deals more with the candidates, especially in the subject of the more familiar. During the minor and major examinations in Practical Chemistry, the measurement of weights and measures is made use of in determining specific gravity. It is well-nigh impossible to keep a ready memory of the formulas for dispensing; and if by chance you do manage to combine a formula, the very next day, out of sheer "easedness" perhaps, the dose will be altered and your pains thrown away. So much for the Hospital system. Perhaps there may be an evil, but it is necessary to state the case as the Board desires. With regard to the act of prescribing, I do not think it is in the out-patients' room that students are expected to, or do, get their insight into that art, but rather at the bedside of the sick, under the guidance of the clinical instructor. I have seen that the Board is not of the necessity of dispensing in the study at the minor subject, nor the preparing, dosing, or dispensing in the practical subject. I think that the Board is unwilling to limit to such an extent as he must necessarily be done, and that the patient has to the present system of dispensing. I believe, but I think a good many will agree with me that if we had one per cent, less items to deal with in our dispensatories, suffering humanity would be none the better off, and I cannot understand the man who says that the less is more. The Board is a good one, and I think the Board is a good one. What do you say?—Use the old remedies well and judiciously, and you will have no need to puzzle your brains to find new ones.

Dispensary City of London Hospital for Diseases of the Chest, and Divisional Secretary for N.B. Bethnal Green.

A Correction.

Sir,—I beg to call your attention to an error in last week's Journal, page 410, where you mention Mr. Brooks as having taken part in the discussion on Mr. Yorke's paper. My name ought to have been inserted there; the mistake may have arisen from the fact that I am in business with Mr. Brooks. Will you kindly rectify in the Journal for the current week.

Weaste.

JAMES PENDBURY.

HOSPITAL PHARMACOPEIAS AND PRESCRIBING.

Sir,—Your editorial on the act of prescribing in last week's issue of the Journal, attributing to some extent the decline of that art to the existence of hospital pharmacopoeias, calls for some little notice in defence of their use, for without them it would be a matter of impossibility to carry on the work of a large hospital dispensary, however numerous the staff might be. But if I am 'one of those who are used to the routine of the Board,' I would say that their use is more often honoured in the breach than in the observance. I grant that there are no such things as uniformity of dosage, the range of each man's views in regard to dosing being very different, and so a slavish adherence to a set of formulas is not thought of by the Board. It may be, or more commonly into use. Your remarks regarding hospital prescribing would years ago have been quite justified, but my experience—and it extends over many years—is that now there is a very great independent (if I may use the word) prescribing than formerly. It is no uncommon thing to have a prescription with five, six, or seven different ingredients in varying doses; in such cases it is well-nigh impossible to keep a ready memory of the formulas for dispensing; and if by chance you do manage to combine a formula, the very next day, out of sheer "easedness" perhaps, the dose will be altered and your pains thrown away. So much for the Hospital system. Perhaps there may be an evil, but it is necessary to state the case as the Board desires. With regard to the act of prescribing, I do not think it is in the out-patients' room that students are expected to, or do, get their insight into that art, but rather at the bedside of the sick, under the guidance of the clinical instructor. I have seen that the Board is not of the necessity of dispensing in the study at the minor subject, nor the preparing, dosing, or dispensing in the practical subject. I think that the Board is unwilling to limit to such an extent as he must necessarily be done, and that the patient has to the present system of dispensing. I believe, but I think a good many will agree with me that if we had one per cent, less items to deal with in our dispensatories, suffering humanity would be none the better off, and I cannot understand the man who says that the less is more. The Board is a good one, and I think the Board is a good one. What do you say?—Use the old remedies well and judiciously, and you will have no need to puzzle your brains to find new ones.

Dispensary City of London Hospital for Diseases of the Chest, and Divisional Secretary for N.B. Bethnal Green.
CHEMISTS AND COMPAHIES.

Sir,—I think the question of unqualified company trading ought to be discussed in the Journal, with the object of coming to some understanding as to the future position of the chemist. It seems, as the law now stands, that there are two parties who are allowed to carry on business under the name of chemist and druggist: viz., the individual on the one hand who must pass the examinations of the Pharmaceutical Society, and on the other hand the company of seven individuals, not one of whom need be a qualified chemist. Owing to the keen competition introduced by these companies, the business of the chemist is becoming more and more unprofitable, and men will not care to enter the ranks of chemists and druggists unless they see a prospect of fair reward for their labour. It is to be hoped there will be the chemists already for the needs of the population, and that some limitation is necessary; but if so, should not the competition which is to bring it about be upon fair lines? Qualified man against qualified man, not against a company of unqualified capitalists. Complaint is made that so many chemists do not support the Pharmaceutical Society. How can that be expected if the Society cannot protect the interests of its examiners? To some extent the Society is doing good work in prosecuting unqualified individual traders, but the most important work remains to be done. The inability of the Society to stop the carrying on of chemists' business by unqualified companies is much to be deplored. The company traders are now competing with individual chemists all over the country, and it may be that there will be few, if any, qualified men in the future able to get a living except by seeking company employment. It is to be hoped that the Law and Parliamentary Committee of the Council will give matter its earnest consideration, and take prompt action. One need hardly say that in the prosperity of its members lies the welfare of the Pharmaceutical Society.

PHARMACEUTICAL CHEMIST.

MEETING AT MANCHESTER.

Sir,—In what I believe to be an otherwise an excellent report of our Manchester meeting last week I am made to say (folio 410, line 31) that "the Society could be doing no more for the trade to-day than it was doing when those gentlemen left." As this is so opposite to what I did say and believe, will you kindly allow me to correct it. My answer to the gentlemen referred to was that the Society could not be accused of doing nothing for the trade to-day whatever may have been the case when they severed their connection with it. It may be interesting to you and your readers to know, as it is a pleasure to me to record, that both of these old friends have consented to join again. I notice you describe me as "Secretary." This should be "local secretary," and I am in just the same position as before. "Mr. Blackburn," who fulfils the duties of that office in connection with our Association, I must disclaim the honour.

Manchester. HARRY KEMP.

MANDALL'S PATENT (6179, of 1898).

Sir,—In the report in your issue of 3rd inst. of the proceedings for revocation of this patent you twice refer to the medicine in question as "lycine." The article in question is not so described either in the specification or patent, and as a matter of fact is different to that which has hitherto been sold by Mr. Mandall under the name of "lycine." We shall be obliged by your making this correction, which is of importance to our client.

Nevill and Beck, Solicitors for Mr. Mandall.

SMART DISPENSING.

Sir,—I received enclosed this morning from an A.P.S., and hope that it may stimulate by its smartness some of the younger fry among us.

Prater.

[Enclosure.]

"On coming home from church this morning, I found a prescription waiting for a M. and Pn. xx. The M. had in it 11/14. tr. ferri muriatis, Ph. Edin., and the powders were gr. vi. of pulver. sabine. The afternoon was spent in making the tint, and in hunting for the savin in the nursery gardens, etc. I found the latter, dried it, made the pulv. into some cachets, sent them off, and went to church again at 6.3."
THE MONTH.

Although pyrogallic acid is a powerful poison the bismuth salt does not appear to be so toxic. It is, therefore, been introduced as a disinfectant. J. B. von Winkel prepares it by dissolving 150 parts of pyrogallic acid in 650 parts of a 26 per cent. diam chloride solution, and adding this solution 316 parts of bismuth trichloride dissolved in 60 parts of a salt solution of the same strength. After digesting the water-bath for half an hour a solution is poured into water, and the basic salt then precipitated with sodium chloride until it has crystallized. The salt has the formula \( \text{Bi}_2(\text{OH})_2\cdot\text{O}_2\cdot\text{Bi(OH)}_2 \). Vincenzo Vittorio obtained similar salt by triturating pyrogallic acid with ice to its weight of bismuth carbonate and water. After heating the mixture on the water-bath one carboxylic acid ceases to be evolved. The process changes from white to yellow and is finally washed with water. Vittorio speaks highly its value as an internal antiseptic (Apotheke Pharm., ii., 657).

Preparation of Phosphine. The old method of preparing phosphine by treating phosphorus with caustic potash, is open to many objections, and Retgers claims to have discovered a simpler and more instructive method. This is based on the fact that phosphorus abines, under suitable conditions, with free hydrogen. The hydrogen is gently passed over phosphorus heated in a glass tube; the liquid hydrogen is condensed in a wash-bottle; phosphine gas free from hydrogen escapes into air (Jarem. Chir., vii., 254).

The difficulties presented by the preparation of pure phosphine are well shown by the experiments of Herrn shans and Heydweiler, described in Wiedew's Annalen. They noticed a surprising change between the electrical conductivity of Mr. distilled in air and in vacuo, the former being about fifteen times the conductivity of the latter. Even when water was distilled in vacuo, the conductivity was still influenced by the solvent on the glass containing vessel, but was to a great extent overcome by the use of less vessel in which water had been kept for ten years, so that the bulk of the more soluble constituents had probably been removed. Conductivity varied largely with alterations of pressure, being over ten times as much at 50°C. as at 0°C., and it was found that there was a temporary increase of conductivity when the current passed for any considerable time; an increase sometimes measured to 100 per cent. and not yet explained. The conductivity was only about 1/40,000,000,000,000 of pure water; the amount of residual conductivity in the water distilled in vacuo was estimated at only a few thousandths of a millimetre per litre, i.e., only one tenth thousandth as the weight of the air absorbed on exposure to atmosphere. This small amount of impurities still enough to increase the conduct to an extent which is estimated at about 0.1 cent.

J. Martenssen describes this substance as possessing good though Boroformate, mild antiseptic and astrignent properties. It has recently been successfully used in the Oldenburg Children's Hospital at St. Petersburg, and is obtained by saturating a solution of two parts formio acid and one part of boric acid in six or seven parts of water, with freshly precipitated and well washed alumina. The solution may be used direct, or may be concentrated until the salt crystallizes out in large scales of pearly lustre. The crystals dissolve slowly but completely in water or dilute alcohol, and the solution has an acid reaction and a sweet, astrignent taste. The alumins cannot be separated from the compound by the ordinary precipitants.

Oxiation of Alcohols. F. Gaud gives the results of experiments in which different alcohols were oxidized by Fehling's solution. In the case of ethyl alcohol a mixture of equal parts of the fluids was decolorized in about an hour, a crystalline precipitate formed, and the liquid was found to contain unaltered alcohol, aldehyde, and acetic acid under the form of potassium acetate. The reaction is similar with methy alcohol, formic acid, and potassium formate being formed; whilst propyl alcohol yielded propionic aldehyde and potassium propionate. In a second series of experiments an excess of Fehling's solution and elevation of temperature modified the results, cupric acetate being formed with ethyl alcohol, and decomposing into cuprous oxide and carbonic and acetic acids. Or, when the reaction was checked for about six hours, acetate of potassium was found with that of copper. In the case of methy alcohol copper formate was produced, but afterwards decomposed, carbonic and formic acids being liberated; and from propyl alcohol a small quantity of what was probably one of the isomeric forms of lactic acid was formed. The precipitated cuprous oxide always occurred as very brilliant, reddish-violet, and octahedral cubes, and the metallic copper as microscopic crystals in the form of prisms terminated by quadrangular pyramids (Comp. rend., crix., 582).

M. Desmond finds the composition of the gaseous mixture given off by wood charcoal distilled at a dull red heat to be as follows:—carbon dioxide, 91 per cent.; oxygen, 0.26; carbon monoxide, 18.08; hydrogen, 49.11; marsh gas, 16.04; nitrogen, 7.37. After the operation the charcoal possesses its ordinary appearance, and burns freely without smoke or odour. The source of the gases, it is suggested, may possibly be a solid or liquid organic base condensed in the charcoal (Comp. rend., crix., 733).

R. Varet, continuing his work on Nitrates of Mercury. R. Varet, heat of formation of the nitrates of mercury, and finds that, as in the case of the sulphate (ante p. 353), the reaction by which neutral mercury nitrate, \( \text{Hg}_2\text{NO}_3 \cdot \text{H}_2\text{O} \), is decomposed by water is the least endothermic. He states also that nitric acid, like sulphuric, picric, acetic, and oxalic acids, when combined with oxide of mercury, is completely displaced by hydrochloric or hydroxyacetic acid (Comp. rend., crix., 797).
Thiosapce. A method of preparing sulphurated soap has been made the subject of a patent by Rudel, of Berlin. It consists in heating unsaturated fats or fat acids, such as olein or oleic acid, with sulphur to a temperature of 120° to 160°C. Sulphur then enters into combination, and when oleic acid is operated upon the product contains about 10 per cent. of sulphur.

\[ \text{C}_{18}\text{H}_{36}\text{O}_7 + \text{S} = \text{C}_{18}\text{H}_{35}\text{SO}_3\ ]

The sulphurated product dissolves in ether or turpentine without separation of sulphur, and when saponified by a molecular proportion of caustic alkali, the soap dissolves completely in water or alcohol. Soap containing sulphur in this state of combination has been found very serviceable in the treatment of skin diseases by Drs. Eshhoff and Hager (\textit{Apotheker Zeitung}, 1894, p. 665).

Scopoelone. The formation of acetyl derivatives of scopelone cannot be effected, according to Luboldt, by heating the salts of scopelone with hydrochloric acid, but by heating scopelone with salicyl alcohol, he succeeded in obtaining salicyl scopoeline, \(\text{C}_{18}\text{H}_{23}\text{NO}_4\). It is a colourless crystalline substance, soluble in alcohol or chloroform, melting at 105°C, and destitute of mydriatic action. Benzoyl-scopoeline was obtained by Hesse in 1892 by the action of benzoyl chloride upon scopoeline. E. Schmidt has prepared acetyl scopoeline by the reaction of scopoeline with acetyl chloride or acetic anhydride, as a readily soluble crystalline substance melting at 92°C. (\textit{Apotheker Zeitung}, 1894, p. 869).

As a non-poisonous antiseptic preparation that is soluble in water, Bennegeau recommends a mixture of two molecular proportions of sodium salicylate with four of boric acid. The finely powdered ingredients intimately mixed with additional water yield a hard mass which is dried and powdered. The reaction taking place is represented by the following equation:

\[ 2(\text{C}_9\text{H}_8\text{OHCOONa}) + \text{Na}_2\text{B}_4\text{O}_7 + 4\text{B}(\text{OH})_3 \rightarrow 2(\text{C}_9\text{H}_8\text{OHCOOH}) + 6\text{NaB}_4\text{O}_7 + 4\text{H}_2\text{O} \]

The temperature at which water possesses its maximum density has recently been re-determined by J. Cooper, who finds it to be 3°C to 3.9°C at the normal atmospheric pressure. In carrying out his experiments, he immersed a vessel of water containing a number of thermometers whose bulbs were arranged at different heights in an outer vessel of cold water. The convection currents set up as the water cooled commenced by passing down the sides of the vessel and up the middle, but after a while they ceased and then became reversed. As the heaviest water sinks to the bottom of the vessel, the temperature registered by the lowest thermometer was taken as that of maximum density (Ann. chim. phys. [7], iii., 246–268).

H. Moisson finds, as the result of extended experiments, that the vapour of carbon invariably condenses in the form of graphite.

The former compound amongst the graphite, which constituted the larger proportion of the deposits, like graphite, became tetrachloride, carbon specific gravity, and passes from the solid to the gaseous form without passing through the intermediate liquid state. It is not unlikely, however, that carbon may be liquefied, but this phenomenon will require the application of more or less pressure. Great pressure results in an augmentation of the density of the carbon, and the diamond can thus be produced, but the application of the right degree of pressure may bring the element to the liquid state, and the fluid may then solidify like water, either presenting a confused mass of crystaline of enameled, hard and opaque porcelain, or those diamonds occasionally found at the Cape or in Brazil, which possess no apparent trace of crystallisation (\textit{Comp. rend.}, cit., p. 776).

Salacetol. A preparation consisting of the sodium salts of salicylic and boric acids has been introduced under this name, and when dissolved in a 1 per cent. solution of hydroperoxide it is recommended as an efficient remedy for diphtheria. According to the results obtained in its use for that purpose by Dr. Wall, or other physicians, it is not to be very much more efficacious than the anti-diphtheritic substance of Behring. The solution is applied to the throat with a brush every four hours, and in the intervals its solution is used as a gargle. It is also stated to act as a prophylactic. Application has been made for a patent for the preparation of salacetol, and its manufacture is being carried out at the factory of Karl Fr. Toller in Bremen.

New Medicinal Agents. The following articles of recent interest are described in \textit{Pharm. Centralblatt}.

- 
  \textit{Antitoxine} is a solution of quinine which has been employed by Zambelotti in the treatment of influenza, rheumatic and neuralgic affections, etc., in doses of from 3 to 4 grains (12 to 23 grains in the twenty-four hours).
  \textit{Bismuth Sulphite}, used by Cessar and Raccher as an antiseptic in the treatment of fermentive orders of the stomach and intestines, and dislodging worms (Boll. chim. farm.).
  \textit{Calcium Borate}, used by Alberti in the treatment of suppurating inflammation of the eyes (Boll. chim. farm.).
  \textit{Chloroiodolopol}. - chlorinated derivative of phenol cresacate guiltiacol, used by Zambelotti as an inhalation for chronic affections of the respiratory organs.

\textbf{Extract of Hemp.}—This is a dietetic preparation introduced by T. Barthelson, of Hjerppe, in the case of consumptive patients, etc. According to an analysis by Dr. L. Spiegel it consists of:

- Sugar........................................................................... 515
- Albuminous substances............................................. 255
- Fat (hemp oil).............................................................. 80
- Ash............................................................................ 10
- Water.......................................................................... 105

The preparation is sold by H. Schutte and Berlin. 

\textbf{Salicyberrin}, or 
\textbf{Salycytaniolide}, is a white powder powder consisting of a mixture of acetate and salicylic acid, insoluble in water, but soluble in alcohol. 

\textbf{Salmiophenol} : colourless crystals, consisting of a mixture of meta- chloride and phenolate, prepared, according to Dessequeile, by mixing molecular proportions
The ascent of sap has eliminated the direct action of living protoplasm from the problem, and that the explanation thus remained to be sought in the turgor tissue and the transpiration activity of the leaf. The ascent would appear to be principally in the lumen and not in the wall, and the stable condition of the ascending sap probably accounts for the transmission of the tensile strain without rupture of the column of liquid. The transmission of this tensile stress to the root would result in the rapid condensation of water from the surrounding soil by the capillaries of the root-surface. The power possessed even by a root injured by lifting from the soil, of condensing water vapour from a damp atmosphere, was shown by experiment. A system, consisting of two porous pots connected by a tube, when filled with water enabled the authors to illustrate how the "leaf" exposed to the air gives off vapour, while the "root" buried in damp earth supplies the demands of the "leaf," and an upward current in the connecting tube is thus established as in the case of the living plants. (Nature, lii. 33.)

M. Roze has investigated the cause of the ejection of the seeds of Elaterium, the squirming cucumber. By cutting off, or making an opening in, the apex of the fruit at different stages of maturity, he found that the force exerted is in proportion to the ripeness of the fruits, for when the seeds were still white and immature they were expelled slowly and one by one. The pressure exerted appears to take place almost equally in a longitudinal and transverse direction, since whether the opening in the nearly mature fruit was made at the apex or on the side, the seeds were expelled in both cases. When the fruit from which the seeds had been ejected was cut open longitudinally a centrifugal action was indicated, the disintegrations, still swollen with liquid, becoming raised, while the walls of the fruit seemed to be depressed, but when the unripe fruits were cut in opposite or centrifugal action seemed to take place, the two halves of a fruit cut longitudinally closing rapidly until the surface of the cut diminished to nearly half its width, caused probably in part by the sudden release of the seeds; the halves then curved into the form of an arc. The author alludes to the changes that take place in the chlorophyll of the epidermis, but does not seem to have noticed the explanation of the cause of the ejection of the seeds given by Fluckiger and Hanbury in Pharmacographia. M. Roze has, however, demonstrated the curious fact that the pressure is not due to an access of fluid from the plant, since fruits not mature, with the peduncle attached, placed either in hermetically sealed, or loosely covered, flasks, ejected their seeds in periods varying from four to ten days (Journ. de Bot., viii., 308).

An illustration of this plant, which Willughbadea Firma. is stated to yield a good indiarubber in the Malay Peninsula and Archipelago, from Sumatra to Borneo, is given in the Icones Plantarum, Pl. 2344. It appears from the material at Kew that there are several varieties of the plant, but the form figured is considered by Dr. Stapf to be the typical one described by Blume.
Berthalot and André showed, some time ago, that the leaves of different plants gave off a certain proportion of carbon dioxide when heated between 100° and 110°, in a current of hydrogen. This liberation is independent of biological phenomena or of the presence of oxygen, and would seem to indicate the existence in leaves of compounds which are easily decomposed, giving off carbon dioxide. Substituting air or oxygen for hydrogen, double the quantity of carbon dioxide was liberated, this phenomenon demonstrating the presence of oxidizable compounds, also capable of yielding carbon dioxide. The relation between the oxygen absorbed and the carbon dioxide produced was investigated, and it was found that the amount of the former constantly exceeded that of the compound gas. It was thus apparent that the products of the oxidizable matter in the leaves can be accumulated under certain conditions, independently of the carbon dioxide exhaled, the absorption of the one gas and generation of the other not being directly connected, as in the case of the higher animals. Recent experiments on the purely chemical formation of carbon dioxide by the decomposition of certain proximate principles in leaves, have been performed chiefly with those of the ivy. They were dried at 110°, powdered, and heated in an atmosphere of hydrogen, on an oil bath maintained at 120° to 130°, with a 12 per cent. aqueous solution of hydrochloric acid, until the carbon dioxide was obtained. These conditions are similar to those under which furfuroil is produced, and the authors have now induced to initiate experiments in which definite proximate principles shall be treated singly, instead of continuing to work on leaves. In one such experiment cane sugar was operated upon under the same conditions as the leaves, and carbon dioxide was similarly disengaged, whilst furfuroil and certain acids were also formed. Other experiments, in which various carbohydrates are employed, are now proceeding, and, it is hoped, may throw some light upon the origin and composition of the compounds thus formed, as we begin to understand the nature of the chemical reactions occurring in connection with the respiration of plants (Comp. rend., cxix., 711).

In the Icones Plantarum for November, Pl. 2331, an illustration is given of the small-leaved Jaborandi plant which was named by Dr. Stapf Philodendron microphyllum. The leaves of the plant are imparipinnate, with about three pairs of leaflets, sometimes reduced to two pairs only, and the raceme is probably only one and a-half to two inches long. The flowers are described from the bud, and the fruit from a carpel picked out of the leaves sent to the Kew Museum as a new Jaborandi by Messrs. Evans, Sons and Co., of Liverpool.

Tabernanthe iboga, a remarkable plant used by the natives of the Gaboon and Congo is described and illustrated in the Icones Plantarum, Pl. 2337, under the name of Tabernanthe iboga, Baill. The root was first sent to Kew in 1866 by Dr. Hugo Mueller under the native Congo name of “Boca root” and was said to be much used, and valued on the Lower Congo as a februge. Professor Baillon says that it is known at Cape Lopes as “Iboga,” and that it is the “Aboua” of the Pahoins, and the “Obouata” of the Gaboes. The latter people are said to consider it to be toxicating, aphrodisiac, and to prevent a tendency to sleep. From a botanical point of view it differs from the genus Tabernanthe chiefly in the solidification of the carpels.

Platinum Calletet and Collardeau, in a paper on the condensation by porous bodies of hydrogen produced during the electrolysis of water, give the results of experiments with a solution of spongy platinum and palladium, or of a divided gold, iridium, or ruthenium, contained in the electrolytic gases, and produce a gas better which, on subsequent connection of the polar capable of giving up the stored energy. The metals of the platinum family alone seem to be accumulators of condensed gas, of which the capacity increases with the pressure. With silver, copper, nickel, cobalt, and carbon, this is not so, but in the case of platinum and iridium the storage capacity attained may greatly exceed that of the lead accumulators. In connection with this subject M. Berthalot referred, at the meeting when paper was read, to the fact that platinum and palladium, and analogous metals form in definite combinations with free hydrogen and oxygen. Thus platinum forms two hydrates of which is stable at 200° whilst the other is associated by cold. It is to these compounds properties are due which were formerly ascribed to the occlusion of gases. Two platinum electropositive charged with hydrogen and oxygen respectively, and accumulated with an iron core would work an electric current, and this fact explains formation of the new accumulators (Comp. cxxxix., 830).

A. Dastre still maintains the so-called “saline digestion” without Ferments, Pharm. Journ. [3], xxiv., 106 (1087) is due neither to soluble elements nor to microbes. With regard to former, he contends that the digestive ferments cannot possibly act in such strongly concentrated saline solutions as he employed in his experiments, albuminoid matter under such circumstances remaining unaffected by them. As to organisms, no trace of such could be detected in the medium in which the saline digestion was taking place. Finally, the detailed results published of some additional experiments, which the presence of soluble ferments or microbes was carefully avoided, and digested proceeded apparently by the action of salines alone (Comp. rend., cxxxix, 837).

Circulation of the Blood. Wharton mentioned an interesting experiment by which Mosso shows that blood flows in increased amount to the greatest activity in the body. When a man upon a carefully balanced board commenced to think, the increased flow of blood to the head was observed. The increased flow of blood to the board downward at that end. An interesting note in Rees' Encyclopaedia indicates that some knowledge of this circulatory change was possessed by anatomists long before that of Harvey, to whom the discovery is attributed. The fact that the blood circulated...
through the lungs was clearly stated by Servetus in his 'Rerstitutio Christianiarni,' a work which he published anonymously, but of which Calvin proved him to be author. For writing this work Servetus was burned in the forty-fourth year of his age, in 1553, with the approval of both Calvin and Melancthon. The fate of this work has been not a little singular, all the copies having been burned along with the author by the implacable Calvin, save one secreted and saved by Dr. Colladon, one of the judges. After passing through the library of the Landgrave of Hesse Cassel, this copy came into the hands of Dr. Mead, who endeavoured to give a quarto edition of it, but before it was nearly completed it was secured by John Kent, messenger of the press, and William Squire, messenger in ordinary, on May 27, 1723, at the instance of Dr. Gibson, Bishop of London, and Hume, a few copies excepted. Although Harvey's work was less severely treated, he met with the utmost opposition from the faculty, and even from those who were not interested in maintaining the 16th order of things, and he complained to a friend that his practice had considerably declined since his publication of his discovery.

**Atmospheric Variations in the Higher Atmosphere.**

The presidential address of Mr. Richard Inwards to the Meteorological Society contained an account of some observations by M. Hermit on the temperatures and pressures at various heights in the atmosphere. The experiments were conducted by means of captive balloons carrying such necessary instruments. One of the balloons rose to a height of ten miles, and registered a pressure of only 41 inches of mercury, and a temperature of 104° below zero! It was found that the temperature does not fall regularly during the first twelve thousand feet above sea level, but falls is believed to be fairly regular at greater heights, and amounts to about 1° F. for each 390 feet of rise.

**Meteors and the Meteorite Iron.**

The meteoric iron and the meteor containing iron, which reach the earth, are usually coated with a black crust produced by the intense heat generated by their passage through the atmosphere, the body of the stone, when not metallic, being greenish. M. Enriques, however, describes the Cometa renda meteor whose surface was entirely white, the interior being almost black. The crust consisted of leucite sulphide, probably produced by the action of heat, as a similar coating was formed when a portion of the black substance was heated in the hottest part of a blow-pipe flame. In connection with this object it is interesting to remember that in 1891 r. Foote discovered diamonds in a meteorite and in the Catoro Diablo, Arizona, a discovery of interest in relation to the opinion that the diamond of igneous origin.

**Densities and Specific Gravity.**

Kohlausch and Hallwachs describe in Wiedemann's Annalen a method of determining the specific gravity of very dilute aqueous solutions with greater nicety than has hitherto been attained. It consists in weighing a glass beaker suspended in the liquid by a single cocoon fibre. From the weight of the globe in pure water, and also in the solution to be tested, the specific gravity is calculated as usual. The liquid being tested is mixed with a glass rod bent into a horizontal ring and carrying a ring of platinum foil. During the stirring operation the globe is supported by another ring. The thermometer used for ascertaining the temperature may be read to a thousandth of a degree by means of a telescope, but the balance used for weighing need not be of excessive delicacy. Although the globe weighed nearly 2000 grains in air, it was of such a size that it weighed less than 60 grains when suspended in water, so that the maximum weight which the silken thread was required to support never exceeded 60 grams in the experiments carried out by these observers. Their observations are said to have given indications to about the millionth part of the density determined.

**The Discovery of Oxygen.**

**Introduction.**

At a time like the present, when chemistry is advancing by leaps and bounds, and being enriched by fresh discoveries, almost daily occurrence, it is difficult to realize that its claim to be regarded as an exact science is practically based on the results of investigations undertaken within little more than the last hundred years. But, in truth, it was not until Lavoisier rounded off his own researches by interpreting the phenomena disclosed by the labours of Black, Cavendish, Priestley, and Scheele, that any such claim was at all justified. Chief among the mass of material collected by his illustrious predecessors and co-workers were the facts ascertained by Priestley, in England, and Scheele, in Sweden, regarding oxygen gas, which they discovered independently of each other and almost simultaneously. This discovery afforded Lavoisier one of his most potent weapons in waging war upon the phlogiston theory, and served as the basis of the new system which inaugurated the modern era of chemistry.

But long before the actual discovery of oxygen, the idea was prevalent among chemists that, in some way, there was a connection between the air we respire and the process of combustion. It was observed that fire cannot exist without air, but that nitre produced the same effect as a blast of air, i.e., it caused greatly augmented combustion. Metals also were calcined by the aid of nitre or its spirit (nitric acid) as well as in a current of air. Accordingly, it was common to speak of the presence of nitre in the air, and Robert Hooke, in his "Micrographia," published in 1665, asserted that it was the constituent of air fixed in saltpetre which effected combustion. Hooke's experiments were continued by John Mayow, who identified the "dissolving part" of air and of saltpetre under the name of nitre-air or fire-air, and regarded it as an essential constituent of all acids. He also assumed it to be the cause of fermentation and putrefaction, and proved that it is essential to respiration, which he showed to be analogous to combustion. He further demonstrated the mixed nature of air, recognizing in it a supporter of life and combustion, heavier than the air itself, and a body lighter than air, incapable of supporting life or combustion.
THE PHLOGiston THEORY.

About this period, however, Beecroft and Stahl's theory of phlogiston was propounded, and soon gained general acceptance, the work of Hooke and Mayow being apparently quite lost sight of for the time. That theory explained the phenomena of combustion and other analogous processes by the assumption of the hypothetical phlogiston, "the most pure and simple inflammable principle" — not actual fire but the principle of fire. Phlogiston was originally understood to be a very subtle, invisible substance, capable of penetrating the densest matter and conferring negative weight. Later, it was identified with hydrogen, but the theory had been, by that time, discarded as a working hypothesis by most chemists. All combustible bodies were supposed to be very rich in phlogiston, which they lost when burned; on the other hand, the assimilation of phlogiston by unflammable substances resulted in the formation of inflammable compounds. The rusting of iron, the calcination of lead, and the production of sulphuric acid by burning sulphur, were attributed to phlogiston; and the reduction of metallic compounds to the assimilation of this imponderable principle. In other words, what we now term oxidation was regarded as loss of phlogiston, and de-oxygenation as the reverse.

The work of both Priestley and Scheele, as will be seen later, was vitiated by their belief in the phlogiston theory, which influenced chemistry for a whole century and hindered their full comprehension of the phenomena observed during their labours. It was reserved for Lavoisier to carry the results obtained to their logical conclusion and so explode the hypothesis which had now become more than ever a check upon the progress of the science. The observations of Priestley and Scheele with respect to oxygen (so named by Lavoisier, from $\psi$, acid, and $\gamma\rho\phi\alpha\iota\sigma\iota\varsigma$, to produce) enabled him to establish his theory of combustion or oxidation, according to which, substances burn only in oxygen and increase in weight proportionately to the amount of oxygen consumed in the process. Cavendish had already shown that water alone is produced by the combustion of hydrogen, and Lavoisier was thus able to state the real composition of water. He also correctly interpreted the decomposition of water by red-hot iron, its formation when metallic oxides were reduced by means of hydrogen, and the generation of hydrogen when metals were dissolved by acids, since he saw that the hydrogen came from the water and that the oxygen from which it was liberated united with the metal to form oxide, which in turn combined with the acid to form a salt. The outcome of these and other experiments was the general recognition of the non-existence of phlogiston and the confirmation of Hooke and Mayow's opinion that one only of the two normal gaseous constituents of atmospheric air is essential to combustion, calcination, and respiration. Lavoisier was thus enabled to translate into simple antiphlogistic language, the obscure and erroneous reactions in which phlogiston was assumed, and, by the joint labours of Priestley, Scheele, and himself, to raise upon the ruins of the phlogiston theory the structure of modern chemistry. The manner in which the great discovery was made by the two investigators, Priestley and Scheele, whose results agreed though their methods differed, must now be described, and with a view to showing the difficulties under which they worked, the accounts will be couched as far as seems advisable in the language of the originals.

Revision of the Pharmacopoeia.*

"In reference to the important subject of the British Pharmacopoeia, I would recall the attention of the Council to the subject by a reference which I made to it in the address which I had the privilege of delivering in November, 1899: —

"Another matter of importance which I have to report has relation to the Pharmacopoeia. The Council will remember that during the Session of May, 1892, a communication had been received from the Secretary of State for India on the subject of reports forwarded from the medical authorities in that country, pointing out certain inconveniences which resulted from their belief that the British Pharmacopoeia, to use certain drugs which could be substituted by others of an equivalent value, indigenous to India, without incurring the expense of importation. Other matters of importance and interest were likewise indicated.

"At the meeting of the Council in May, 1893, the Pharmacopoeia Committee was authorised to enter into correspondence, through the Privy Council, with the India Office and the Colonial Office, with a view of ascertaining in what degree, if any, the British Pharmacopoeia could be better fitted than at present to meet Indian and colonial requirements as regards important natural drugs and pharmaceutical preparations.

"The replies to the communication thus authorised (twenty-eight in number) have been very satisfactory. They have been received from the East and West Indies, and from the colonies and dependencies in South Africa and Australia. A full statement concerning these communications will be submitted to the Pharmacopoeia Committee by Professor Atfield, and subsequently they will be laid before the Council by the Committee.

"I need scarcely remind you of that with which we are all familiar, viz., the discussion which is taking place as to the relations between the mother country and the colonies, and between the various colonies themselves.

"It will therefore be regarded as a fortunate coincidence that at this moment the Council should have determined that the members of the medical profession in this country and those members of the profession practising in those remote regions in which British thoughts, British feelings, and British wants predominate, should become more closely bound together, and that the Council should be prepared to utilise the valuable suggestions which they have received from these dependencies, and thus to render

* Extract from the address of the President of the General Medical Council, Sir Richard Quain, Bart., at the opening of the fifty-seventh session.
the Pharmacopoeia not merely English, but British in the widest sense of the term.

"And here I feel it my pleasing duty to acknowledge the readiness with which the Privy Council Office, through Sir Charles Peel, undertook to communicate with the India and the Colonial Offices, and also to notice the very excellent results which have accrued from these communications. We have to express our acknowledgments to these several departments for obtaining for us the necessary returns, which have been very readily and abundantly supplied by the medical authorities in India and the colonies."

THE PROPOSED 'IMPERIAL' PHARMACOPEIA.

The publication of the following expressions of opinion by several representative British pharmacists, in reference to this aspect of pharmacopoeia revision, seems particularly appropriate in the present number of the Journal, and, it is hoped, may lead to the formation of some general consensus of opinion on a subject of primary importance to pharmacists throughout the British Empire:

"It may be assumed that the British Pharmacopoeia is already the principal guide or authority used in the colonies by medical practitioners and pharmacists in the prescribing and dispensing of medicines, although some other pharmacopoeias may be occasionally required, as in this country. The British Pharmacopoeia is, therefore, in the voluntary sense, the Pharmacopoeia of the entire British Empire. The more the work be brought up to date as a 'British Pharmacopoeia,' the more it may be expected to command the respect of the colonies. This is particularly noticeable in the recommendations which have been received from Victoria, Australia. Many of the suggestions might well have emanated from a committee resident in Great Britain, and reporting upon the British Pharmacopoeia. The difficulty commences when the purely colonial side of the subject is considered, namely, the extent to which species and localities, which would not otherwise be recognised in a 'British Pharmacopoeia,' should be included in an 'Imperial Pharmacopoeia,' which nevertheless has to be the official guide for this country.

"It is well known that, even in a small area such as Great Britain, certain drugs and medicinal preparations are in favour in some localities, but quite neglected in others, and this is likely to obtain to a much greater extent when the area is increased so as to include the globe.

"It has been stated that theories of this kind must depend upon the supposition that the indigenous remedies are specially useful for ailments which are peculiar to particular countries; but that argument would apply equally well to the continent of Europe alone, and yet a 'European Pharmacopoeia' would be almost an impossibility.

"It appears, therefore, that the question how far an 'Imperial Pharmacopoeia' (from the point of view of a compulsory authority for all the colonies) is desirable or feasible, can only be settled by the colonies themselves. If they will be satisfied to be ruled by an improved British Pharmacopoeia, then, as a matter of course, it would become an 'Imperial Pharmacopoeia'; if, on the other hand, they would desire a complete revolution of the lines upon which the British Pharmacopoeia exists, then British pharmacy might lose more than colonial pharmacy would gain. An obvious alternative is to have appendices for such colonies."

"That the national Pharmacopoeia should suffice for the needs of all the British Colonies and possessions was an idea actuated the General Medical Council in its production, for in the preface to the 1867 issue it is distinctly said to be 'intended to afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide, whereby the nature and composition of substances to be used in medicine may be ascertained and determined.' While the term 'Imperial British Pharmacopoeia' is suggestive of a palpable contradiction in terms, it is difficult to conceive what further meaning can be conveyed by the term 'Imperial Pharmacopoeia.' There is, therefore, no novelty in the adaptation of the Pharmacopoeia to colonial needs, and the only question to be considered is how that object may be secured most effectually.

"With regard to the extent of the modifications allowable on this ground, there is clearly no occasion for flooding the Pharmacopoeia with colonial-grown drugs, concerning the medicinal value of which little or nothing is yet definitely known. When, for example, Australian rhubarb, opium, essential oils, etc., shall have been proved equal in medicinal virtue to those now official, it will be soon enough to put them on an equal footing. If such drugs are now considered satisfactory by the medical practitioners of the colony, it may be desirable that the use of them should be sanctioned for that colony, without interfering with the established practice of British pharmacists.

"The chief direction in which simplicity can be attained is in modifying existing formulae, and omitting a number of substances which have practically gone out of use, but have hitherto been retained through sentimental considerations. The directions for preparing substances of definite chemical composition could very well be omitted in all cases. Among galenical preparations many of the processes for making extracts in the present edition are obsolete, and are perhaps rarely followed in their entirety by persons engaged in their manufacture. Re-percolation might be utilised for some, with the object of reducing the volume of liquor to be evaporated, and in the case of the liquid extracts—egot, for instance—a judicious application of that process would obviate the necessity of evaporating any but the last and weakest percolate. Speaking generally, in many of the present processes too much menstruum is employed, leading to a waste of time and material, in addition to the deterioration generally resulting from prolonged application of heat to vegetable products.

"The tincture processes need revision as to the alcoholic strength of the menstruum employed, for the elucidation of which a good deal of work has been alread
done. A more intelligent application of the principles of percolation is also required, since the advantages of the process are only partially secured by the directions now given for making the percolated tinctures. The juices, if retained, should be standardized, or at least those of belladonna, hemlock, and henbane. The possibility of utilizing chloroform as a preservative in place of the more expensive alcohol, in some cases where the solvent action of the latter is not required, is also worthy of consideration.

"The formulae for enemas might be omitted; probably the present official enemas are little used, these preparations being usually made extemporaneously as required. The same applies also to the poultice. Let anyone who has prepared a linseed or mustard poultice consider how far the official directions have been followed. The formulae for suppositories are also unnecessary. Even in the case of the substances from which the official suppositories are made, other strengths than those ordered are required. It might perhaps be advisable to indicate officially the weight and the basis to be employed, unless otherwise ordered, and then all the present formulae could be omitted; the prescriber ordering what he wished and the amounts for each suppository.

"Speaking generally, it would seem advisable to make official only such simple galenicals as are required for exhibiting the active properties of the various drugs and leave the combination of these in the form of mixture, pill, suppository, etc., to the prescriber. In certain cases where a prolonged or complicated process is necessary to secure the desired result, e.g., ung. hydragr., special formulae may be advisable, but all simple mixing of substances, as in many of the ointments, where again strengths other than those official are frequently employed, might well be omitted. Otherwise, to be logical, formulae for mixtures, pills, ointments, etc., should be made official for all drugs commonly used in these forms—a proceeding which would undoubtedly lead to the further extension of factory-made phials. The reduction in the number of such unnecessary formulae would obviously reduce the points at issue between medical practice in the various colonies and the mother country, thus facilitating the removal of any possible obstacles to the recognition of the British Pharmacopoeia as the authoritative standard for the whole empire."

"It is quite reasonable to assume that the time has arrived when the Pharmacopoeia should be constructed on a broader basis, including the drugs and formulae now used almost exclusively in our colonies, and thus constituting an 'Imperial Pharmacopoeia.' This brings it new editorial responsibilities, and is a subject for serious consideration amongst British pharmacists. It is usually expected by medical men that the dispensing chemist will have in stock all the drugs and preparations contained in the Pharmacopoeia, and if there is to be a large addition, it means, possibly, an increase of stock for which there will be but little demand. But this evil is not so great as would at first appear, and when the matter is gone into it may be found that the necessary additions are not so very numerous. We owe something to our colonies for valuable remedies already introduced into this country, and any increase in this direction should be welcomed and recognised by rendering such remedies official. It may be expected, too, that an Imperial Pharmacopoeia would come into more general use amongst our colonial brethren than the British Pharmacopoeia now does. From a commercial point of view there would be material advantages, as no doubt an increase in the import of drugs and export of preparations would follow. We should thus be using to the best advantage the means at our disposal for the mutual advantage of all concerned."

"It must be borne in mind that our Pharmacopoeia is primarily a British Pharmacopoeia. Therefore our conception as to what should appear in it need not, on the one hand, embrace everything that may be employed in each colony of the empire, nor, on the other hand, must it be limited to the drugs in vogue in any one part of the British Isles. And, just as conditions of space affect it, so also must time. It must be remembered that 'possession is nine-tenths of the law,' and that therefore it would take very much stronger evidence in favour of the admission of a new drug into the Pharmacopoeia than would be necessary to secure the retention of one which is already official. One would almost require to have a sort of guarantee or 'suspence' list into which new drugs might be put in order that their vitality and expectation of life might be certified before passing them on to the Pharmacopoeia. It would, indeed, require a cool head to steer through the contradictory suggestions as to deletions or additions which have appeared in this Journal from pharmacists at home, or from our Victorian friends. Still, these suggestions have their value, and all analytical and statistical investigations into prescriptions cannot fail to be of service when the question of selection comes to be decided. If the Pharmacopoeia, on the other hand, is to command respect beyond the seas, it is equally plain that the drugs and preparations included must not only fairly represent medical practice in these countries, but must admit of a wide variation to suit the altered climatic conditions. 'It is a far cry to Loch Awe,' but it is a still further cry from the winter of Canada to the summer of India. Our syrups, ointments, and other preparations, should therefore be prepared to accommodate themselves to such differences. These and other considerations point to the necessity of producing, first, a British Pharmacopoeia, extended, complete, and up to date on all points, and, after that, adding appendices to satisfy the needs or wishes of our colonies. In these appendices, not only would native plants be recognised, additional drugs and preparations be included, but variations from the British standard in the composition of ointments, syrups, and the like, would be legalised, either specifically or in general terms. In this way alone can we hope to make the Pharmacopoeia the standard work and legal referee throughout the empire, without doing injustice to the natural products of the colonies."
"Invitations to the colonies for suggestions respecting the inclusion in the Pharmacopoeia of drugs peculiar to the country and already in use there are being responded to; but if one is to judge from the reply from Australia these wants will be satisfied without much difficulty. When the replies are more complete, it will perhaps be found that the demand for an Imperial Pharmacopoeia is less pressing than appeared at first sight. In fact, to many who have had practical experience in the colonies, it is astonishing to find how little the professional aspect of pharmacy differs from the conditions that obtain in Great Britain. Probably most, if not all, the medicinal plants indigenous to the various British colonies find their way into the London markets, and, in cases where their value has been well proven, even into the Pharmacopoeia itself. This being so, it becomes a moot point whether the Pharmacopoeia brought thoroughly up to date will not be 'Imperial' in the widest sense. Any difficulty that might arise could be met by foot-notes under the various headings, authorising the substitution in the colonies of certain native products for those officially presented for use in Great Britain. For instance, under the title 'Oleum Oliva,' permission might be given to substitute 'Nut Oil' or 'Sesame Oil.' Should such latitude not be found sufficient to meet colonial requirements, it would then be necessary to consider whether it would not be more advantageous to issue a series of appendices instead of altering the character of the existing work. Although the question of an 'Imperial Pharmacopoeia' is receiving the lion's share of attention, it is doubtful if it involves such weighty considerations as the replacement of the present weights and measures by the adoption of the metric system would do. Another point that will claim the careful attention of the revisors, is the standardising of the more potent preparations in the Pharmacopoeia. Although much valuable work has been done in connection with that subject, it is doubtful if our methods are sufficiently reliable for incorporation into the standard work, since pharmacopoeial requirements and assay processes are liable to be made the basis of legal prosecution by public analysts."

LATEX-HAIRS OF THE CICHIORACER.

Herr L. Kny has investigated the cause of the excretion of latex which takes place when the scales of the involucres of various species of Lactuca, Sonchus, Malvidium, Prenanthes, Picris, and Lapsana are subjected to slight pressure. The example specially studied was Lactuca scorrida. The laticiferous system follows, in general terms, the course of the vascular bundles; but its ultimate branches became detached from the latter, and, in places, pierce the epidermis in the form of narrow cylindrical hairs filled with latex. They are found almost exclusively on those portions of the bracts which are not covered by other bracts; each of the outermost whorl of bracts may have not less than from six to one hundred. They are readily distinguished by their form, and by their very thin wall, as well as by their contents, from the ordinary papillae of the epidermis (Sitzber. Gesell. Naturf. Freunde, Berlin, 1893.)

Pharmacy at Home and Abroad.

The following information has been compiled so as to enable comparison to be made between the conditions of pharmacy here and elsewhere, the particulars concerning Great Britain being intended chiefly for the benefit of readers abroad, but also, in a lesser degree, for those British pharmacists who do not appear to have thoroughly grasped the bearing of the Pharmacy Acts, 1855 and 1868, upon their business, or realised the limitations of the powers possessed by the Pharmaceutical Society of Great Britain.

It cannot be too plainly recognised that proper training and qualification of pharmacists in this country is enforced by the State, simply as the best means of ensuring the safety of the public in respect to the sale and dispensing of poisons. State protection of the general business of pharmacy is not afforded, being but partially secured by passing the qualifying examination. Further, it is doubtful whether the legal powers conferred by the Acts upon the Pharmaceutical Society could be fully exercised unless the Society comprised the whole, or practically the whole, of the registered chemists in the country. In that case protection would be possible from within. By increasing the stringency of the entrance examination, insisting upon a real apprenticeship with a thorough course of technical training, and by maintaining the standard of qualification at the highest rather than at the lowest level, much might be effected. Still greater results would be obtained if the Society were a 'Federation' of the whole trade, if pharmacists in business refused to receive pupils who had not passed the scholastic examination, and if all registered persons steadily refused to play into the hands of unqualified opponents by affording them legal protection for the sake of a temporary advantage.

In many instances the time has not sufficed to procure exact information regarding the conditions under which pharmacy is practised in places abroad, and in others the information received is not so full as could be desired. It is requested, therefore, that anyone who can supply what is lacking, or amend what is now published, will kindly communicate with the Editor. To those who have already supplied information, much too numerous a body to be communicated with individually, the fullest thanks are hereby tendered.

GREAT BRITAIN.

The practice of pharmacy is less protected in this country than anywhere else in Europe, being, with certain limitations, free to everyone, without proof of training or qualification. The only protection accorded to registered persons is in respect of the titles—chemist and druggist, chemist, druggist, dispensing chemist or druggist, pharmacist, pharmaceutist, pharmaceutical chemist—and the sale or dispensing of such poisons as are scheduled under the Pharmacy Act of 1868. Even this protection partially fails as regards limited liability companies and other corporations, which, not being "persons" under the Act, are able to encroach upon the province of the pharmacist to the fullest extent, without let or hindrance, so long
as the business of a company is actually conducted by registered persons.

Registration has been enforced since 1868, and is granted after the candidate has passed an approved scholastic examination in Latin, English, and arithmetic; shown proof of three years’ training in dispensing; and, after attaining the full age of twenty-one years, passed a further examination—the “Minor”—in prescription reading, practical dispensing, pharmacy, materia medica, botany, chemistry and physics, practical chemistry, and the law relating to the sale of poisons. This examination occupies two days: it satisfies all legal requirements, and successful candidates are entitled to call themselves “chemists and druggists.” The title of pharmacist, pharmacist, or pharmaceutical chemist can only be assumed by chemists and druggists who have proceeded to a higher examination, the “Major,” which is purely voluntary. The subjects of examination are botany, materia medica, chemistry, and physics, all of a more advanced character than in the “Minor,” and embodying more practical work. The “Major” extends over three days, and successful candidates secure an extra privilege in being exempt from jury service. Pharmaceutical chemists are eligible as “Members” of the Pharmaceutical Society of Great Britain, and chemists and druggists are now eligible for election as “Associates,” whilst it is proposed to extend the privilege of membership to all duly registered persons.

The Society was established as a purely voluntary body in 1841, and incorporated by Royal Charter in 1843, after which all persons desiring to become members of the Society were required to be examined as to their fitness to carry on the business of pharmacy. In 1862 the first Pharmacy Act was passed, restricting the title of “pharmaceutical chemist” to persons who were already members of the Pharmaceutical Society, or should afterwards show proof of their skill and knowledge on examination. A register of pharmaceutical chemists was prepared in accordance with this Act. Later, the Act of 1868 was passed in response to public demand for a Poisons Bill, and a Poisons Schedule in which more and less potent agents are placed in separate classes, was then established. It was recognised by the Legislature that in the proper education of vendors of poisons lay the best assurance of the safety of the public, and accordingly the regulation of the practice of pharmacy for the purposes of the Act was entrusted to the Pharmaceutical Society, which had proved its fitness to be entrusted with that responsibility. Nothing in the Act extends to the business of medical practitioners, the making or dealing in patent medicines, nor to the supply of poisons by wholesale, so long as the regulations with respect to the labelling, etc., of poisons are observed.

As will have been gathered from what has been already stated, the 1868 Act is an imperfect one, in that it not only fails to restrict the practice of pharmacy to a properly educated class, but also only partially protects those who are legally qualified in accordance with its provisions. Even the Poisons Schedule is undesirably limited, and repeated attempts to extend it have been defeated by the action of the Privy Council, which controls the action of the Society in this respect. Again, though the educational standard of chemists and druggists has been steadily raised by the increasing stringency of the qualifying examination, the efforts of the Society in this respect have been in great measure neutralised by the lack of legal powers to insist upon candidates producing evidence of having undergone a proper course of scientific and technical training.

Seeing then that, as might be expected in a country where a minimum of State interference is tolerated by the people, the progress of pharmacy in Great Britain has been virtually by the slow and uncertain path of natural evolution, it is not to be wondered at that the art discloses itself under the most diverse aspects. Instances are readily found to illustrate every step in the process of development, from the miscellaneous dealer in drugs, grocery, drapery, ironmongery, etc., etc., to the high-class pharmacist who confines himself to pharmacy pure and simple, whilst at times acting as an expert in chemistry, bacteriology, and general hygiene. The future is very uncertain, but the educated pharmacist has, within the brief course of half a century, proved his ability to fill a gap in the social economy, and his chief need would now seem to be the recognition of the fact that—in a community where all institutions are, and are likely to be, undergoing change—he must be constantly prepared to adapt himself to modifications in his environment.

IRELAND.

In the sister island, which possesses its own pharmacy laws, pharmaceutical chemists enjoy an extra privilege as compared with their English and Scotch brethren, in that they possess the exclusive right to compound medical prescriptions.

Candidates for the qualification of pharmaceutical chemist are required to pass a preliminary examination in Latin, English, arithmetic, algebra, and geometry, as well as one of the following optional subjects:—elementary physics and mechanics; the rudiments of botany; elementary chemistry; French, German, or other modern language. This examination, it is evident, is a much better test of scholastic education than the corresponding British one, and, unlike the latter, it must be passed at least twelve months previous to entry for the licence examination. Candidates for this must be twenty-one years old and have acted as apprentice or assistant for four years or more, besides attending a three months’ course in practical chemistry. The subjects of examination are botany, materia medica, general and pharmaceutical chemistry (including physics), and practical pharmacy (including prescription reading and knowledge of the law relating to the sale of poisons). It is practically equivalent to the “Minor” examination under the British Act. Chemists and druggists under the Irish Act are entitled to keep open shop for the sale, retailing, or mixing of poisons, but not to compound medical prescriptions. The first must have been in business as principals before 1890, and are examined in reading, writing, arithmetic, and the appearances of the poisons, drugs, and chemical salts in common use. Registered druggists must have served as apprentice or assistant for four years, and are examined in English orthography
and composition, arithmetic, the weights and measures of the British Pharmacopoeia, and the appearance and properties of the various drugs and chemicals in common use.

**CANADA.**

The regulation of the practice of pharmacy in Canada is vested in the various provinces which compose the Dominion, each of them being competent to legislate for the purpose. As a matter of fact they have nearly all taken advantage of the privilege, as pharmacy laws exist in Ontario, Quebec, Nova Scotia, Manitoba, New Brunswick, British Columbia, and the North West Territories, this being also the order of sequence. The various Acts are more or less modelled after that of Ontario, which was passed in 1871, and, in turn, was based on the Act of 1868 of Great Britain. In all cases the regulation of pharmacy is controlled by provincial associations, or societies, which are generally so styled, but, in the case of Ontario, the body corporate is called a "college of pharmacy." The members of these societies were originally resident druggists, or qualified assistants, who were so engaged when the laws were enacted, but, since then, admission has been by examination, or the recognition of qualifications elsewhere obtained. The affairs of these societies are governed by councils elected and constituted similarly to that of Great Britain. The annual fees payable by the members of the various organizations range from four to ten dollars, and those in default are considered legally unqualified as druggists.

The laws as to the registration of assistants and apprentices are not the same. In Quebec and Manitoba all apprentices and clerks are required to pass specified examinations, register, and pay annual fees; and are then said to be "certified." In British Columbia there is a grade of "certified apprentices," but, in the other provinces, the statutes do not demand a registration of either assistants or apprentices. In Ontario, a register of apprentices is kept, and a fee of one dollar exacted by the so-called college. The sale of poisons is carried out in Ontario, Nova Scotia, Manitoba, British Columbia, and the North West Territories, in a manner similar to that specified by the British Act, the poison schedules being similar, and also divided into two parts, but, in Quebec and New Brunswick, this division is not made, and the full regulations, which in other places are only applicable to the first part, are in these provinces enforced in regard to the whole list.

The right of physicians to practice pharmacy appears to be discouraged in Ontario, as the amended Act contains a special provision for the registration of doctors as druggists. In Nova Scotia, Manitoba, British Columbia, and the North West Territories, they are not interfered with. In New Brunswick they need not pass an examination, but must register as druggists, and this regulation also obtains in the Province of Quebec, except in the cities of Quebec and Montreal, where physicians opening drug stores must cease to practice their former profession, and must not lend their names to businesses of which they are not the owners. Since the amendment of the Pharmacy Act in Ontario, this mode of evading the law has become exceedingly common, and was the principal subject of discussion at the last meeting of the council of that province.

The administration of the law is vested in the various pharmaceutical bodies, but they do not in general show much activity in carrying it out. In Quebec there have, of late, been several important prosecutions with varying results, but elsewhere the condition is one of legal apathy. The vexed question of the responsibility of the seller has not been prominently brought forward as in England, but as the laws in Canada are generally similar to our own, it is probable that the development of this feature is only a question of time.

Competition in prices has during the last year or so set in in some of the larger cities where bazaar stores exist. In some of these omnivorous establishments proprietary medicines, soaps, toilet articles, and such like, are sold at figures which would not allow a profit to small dealers, and it is accepted as a sign of the times that druggists' prices will never again be realised. A feeble attempt was made in Toronto to prosecute a large "dry goods" house—formerly doing business as drapers—but latterly adding almost everything else, including drugs—for selling a proprietary compound of which poison was a constituent. The case was not so successfully treated as has been the rule here, and, though a fine was inflicted, it was only nominal, and the house continued to do business as before. An attempt was then made to obtain amendments to the Ontario Act, by which the sale of proprietary medicines containing poison was to be restricted to druggists, but not only did the Legislature ignominiously dismiss the Bill, but passed another, by which all interference with such medicines is prevented. Class legislation has become very unpopular, and it is thought by those who should know that any further tampering with the commerce of pharmacy will result in the loss of most of those privileges which druggists have fought so hard to acquire.

The only hope of druggists seems to be in dispensing, but, unfortunately, in all but the larger cities and towns, the doctor puts up his own medicine, or if he sends a prescription to a druggist he expects a large percentage of the receipts. The granting of this commission is a very general thing, and we are led to understand that competition is so close between druggists that the initiative is not always taken by the doctor.

The recognition of qualifications other than those obtained by examination in the several provinces is in general left to the discretion of the respective councils or boards of examiners. In Quebec the Act specifies the certificate of pharmaceutical Boards whose educational requirements equal their own. In Ontario the Act mentions the "diploma" of the Pharmaceutical Society of Great Britain, and in British Columbia a similar "diploma from some reputable college of pharmacy" duly authorised by the laws of Great Britain is recognised. In New Brunswick "the diploma of any other competent body" is mentioned, and, in Manitoba, the certificate or diploma of some legally
qualified college or association may be accepted, while in the North West Territories such associations must be in Her Majesty's dominion. In most cases these qualifications must be submitted to the approval of the governing body, so that the power of rejection is thus really placed in their hands. It is likely that should a specified qualification not be recognised, the council or board might be required to show cause for such action. The Ontario college has already refused to recognise the qualification of any organisation which will not reciprocate, and the Pharmaceutical Society of Great Britain is one of these, as is also the Quebec Association.

A step in advance of this has lately been taken by the Ontario council, which has exercised its alleged discretionary power in discriminating between individuals holding a recognised reciprocal qualification. An American gentleman, who is now "dean" of the Ontario teaching college, was registered as a chemist and druggist, on the strength of a certificate of the Board of Pharmacy of the City of New York, while a young Canadian druggist, formerly a student of the Ontario college, who possessed the same qualification was refused registration, and has recently been prosecuted for keeping open shop. Further litigation is reported probable.

Manitoba has also taken a stand against general recognition, and it may be said that there is a strong feeling throughout the Dominion against accepting any qualification except that by examination of the governing body itself. Persons intending to go to Canada should in all cases submit their qualifications and have them decided upon before taking any final step.

Trade does not appear to be very good in Canada, as it shares in the general depression prevalent everywhere, but which is perhaps felt most intensely in the United States. Though the Dominion is largely affected by this, business is better in Canada than across the border, as the people there do not in general soar so high, or fall so low as their neighbours. Prices are, however, low, business is dull, and competition keen, but it is hoped that when the results of the harvest are realised times will improve.

VICTORIA.

In the colony of Victoria the first legislation on pharmacy was passed in the year 1876, an amended Act was passed in the year 1885, and these were consolidated with the Medical Act in 1890. The administration of that portion of the Pharmacy Act relating to pharmacy is under the control of the Pharmacy Board of Victoria, and the members of the Board are elected by the registered pharmaceutical chemists of the colony. The qualifications for registration are that the person shall have passed a preliminary examination before the commencement of his apprenticeship, and have served for not less than four years as an apprentice; have attended one course of lectures and passed examinations during one session at some school or college of pharmacy recognised by the Board, in materia medica, botany, chemistry, and practical pharmacy; he must also have attained the age of twenty-one years, and have passed examinations in practical pharmacy, and any subject that may be prescribed by the Board with the approval of the Governor in Council. The certificates of the Pharmaceutical Society of Great Britain are accepted as fulfilling all the above requirements.

In the Victorian Act the word "person" is specifically denoted as including any corporation, and this clause has been confirmed by the courts, so that Victorian pharmacists are free from the competition of stores conducted by limited liability companies. It is an offence under the Act for unregistered persons to assume any title, etc., which might be construed to suggest the business of a pharmaceutical chemist, and also for any person, not being a registered pharmaceutical chemist, to carry on business as a chemist and druggist or homoeopathic chemist. The name of any registered pharmaceutical chemist convicted of any felony or misdemeanour may be erased from the Register, whereas in Great Britain the power of the Council of the Pharmaceutical Society is limited to terminating the membership of such a person if he happens to be connected with the Society.

A noteworthy clause in the Act is that which stipulates that every pharmaceutical chemist who has an apprentice shall allow him a reasonable time, during the last year of his apprenticeship, to attend the necessary lectures before registration, failure or refusal to allow such reasonable time being regarded as a breach of the contract entered into. Prescribing and the practice of medicine or surgery by pharmacists are discouraged by a similar penalty (not exceeding £20) to that incurred by an unregistered person acting as a pharmaceutical chemist. At the same time the rights and privileges hitherto enjoyed in that respect are fully secured. As in the British Act, the bona fide business of medical practitioners and wholesale dealers is exempted from interference, but "patent medicines" are not mentioned. The business of a deceased pharmacist may not be carried on by executors, etc., for longer than two months, without special permission being granted by the Board. This clause compares favourably with the so-called "Widows Clause" of the British Act, which permits such businesses to be carried on indefinitely so long as a qualified manager is in charge, and undoubtedly constitutes the weakest point in the Act. Regarding it then from every point of view, it will be seen that the Victorian Act is far and away the best drafted of any in force in English-speaking countries, and nearly approaches the ideal. As it is, the prospects of professional pharmacy in Victoria, in the near future, are very bright and promising.

The foresight and wisdom of those pharmacists who had the framing of the Victorian Pharmacy Act is fully exemplified to anyone who chooses to compare the status of the profession as it exists to-day with what it was before these worthy pioneers took the reins for from the state of a mere trade which all classes could practise, it has emerged into a profession and is recognised as such by all classes of the community, many of the pharmacists of Victoria being gentlemen who hold important public positions, and are the recipients of social distinctions of no mean order.
It will be no exaggeration to say that the pharmacies of Melbourne and the principal cities of Victoria are on a scale of magnificence which equals anything to be found either in Great Britain or the rest of Europe. Encouraged by these results the other Australian colonies have betirred themselves with more or less success to obtain legislation on the same lines, their Acts being in fact a copy of the Victorian, but party interests and the various intrigues which are peculiar to parliamentary life, especially in young and democratic countries, have more or less in all cases prevented those who have devoted their best energies to the cause from fully realising their hopes. Yet it is satisfactory to note that in the various colonies each passing year something more is accomplished, and there can be no doubt that it is only a matter of time when the whole of Australasia will be able to boast of possessing pharmacy laws which shall have placed the profession in its proper position, and so guard the best interests and safety of the public.

The College of Pharmacy of Melbourne, the principal teaching centre, is a large and spacious building, fitted with all modern requirements and possessing a staff of teachers of recognised abilities. It numbers amongst its students many from all the various colonies.

The Pharmaceutical Society of Australasia has its headquarters in Melbourne, Victoria. It was founded in 1857 to uphold the status of registered pharmacists, watch the law relating to pharmacy, advance the study of chemistry and pharmacy, and aid pharmacists or their relatives in case of need. The largest proportion of the members live in Victoria, but others are found in New South Wales, Queensland, South Australia, New Zealand, Tasmania, and Fiji.

WESTERN AUSTRALIA.

At the present time it is open to anyone to establish himself in Western Australia as a pharmacist, without possessing the qualifications needed for the proper discharge of the accompanying duties. However, a Pharmacy Bill passed its second reading in the Legislative Assembly on October 16 last, which adds to and consolidates the existing law regarding the sale of poisons and the business of a chemist generally. It recognises, in the first place, the Pharmaceutical Society of Western Australia, which now numbers fifty-five members and is in a sound financial position. It is to be managed by a council consisting of a president and six other members. In the hands of this council is to be placed the registration of chemists, and no person is to be allowed to carry on the business of a chemist unless he is so registered. Any person who has attained the age of twenty-one years is to be entitled to registration (a) if for at least two years before the coming into operation of the Act he has carried on the business of a chemist within the colony; (b) if he has been continuously employed for two years before the passing of the Act as a dispensing assistant in a chemist's shop within the colony; (c) if for at least three years before the date of the coming into operation of the Act he has been continuously employed as a dispensing chemist in a hospital, benevolent asylum, or other public institution in Western Australia; (d) if for at least four years he has served as an apprentice to a chemist in the colony and has passed the examinations required by the Act; (e) if he holds a certificate of competency as a chemist from any society, board, or college of pharmacy recognised by the regulations. The effect of this Bill will be to bring the law in the colony into a line with that of the United Kingdom and most of the other parts of the empire, and, while raising the status of the profession of pharmacy, will also serve to guard the public against being imposed upon and possibly injured by individuals who have no valid claim to the title of druggist.

SOUTH AUSTRALIA.

The Pharmacy Board of South Australia was established by the Pharmacy Act of 1891, which recognises two classes of registered persons—"chemists and druggists," and "pharmaceutical chemists." As in the other Australasian colonies, names may be erased from the Register on conviction for offences considered by the Board to render the persons unfit to remain thereon. Registration as a pharmaceutical chemist is granted after passing a preliminary examination in Latin, English, and arithmetic; serving a four years' apprenticeship; and passing a final examination in practical pharmacy, chemistry, and any other subject that may be prescribed. The conditions of registration as a chemist and druggist are that the individual shall have been engaged in business as owner or manager prior to the coming into operation of the Act. The certificates of the Pharmaceutical Society of Great Britain are received in lieu of the examination for registration as a pharmaceutical chemist. It is an offence under the Act for unregistered persons to make use of any title, term, or sign, which may be construed to mean that such person is registered as a pharmaceutical chemist, or chemist and druggist. Corporations and joint stock companies are permitted to carry on business under the management of a registered pharmaceutical chemist. Wholesale dealing is not affected by the Act, pharmaceutical chemists in business are exempt from jury service, and poison regulations are presumably relegated to a separate Poisons Act.

NEW ZEALAND.

In this colony there is a Board of Pharmacy consisting of a president and six other members, which is required to keep a register of pharmaceutical chemists, from which names may be erased on conviction of any offence under the Act passed in 1880. The requirements for registration are that candidates must have attained the age of twenty-one years and shall be examined in their knowledge of the Latin language, botany, materia medica, pharmaceutical and general chemistry, and such other subjects as may from time to time be determined by any bye-law. All registered medical practitioners are entitled to be registered as pharmaceutical chemists on application, as are also the possessors of certificates from the Pharmaceutical Society of Great Britain. Any person selling or offering for sale adulterated drugs is considered to have knowledge of the adulteration, unless he prove the contrary. Medical
practitioners and wholesale dealers are exempt from the provisions of the Act, and, in case of the death of a pharmacist, his executors, etc., are allowed to carry on the business for twelve months if it be conducted by a registered person. All titles, names, or signs implying that a person is registered under the Act are protected under a penalty of five pounds. No restrictions upon the sale of drugs and poisons, or the dispensing of medicinal prescriptions are found in this Act, nor is the term "person" specifically defined as including a corporation.

CAPE OF GOOD HOPE.

Pharmacy in this colony is regulated under the Medical and Pharmacy Act, 1891. The Pharmacy Board consists of a president, secretary, and five other members, two of whom are nominated by the governor of the colony, one by the Colonial Medical Council, and three by the chemists and druggists of the colony. Registration as a chemist and druggist is granted on examination, but the certificates of the Pharmaceutical Societies of Great Britain and Ireland are accepted in lieu of examination.

INDIA.

There are no pharmacy laws in India to regulate the sale of medicines and poisons, or to prevent the sellers from being any but qualified persons. The shops are of various kinds, from those of the Europeans in the Presidency towns and chief hill stations down to the small druggist's stall in the bazaar in the "petiah." Some of the best pharmacies are not altogether restricted to the sale and dispensing of medicines, as they often partake of the character of a general store department, and almost every pharmacy has connected with it an aerated water manufactory. Many of the native shopkeepers of Madras trade under the name of a European firm, and some of the shops are owned by proprietors who know little about medicine, the manager being the responsible salesman.

A person who opens a shop for the business of a chemist and druggist is, as a rule, qualified by a certificate granted by the Medical College of Calcutta, Bombay, or Madras. The larger pharmacies are managed by assistants qualified at home, and the owner of a certificate from the Pharmaceutical Society is regarded with more confidence than one with only a local qualification. The certificate of a "chemist and druggist" is given in Madras to the student who attends full courses of instruction in materia medica, chemistry, practical chemistry, and practical pharmacy, in the Medical College. The fee for each course is Rs. 10, and the examination fee is Rs. 25. Students seldom fail to pass the final test after their regular attendance at the lectures. The examinations are not compulsory, in fact anyone may open a chemist's shop as long as he pays the usual trade and professional tax to the municipality.

The British Pharmacopoeia of 1885 is the standard medicine book throughout the country, and whatever drugs or preparations may be introduced in any future British or Imperial Pharmacopoeia, the eastern druggist will only have to order them out from his western wholesale house in the usual way. The retail chemist makes himself as few stock preparations as he can, as he imports his tinctures and ointments direct from England or Germany.

HONG KONG.

The crown colony of Hong Kong is the most easterly of the British possessions, and the city of Victoria contains 250,000 inhabitants, of whom about 3000 are European residents. There are two English pharmacies in Victoria, besides one German and one Portuguese. A large amount of dispensing is done, for none of the doctors do any dispensing themselves, and a great many foreign prescriptions are presented including a large number of American ones, for at certain seasons visitors are constantly passing through the colony. As might be expected in such a malaria-ridden locality, large quantities of quinine, antipyrine, and phenacetin are used, as well as extract of malt and cod liver oil. Native assistants in the European "hongs" get from $10-15 a month; European assistants are paid from $80-130 a month for engagements lasting from 3 to 5 years. Lodging is generally provided, but not board, which, if a mess can be formed, costs from $30-60 a month. Business practically begins at 7 a.m. and finishes at 7 p.m., but on certain days these hours are much shortened. The usual price for a bottle of medicine or a box of pills is a dollar. There is no poison law proper in Hong Kong, and anyone can buy the most dangerous drugs, such as datura, gelsemium, arsenic, etc., at any of the native drug stores for the mere asking.

JAMAICA.

The sale of drugs and poisons in Jamaica is regulated by the Law of 1894, the term "drugs" there including "medicines, compound medicine, or medicinal preparation," whilst "poison" includes "any poisonous substance, poisonous drug, or preparation containing a poison" scheduled under the Law. Parts 1 and 2 of Schedule A correspond with those of the British schedule, but are more extensive in each case, carbolic, pyrogallic, and mineral acids and many other substances not scheduled here being included. The conditions under which poisons may be dis-
pensed or sold are very similar to those prevailing in this country, but every sale of poison must be recorded in "The Sale of Poisons Book." Unwholesome or adulterated medicines must not be sold, or heavy penalties are incurred.

The pharmacies are run on very much the same lines as the drug stores in America, and are all fitted with American aerated water fountains, placed in some conspicuous part of the store. The proprietor deals in all the articles a grocer would in England, and keeps a large staff of hands for that purpose, at least as far as the Kingston shops are concerned. The amount of dispensing done is very small indeed, as all the Kingston medical men do their own dispensing, some of the busiest of the doctors having three or four men dispensing for them all day. It is very doubtful whether more than one in twenty of these men are properly qualified under the Jamaica Law, yet it is through them the great bulk of medicine finds its way into the hands of the public.

There is no preliminary examination, but candidates for a licence under the Law must submit certificates of moral character and respectability, and of general education. The qualifying examination itself consists of questions in elementary Latin, the recognition of drugs and chemicals at sight, a general examination on the Pharmacopoeia, and the dispensing of prescriptions. Candidates must have attained the age of twenty-one years, and have been engaged in the practice of pharmacy for two years, the last of which must have been with a registered medical practitioner or a licensed dispenser. Pharmacies must not be kept without a licensed person in charge and, in consideration of this, exemption from jury service is granted. In addition to the specific penalties for the various offences under the Law, conviction in any case may be followed by the suspension of the licence for a period not exceeding six calendar months.

DEMPERARA.

At present there are no restrictions whatever under which pharmacy is conducted in Demerara, nor are there any regulations as to the qualification of those practising pharmacy, so that the most illiterate Chinese or the most ignorant of Africa's able sons can become "chemists and druggists," and keep open shops for retailing or dispensing medicines to their fellow-creatures, merely by paying for the necessary licence. Certificates of any kind are of no moment whatever. The chemists and druggists have formed an association which has, amongst other things, endeavoured to get a law passed preventing anyone selling medicines unless he has been engaged by a chemist for a certain time, and has passed an examination held by the Association, but, so far, unsuccessfully, as there has been great opposition from the Medical Council, which claims that it and it only has any right to issue such certificates. Not only is there no protection whatever for chemists and druggists, but they suffer under unfair restrictions, as may be judged from the fact that within recent years a law was introduced by a Government official and passed by the Legislative Council, prohibiting chemists and druggists, under penalty, from retailing a single grain either of opium or "ganjah" unless prescribed by a medical man, but giving free scope to any other man—no matter what his profession may be—to sell it ad libitum. There are several first-class pharmacies in Demerara, and chemists as a body are very much respected by the people, and there is all the more reason therefore why the Legislative Council should help them to become an organised body with their own laws, so as to protect the people from the effects of ignorance on the part of unqualified individuals.

TRINIDAD.

Druggists are admitted to practise their trade in Trinidad on the licence of the Medical Board, which consists of all the qualified medical men practising in the island, and is governed by a Council elected for three years, consisting of president, vice-president, secretary and treasurer, and three other members. The licence of this Board is granted to any person possessing a certificate entitled him to practise as a chemist and druggist or as an apothecary in any part of the United Kingdom, on proof that he is the person represented in the certificate. Druggists and assistant druggists are admitted to practise under a licence granted after a local examination held under the auspices of the Medical Board. The local "Sale of Poisons Act" is similar in its conditions to that of the United Kingdom.

There are very few medical men who compound their own medicines, or who keep a dispenser, and the patients' friends choose their own druggist from among those practising. American and French preparations and proprietary medicines have a large sale. English goods are not pushed to the same extent as American. Prescriptions are charged for at rates ranging from 2s. to 4s. each.

BERMUDA.

In Bermuda anyone can use the name of pharmaceutical chemist if he chooses to do so. Poisonous nostrums, including all sorts of vermin killers, are mixed up indiscriminately with sweets, etc., in other shops than that of the druggist.

The druggists are socially classed among the small shopkeepers, not having undergone any special training other than that of buying and selling.

It is compulsory that professional men, including the medical men and the dentists, shall, before practising, show that they have the necessary training by producing diplomas from recognised bodies, but no proof of ability is required by the man who dispenses their prescriptions.

ITALY.

The position of pharmacy in Italy just now is a peculiar one. The latest law allows every qualified pharmacist the right to open a pharmacy, but it also allows those already established the right to proceed against new-comers for an indemnity for the damage done to their business. When a new man opens a pharmacy the existing pharmacists who think themselves injured protest; a commission is then formed of high sanitary officials of the province, generally assisted by a doctor, and this commission decides the amount to be paid to the several protestors. Strange to say,
THE PHARMACEUTICAL JOURNAL AND TRANSACTIONS. (December 1, 1894

none but protestors get indemnified; if a man lives next door to the new-comer he gets nothing if he does not protest, but of course he invariably does so. The time taken by the commissioners to decide varies, according to their fancy, from three months to three years, and is usually nearer the latter. It is obvious from the above that the Italian Government wishes the pharmacists to be free, but does not wish to buy out existing interests, so the newcomers have to take the burden on their own shoulders. The removal of restrictions as to the number of pharmacies is already bearing bad fruit, for "cutting" is beginning. An official tariff is published of the retail price of all medicines known to the direct descendants of the Lateins, and, though one may charge less than the stated prices, one cannot charge more. Many are now charging less, and further ill effects may follow.

GERMANY AND AUSTRO-HUNGARY.

Throughout Germany, Austria, and Hungary the practice of pharmacy has been from time immemorial subjected to stringent regulation by the governing authorities. In the interests of the public, qualification by study, technical training, and examination has been required, the mode of conducting business has been controlled by periodic inspections, and the charges for medicine, etc., have been regulated by a fixed tariff. The interests of pharmacists have also been protected by the limitation of the number of pharmacies in proportion to the population by restricting to them the dispensing of medicine and the sale of drugs or medicinal preparations, and by the prohibition of secret remedies. Under these conditions the occupation of the "apotheker" was largely of a professional character, and he held a position analogous to that of medical men or members of other professions. Of late years, however, the growth of the more purely trading portion of the business has been disproportionately rapid, the establishment of factories where pharmaceutical preparations are manufactured on a large scale, and supplied at a lower cost than they can be made for on a small scale, the introduction of specialties and their recommendation to the public by means of advertisement, have, together with other antagonistic influences, effected a great change in the conditions under which the practice of pharmacy is carried on in these countries. In that respect the situation is approximate to that which prevails in this country, and the trading side of the business is becoming more prominent. In many instances, however, this part of the business is kept strictly separate from the work of dispensing, to which a distinct apartment is allotted, entirely away from that in which retail trade and the sale of druggists' sundries is conducted.

FRANCE AND BELGIUM.

An attack is threatened upon the position of French pharmacists, the Congrès des Sociétés de Secours Mutuels having decided to seek to obtain powers to establish pharmacies for the supply of medicines to the members of the societies. Such pharmacies have been in operation in Belgium since 1882 and have been found to attract considerable custom from the general public, in addition to those for whose special benefit they were ostensibly founded. In self-defence the pharmacists of Brussels, the place chiefly affected, formed last year a pharmaceutical federation of individuals keeping open shop exclusively, its objects being to counteract the effect produced by the so-called "popular pharmacies," and to defend pharmacists' professional interests generally. A special tariff was drawn up by the federation, but proved a failure. Then, however, numerous other societies not affiliated to the Belgian Fédération des Sociétés de Secours Mutuels, applied for a similar privilege with regard to the establishment of pharmacies, but this attempt the committee of the pharmaceutical federation was able to defeat just before the latest dissolution of the Belgian Parliament. It is anticipated that a fresh attempt will be made in the same direction, and, meanwhile, the pharmacists are resting on their victory, having also achieved the useful result of combining themselves into a compact body. It is now proposed, according to the Moniteur de la Pharmacie, to take similar action in France, and perhaps prevent the threatened evil at the outset, by founding a Fédération Générale des Pharmaciens Français, which shall occupy itself solely with the defence of professional interests.

UNITED STATES.

Of the forty odd pharmacy laws on the Statute Books of as many States of the Union, twenty recognize diplomas of colleges of pharmacy; fifteen recognise both medical and pharmaceutical diplomas. In these States, British certificates are more or less recognised for registration. In five of the most populous States—Massachusetts, New York, Pennsylvania, Ohio, and Illinois—no diplomas are recognised, examination by the Board of Pharmacy being the requirement for registration, except a provisional registration in Illinois after five years' experience in pharmacy. The pharmacy laws have protected the public against incompetent dispensing, have afforded medical men fair qualification in the compounding of prescriptions, but have reduced the pharmacists to practically the same level before the law, the public, and the medical profession, so that there is no further incentive for a young man to extend his studies in pharmacy beyond the meagre modicum required by the various Board Examinations, which is but little higher to-day than ten to fifteen years ago, when the first laws were enacted. In the State of Ohio there are no less than seven schools, and the condition of affairs is somewhat similar in other States. The students usually go to the college where they can get through the quickest. The "diploma mills" are therefore largely patronised. Pharmacy must, of necessity, undergo a radical change in the States, and it has already entered upon the starving-out period. Eventually all the States ought to insist upon registration of apprentices; two classes of establishments—drug stores and official pharmacies; registered assistants; registered pharmacists, who may "run a drug store"; registered pharmaceutical chemists to conduct official pharmacies.
THE PHARMACEUTICAL SOCIETY'S New Hall and Laboratories in Edinburgh.

The extension of the Pharmaceutical Society's premises in Edinburgh has been rendered necessary by the increase in the number of candidates presenting themselves for Examination before the Board of Examiners for Scotland, and by the improved and extended system of practical and oral examinations. The present Hall was also found inconvenient and unsuitable for meetings when well attended.

A re-adjustment of the old premises is contemplated after the new are finished. The present Board Room will be the Library, and the ground floor entirely reserved for the Museum. The present Laboratory will be the Business Room and Office.

The additions have taken the form of a one-storied building, covering the entire background of the tenement, which was in 1884 acquired by the Society and converted for its uses. They comprise a Hall, space between the side boundary walls. Its height to the ceiling is 16 feet. The wall surfaces are unbroken to the height of the frieze, but to a height of four feet they are tastefully panelled in wood. The ceiling is of plaster, and is relieved by having the constructive beams of the roof defined. The compartments so formed are panelled and moulded, the whole descending upon the cornice in cove form. Carved scroll trusses spaced in the frieze receive the ends of the beams. The lighting is from the top. Three of the ceiling compartments are filled with obscured glass, which receive the light from a like number of skylights in the roof above. By the inner glass frames cold draughts from the skylights will be checked. For artificial lighting, in the Hall and throughout the new buildings provision has been made for electric appliances, which it is expected will, at an early date, be available, but meanwhile large sunlight burners have been introduced. These are likewise constructed to exhaust the vitiated air by promoting an upward current. Fresh air is admitted from special inlet openings under control. For convenience of arrangement, light chairs instead of forms have been provided for seating, the accommodation being equal to 250 persons, after allowing ample space for the chairman's platform at one end.

The Hall is very appropriately and tastefully decorated. The walls are papered with richly-coloured design paper, the ceiling is picked out in soft, light colours, and the frieze enriched with hand-painted ornament of suitable design. The woodwork is richly stained and varnished, the effect throughout being light, finished in appearance, and comfortable. The Hall is well heated by means of hot water radiators, with controlling tapes to shut them off separately if desired. At the further end of the Hall a door leads to the corridor at the back, which communicates with the Dispensing Laboratory and the Chemical Laboratory. The Dispensing Laboratory is reached first. It is a large rectangular apartment, lofty, and well lighted. The appointments are most complete, and everything is of the newest style. Accommodation is provided for twenty-four students, each having a liberal allowance of counter space. Within the
counter, in a series of compartments, each student has all the requisites for dispensary work, and above the counter there are ranges of graduated shelving for bottles. Special chemical fume chambers are constructed in the main walls, where exhaust tubes of suitable altitude are situated.

The Chemical Laboratory is of irregular outline on the plan, following an L shape—a small room appropriated as a gentlemen’s lavatory occupying the re-entering angle. Accommodation is found for twenty-four students, who have each sink, cupboard, and bottle-shelving, with all modern appliances for carrying out the requirements of examination work. General cleansing sinks, chemical fume chambers, and other requisites are provided for in the most liberal manner. In this room is the stove for the general heating system by radiators, already referred to. Like the main Hall, the internal construction of the Laboratories is carried out with panelled ceiling, but on a much simpler scale. For the same reason as applies to the main Hall, namely because of the surroundings of the building, the lighting is from the ceiling, but, as in the Hall, double sashes are provided to prevent air currents and maintain a more uniform temperature. The only exposed elevation of the new buildings is that towards Duke Street Lane. It is treated appro-

The New Examination Hall.

appropriately with simple detail of the Renaissance period. The drainage works have received special consideration, the system for the chemical working being in specially constructed pipes, and quite separate from the system for the ordinary requirements of the building.

The Dispensing Laboratory.

The Chemical Laboratory.

The mason work has been executed by the late Mr Hugh Macintosh, the carpenter work and fittings by Messrs. John Davidson & Co., the plumber work by Messrs. Barton & Sons, the electric light fittings by Mr. Matthew Buchan, and the painting by Mr. R. G. Rees.

The architect for the work is Mr. Hippolyte Blanc, A.R.S.A., Edinburgh.
THE REMUNERATION OF THE PHARMACIST.

Of all the questions directly affecting pharmacists there is none of more perennial interest or of more pressing importance than that concerning the manner and extent of the remuneration to which they are entitled for the services rendered by them to the public. It may, moreover, be asserted with confidence that there is no problem which is less likely to be solved to the general satisfaction. For, after all, in the absence of any legally established tariff of charges, it is peculiarly a matter for each individual to settle for himself what remuneration he will accept. Combinations to maintain any particular standard of prices must, in the very nature of things, fail to be effective except within extremely limited areas. In every trade or profession the same rule holds good; the remuneration depends primarily upon the individual receiving it, and in some degree upon the class of business carried on, as well as the district or class of people catered for.

The chief factor in the problem is, of course, the individual most directly interested in the results, for he is able to a considerable extent to influence the other factors by deciding where and how he will carry on business, as well as what kind of business it shall be. Even when his choice is not so free, it must always be within his power to modify his surroundings by his personal influence, the extent of the modification depending upon his business aptitude and previous training. Then, although, as already remarked, it will always be difficult to maintain any general standard of remuneration, this difficulty should not be permitted to interfere with the maintenance of a definite minimum charge, which must never be an unprofitable one. The pharmacist's charges should be classed under three distinct heads:—The highest remuneration for purely professional work, such as dispensing and analysis; the next for semi-professional work, such as the supply of chemicals and drugs which he personally guarantees; and the lowest for purely trading operations, such as are involved in the sale of articles which he simply hands over in the same condition as he receives them. This arrangement is the only rational one for the pharmacist to adopt, and, if faithfully adhered to, would enable him to avoid doing anything likely to conflict with the interests of his fellow-craftsmen.
But this question of remuneration does not affect pharmacists established in business directly only; it affects them indirectly in its bearing upon those whom they employ. There is little reason to doubt that if every registered individual not in business on his own account were assured of more satisfactory remuneration and generous treatment generally at the hands of bond fide proprietors of pharmacies, considerable advance would be made towards the great difficulty of company-trading being overcome. As clearly stated in the excellent address recently delivered by Mr. Sutherland (ante, p. 426), pharmacists generally must be prepared to offer to their assistants better terms than have been customary. This they ought to do if they respect and would maintain the status of their profession, for very decency's sake no less than in their own interest. There is no reason why, under greatly improved conditions, many assistants should not be content, as in other walks of life, to remain more or less permanently in that position. There are none too many legally qualified assistants in the country, and one very beneficial result of such a change as suggested would be to check the tendency to rush prematurely into business, and so relieve the overcrowding that is at the present time sadly too manifest.

**ANTITOXINS.**

The more recent issues of the medical journals contain reports of further cases of diphtheria treated with antitoxin. In some it is expressly stated that the diphtheria bacillus has been found in cultures, but in many instances this has not been practicable. Where the characteristic membranes, glandular swellings, albuminuria, and depression are met with, that is, in pronounced cases, there can be, in the hands of competent medical men, no need for bacteriological diagnosis; but where the signs are less well marked there is a possibility of mistakes, and, according to the view we have already expressed, we hope that in our London hospitals the bacteriological test will in future be applied. The method of doing this is not difficult, and the diagnosis of the bacillus in cultures is easy on account of the rapidity of growth which the diphtheria bacillus shows at suitable temperatures and in suitable media. A sterilised platinum needle is rubbed on the suspected membrane, and plunged in the usual way into a jelly made with peptone-bouillon and agar-agar; to this 5 per cent. of glycerin is added. Sheep's or bullock's serum, fixed at 70° C., serves equally well. At a temperature of 37° C. in these media, small white colonies begin to develop on the surface and in the needle track so rapidly, that they are visible in twelve hours, and in fifteen hours are sufficiently advanced to afford material for cover-glass preparations, which should be stained with methyl blue dissolved either in 5 per cent. carboxylic acid solution or in 01 per cent. solution of caustic potash.

In order to summarise the more recent experiences with antitoxin treatment, we have consulted the London medical journals, to which we are indebted for what follows:

It seems right to notice German results first, seeing that Behring crowned the work of Löffler and Roux by the discovery of the antitoxin. Many of the German hospitals have published hopeful statistics, and the antitoxins prepared either under the supervision of Professor Behring or made according to his directions by Aronson have been largely used outside Germany; for instance, Professor Boxer publishes the results of thirty-five cases treated by Professor Behring's serum, and resulting in five deaths. Of the thirty children who recovered, intubation of the larynx was performed in twelve. Twenty of the cases were under four years and seven under two. Thus the result must be regarded as exceptionally good considering the age of the children. We may note in passing that in two of the cases no growth of bacilli was obtained, although all the clinical characters of the disease were present. Thus it seems the bacteriological test should not be relied on by itself.

In Germany polemical articles have already appeared in the magazines, Professor Behring upholding the virtues of the method, whilst Professor Rosenbach, on the one hand, and Drs. Gottstein and Schleich, on the other, criticise the method and the published statistics adversely. It is noteworthy, too, that Löffler has recently insisted on the importance of local antiseptics in diphtheria.

In France the record made by M. Roux of two hundred cases treated with serum prepared by him is chiefly relied on. It is to be noted that all the ordinary measures are equally insisted on, whether the antitoxin treatment is used or not. In Paris, it seems, cases of diphtheria not treated with antitoxin show the high mortality of 50 per cent., and in the two hundred cases in which antitoxin was used the mortality was 24 per cent. To make these figures more instructive it is advisable to add that in cases where tracheotomy was necessary the percentage of deaths was 73.19 per cent. without antitoxin, and 49 per cent. when the antitoxin was used.

In England Aronson's antitoxin has been chiefly employed. Many medical men have sent, with admirable impartiality, reports both of recovery and of death in cases in which antitoxin was administered. Mr. Saw, house physician at St. Mary's Hospital, has published a series of five cases in which antitoxin was used, and all of which
required tracheotomy. All these patients, young children, recovered. We understand that since the supply of antitoxin failed several deaths have occurred at the same hospital in cases of diphtheria in children. At St. Bartholomew’s Hospital good results have also been obtained. We are glad to see that antitoxin, prepared at the Institute of Preventive Medicine under the supervision of Dr. Ruffer, has already been applied therapeutically, as in the following instance reported by Dr. Frith (Woolston): —A child, age eleven, presented unmistakable evidence of the disease. The tonsils and uvula were covered with membrane. 5 C. c. of antitoxic serum were injected. The strength of the serum had previously been tested by Dr. Wright of Netley, by injecting into guinea-pigs measured quantities of toalbumin with the antitoxin, and it was thus found that 0.001 C. c. of this serum neutralised 1 C. c. of the toxin. The remedy in Dr. Farr’s case appeared to have a good effect; within a few hours the patient’s general condition improved considerably, and recovery was rapid.

It must be said that a review of the cases published in this country is most distinctly in favour of the method. With regard to the antitoxin of tetanus, the prospect is not so hopeful.

Dr. C. E. Douglas relates a case of tetanus in which, in conjunction with salicylamine of eserine (½ gr.) and 20 gr. doses of chloral hydrate, Tizzoni’s antitoxic serum was used. A gardener, aged sixty-three, had been bitten by a dog, and five days later, when the wound had healed, stiffness of the jaw was observed. Four days after this, pain and rigidity in the muscles of the abdomen and back came on. The symptoms became daily worse, severe spasms with opisthotonus supervening. Quarter-grain doses of morphia were added to the treatment. On the seventh day after the onset of treatment “half a tube” of Tizzoni’s dried serum was dissolved in water and injected by seven punctures into the muscles of the thigh and back, strict antisepsis being employed. In spite of stimulants the man died the same day. This case may be taken as one of many which go to show that the antitoxin of tetanus is quite useless except when employed at the commencement of the disease. Dr. Douglas mentions a point of practical importance, namely, that dried serum dissolves very slowly in cold water. The directions given for use of the antitoxin state that the substance “decomposes under a temperature even a little elevated.” Dr. Douglas suggests that since the normal temperature of the horse is about 101°F., water at 100°F. would probably not injure the antitoxin and would dissolve the antitoxin serum much more readily than cold water. It is to be hoped that the antitoxic serum for tetanus will shortly be produced from an English source, so that the remedy may be tried earlier in the disease, and thus, before judgment is finally pronounced, this antitoxin would have a fair trial in this country, although not so much is to be hoped from it as in the case of the antitoxin of diphtheria. Indeed, it has been said that as soon as the first symptom of tetanus is present the time for preventive treatment has passed. If so, preventive measures for tetanus must be limited to antisepsis. In many cases of lacerated wounds dirt is, however, forced into the tissues, and antisepsis is impossible unless immediate amputation is performed. As an alternative to this a further trial of the antitoxin of tetanus, which, in experiments on animals, has been found to work so well, is emphatically called for.

THE REVISION OF THE PHARMACOPEIA.

That the forthcoming issue of the British Pharmacopoeia should be as comprehensive as possible, and include such remedies as have been proved to be universally useful, is a proposition which must commend itself to everyone capable of forming an opinion on the subject. But, considering the knowledge we at present possess, it is not by any means so self-evident that the time has arrived for the production of a pharmacopoeia which would be “imperial” in the sense of being equally adapted to the requirements of every part of the British empire. There are so many difficulties to be overcome, that the result, if that task be undertaken, is almost sure to bring about disaster, or at least confusion, a most undesirable element in such an important publication.

The important factor of climatic conditions alone raises a barrier which will be found very difficult to surmount, for in the case of ointments, for instance, formulae which may be most suitable for the colder regions of Great Britain would probably be wholly unsuitable for a climate like that of India or the northern parts of Australia. But even leaving out of account this and any minor difficulties which may suggest themselves, it is necessary to consider the more important question whether we really know sufficient about the various colonial productions, the use of which for medicinal purposes has up to the present been advocated by our colonial friends. Certainly much yet remains to be found out. We would be sorry to write anything to disparage the earnest and patient researches of colonial scientists, for the time has arrived when their labours are beginning to bring forth important results, and the powers that be will do well to consider carefully the various valuable suggestions that are to hand from colonial centres in connection with the new edition of the Pharmacopoeia.

We are well aware that in the Australian colony
of Victoria a great deal of both Government and private money has been spent in the growing of opium, the production of essential oils, and various medicinal plants, and that the medical faculty of that colony may be said to unanimously approve the colonial grown articles. Therefore, it appears fair and reasonable that in such cases as these the use of local productions for medicinal purposes should be officially recognised so far as the interested colony is immediately concerned. But cannot all this be amply provided for by supplementing the matter of the British Pharmacopoeia with footnotes in reference to particular official drugs or preparations, and with an appendix including the more valuable unofficial productions? This appears to be all that is practicable or that can be desired, and it would be a great step in advance towards the future. That in this sense the "imperial" adaptation of the national pharmacopoea may become an accomplished fact in the future is quite within the range of possibilities; but to fulfil the requirements of all conditions it must be a thing of slow and sure growth, for it is too large and important a subject to admit of hasty compilation. From the very nature of the book it must continue in the future, as in the past, to be a work in which changes will always be more or less required, and the information it contains must of necessity be at most, comparatively speaking, complete only up to the date of its publication.

The general impression given by the majority of the communications we have received on this subject is that the prevailing notions with regard to the next revision of the British Pharmacopoea are extremely vague and indefinite. We are pleased, therefore, to be able to publish the reference to the matter made by the President of the General Medical Council, Sir Richard Quain, Bart., in his address at the opening of the fifty-seventh session on Tuesday last. It will be noticed that a full statement concerning the various communications received from the colonies, etc., will shortly be submitted to the Pharmacopoea Committee by Professor Attfield, and the details of this statement we hope to be able to publish in our next issue.

"ANTITOXIN" AND "ANTITOXINE."

In reference to the application of the term "antitoxin" to the prepared serum used in the treatment of diphtheria, we learn from the proprietor of an article designated "antitoxine" that he claims priority in the use of this word, and that he had registered it as a trade mark in the United States as far back as October, 1892. It must, however, be stated that, before the time mentioned, the term "antitoxin" was in general use by bacteriologists in relation to the production of immunity.

PROPRIETARY MEDICINES IN FRANCE.

The proposed alteration of the French law relating to foreign proprietary medicines, according to which the statement of the active principle and dose on the label is to be required as the only condition of their sale, is calculated to have an important influence upon the trade in such articles, and, as pointed out by Jungfleisch, to facilitate their sale to the disadvantage of French pharmacy. Under the existing law no medicinal preparation, considered by the authorities to be of a secret nature, is allowed to be imported or sold. Any question requiring to be determined in regard to such articles is submitted to investigation in the laboratory of the Ecole Superieure de Pharmacie for the information of the Minister of Commerce, and in that way foreign quack medicines are kept out of France.

AN INTERNATIONAL CHEMICAL CONGRESS.

It is suggested by the American Chemical Society that committees should be appointed by the various chemical societies in other countries, to consider the desirability and practicability of organising a series of international congresses, at which the chemists of various nations could regularly meet together for the discussion of subjects of common interest. The interest manifested in the International Chemical Congress held in connection with the Chicago Exposition, and the fact that, in addition to similar organisations in medicine and pharmacy, geologists have also established a triennial international congress, justify the anticipation that such periodical meetings of chemists may also be feasible. Those interested in the project are requested to communicate with F. W. Clarke, U.S. Geological Survey, Washington, U.S.A.

AUGUST KAUKERT.

With profound regret we record the death, at the age of forty-seven, of August Kaukert, one of the Burgomasters of Elberfeld, and a most active member of the German Apotheker Verein, who had for many years occupied the position of a member of the Vorstand, or executive, of that body. Herr Kaukert will be remembered by several of our readers who have attended the meetings of the Apotheker Verein, and also as having been present on the occasion of the celebration of the jubilee of the Pharmaceutical Society in 1891.

SUBSCRIPTIONS TO THE JOURNAL.

For the convenience of those who do not receive the Pharmaceutical Journal regularly, and who desire to become subscribers, an order form is enclosed with the present number. The Journal is supplied from the Office, 6, Serles Street, Lincoln's Inn, London, W.C., post free to any address at home or abroad for twelve months, on receipt of 10s. 6d.
MISCELLANEOUS NOTES.

We are informed by the Society’s Solicitors that a formal intimation has been received by them purporting that Mr. Mandall will withdraw from contesting the petition of the Society for the revocation of the patent No. 6178 of 1893, described as for “A New and Improved Utilisation of Liquorice and other Ingredients for the manufacture of certain Medicinal Compounds.”

A grant of one thousand pounds has been made by the Goldsmiths’ Company for investigating the antitoxin treatment of diptheria, and supplying anti-diphtheritic serum amongst the poorer classes of the community. The Laboratories Committee of the Royal Colleges of Physicians and Surgeons has undertaken the administration of the grant.

The Naples correspondent of the Daily News states that the anti-diphtheritic serum received at Genoa from the Bannino Institution has given very unfavourable results, the Genoese physicians being much disappointed. The Venetian doctors, also, are equally dissatisfied, many cases treated with the supposed remedy having resulted fatally.

The Italian Government is said to have issued a decree offering prizes of £600, £250, and £175 sterling to persons who shall open factories for the preparation of citric and tartaric acids in Sicily. To obtain the first prize both citric and tartaric acid must be made, the former in a quantity of at least half a ton a day. Applications for the prizes must be made not later than December 31, 1896, and the works must be in operation not later than February, 1896, in which year the Minister of Agriculture will distribute the prizes.

A Co-operative Society of pharmacists has been formed in France to manufacture iodine and its compounds, the supply of which will be strictly confined to the shareholders.

According to the Pharmaceutical Era, the members of the class attending the Jefferson Medical College at Philadelphia, have decided when they graduate in 1897, to use the metric system in writing their prescriptions.

The postal authorities announce that on and after January 1, post cards, book packets, newspapers, and sample packets will be re-directed free of charge, under the same conditions as letters. Parcels, however, will still be liable to additional charge for re-direction.

Mr. Thomas Bateson, pharmaceutical chemist, Kendal, has been placed upon the Commission of the Peace for the borough of Kendal. Mr. Bateson is Vice-Chairman of the Kendal School Board, and has just been re-elected unopposed to the Town Council. He will be remembered also as a candidate for a seat on the Pharmaceutical Council in May last.

Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE EXECUTIVE OF THE NORTH BRITISH BRANCH.

A meeting of the Executive of the North British Branch was held in the Society’s House, 36, York Place, Edinburgh, on Thursday, November 29, at 12 noon, Mr. Michael Carteigh, President, in the chair.

The minutes of the last meeting were read and approved.

The Report of the General Purposes Committee, consisting of minutes of meetings held on October 9 and 16 and November 13, were read. From the report it appeared that a tender for heating new hall and laboratories by hot-water radiators for £30 15s., by Messrs. Mackenzie and Moncur, had been accepted; a tender by the York Glass Company for special recess labelled reagent bottles for Chemical Laboratory, at 18s. per dozen, was accepted, and it was resolved to procure recess labelled bottles, etc., for Dispensing Laboratory; a tender for chairs for hall at 4s. 6d. each by J. & T. Scott was accepted; a tender for painting hall and laboratories by Mr. Ross for £4 14s. 6d. was accepted; a tender for enamelled tile dado in staircases for £56 by Messrs. G. & H. Potts was accepted; also a tender of £57 for gas fittings in hall and laboratories by Messrs. Barton & Son; and a supplementary estimate to complete electric light fittings for £5 15s. by Mr. Buchan were accepted. It had also been arranged to suggest to the Council, and the Council had directed, that there should be an opening ceremony in the form of a reception and conversations on the evening of November 30. The Committee had also called a general meeting of the trade which agreed to have a dinner of Scottish pharmacists on the evening preceding the official opening of the new premises.

The report was unanimously adopted.

By request of the President, Mr. Laidlaw Ewing explained the progress made with the buildings and the arrangements for the official opening on the following night. The Executive then went into committee to consider the report of the Special Committee appointed to consider names for the Board of Examiners. On resuming it was reported that Professor Patrick Geddes, Dundee; Professor John Gibson, Edinburgh; and Messrs. Peter Boa, David Brown Dott, and Jonathan Innes Fraser, Edinburgh; James Jack, Arbroath; Thomas Maben, Hawick; and John William Sutherland, Dumfries, would be selected for appointment by the Council as members of the Board of Examiners for Scotland for the year 1896.

Votes of thanks to the retiring examiners, Messrs. Nesbit and Gibson, were carried by acclamation.
LIVERPOOL CHEMISTS’ ASSOCIATION.

The fifth general meeting of the 45th session was held on Thursday, November 22, the President, Mr. J. J. Smith, in the chair.

A conversation followed a question by Mr. A. S. Buck respecting the effect of a moderate heat upon Papparin in making the compound granular.

The respective value of ointment of hore acid of different degrees of hardness, and of gelatin of zinc, and other preparations, were spoken of by Mr. C. Hanson, as applications to the face of a small-pox patient. The medical attendant had tried several, and had found a zinc gelatin most effectual.

Mr. T. H. Wardleworth contributed a highly interesting paper upon “Some Objects of Pharmaceutical Interest in the Liverpool Museum.” By the courtesy of the curator of the museum the lecturer was able to illustrate his remarks by means of a large number of specimens which were lent for the occasion. Egyptian antiquities were first dealt with. Then, in the Assyrian section, it was shown that the treatment of diseases was of very ancient origin, and a prescription copied from a tablet which contained thirty-four ingredients, was read in English. Coming to the Roman section, many curious mortars were exhibited, which, from their uneven surfaces, had been well used, and had doubtless been employed in the preparation of medicines. A small mill, used in the early eighteenth century for spices, etc., was also shown. Finally, poisoned darts and arrows claimed attention, including specimens from British Guiana, Boesmen, Borneo, and Gaboon.

Mr. E. Cox followed, and dealt in a most interesting manner with the archeology of Liverpool and neighbourhood.

Several of the points were freely discussed, and both essayists were commended in the highest terms, not only for the interesting character of their communications, but also for the ability with which the subjects had been placed before the members.

PARLIAMENTARY AND LAW PROCEEDINGS.

POISONING CASES AND INQUESTS.

POISONING BY LAUDANUM.

Thomas Henry Byard, aged 45, of Bresky Street, Leicester, died on Sunday, November 18, from the effects of laudanum, self-administered. Verdict: “Suicide whilst temporarily insane.—Leicester Daily Post.”

SUGGESTED POISONING BY PEPSIS ACID.

Dr. Thomas Joseph Redhead, of Hedon Road, Hull, died on Tuesday, November 20, presumably from the effects of pepsis acid, self-administered.—Yorkshire Daily Post.

POISONING BY CARBOLIC ACID.

William Allcock, aged 14, died at Birmingham last week after taking carbolic. Verdict: "Suicide whilst suffering from emotional insanity." The jury expressed the opinion that carbolic acid should be scheduled as a poison.—Daily Chronicle.

POISONING BY A LIMEMENT.

Isaac Moore, aged 89, died at Heanor on Sunday, November 11, from the effects of ammonia contained in a liniment which had been inhaled inadvertently. Verdict: "Death from enfeebled body, accelerated by drinking liniment."—Nottingham Daily Express.

REVIEWS AND NOTICES OF BOOKS.

The editors of this work refer in their preface to several circumstances which have necessitated a more than ordinary revision of its contents. Among these, the alterations in the United States Pharmacopoeia, amounting in some respects almost to a revolution, and the introduction of new remedies, have been the most important. The official adoption of the metric system of weights and measures, and of modern chemical and botanical nomenclature, has also occasioned corresponding changes in the Dispensatory.

But the general plan is still the same as in the earlier editions, the object being to present an account of medicinal substances in the state in which they are met with in trade, and to teach the modes in which they are prepared for use.

The work is therefore to be regarded as a commentary upon the Pharmacopoeia of the United States and the British Pharmacopoeia, with such preparations of the German Pharmacopoeia and French Codex as are generally used in the United States. In the first part, occupying 1480 pages, all the remedies recognised by either of the two pharmacopoeias used by English-speaking people are discussed. Part II. includes the national formulary issued by the American Pharmaceutical Association, and articles on non-official drugs and preparations. The section treating of drugs and medicines not official, extending over 238 pages, contains about one thousand additional separate articles, in which the information as to new drugs and chemicals, etc., requisite for practical purposes is condensed as far as possible. In Part III are considered the tests and test solutions of the two pharmacopoeias, weights and measures, the art of prescribing medicines, and other cognate miscellaneous matters.

The glossary of terms used to define the action of remedies has been retained, and as the work is intended for use by medical men as well as pharmacists, an index of diseases is added, with statements of the corresponding remedies. This is placed at the commencement of the volume to avoid confusion with the general index.

In the main part of the work the alphabetical arrangement has been adhered to as most suitable for a book of reference of an encyclopedic character. To gain the space necessary for the insertion of new matter without unduly increasing the size of the volume, the size of the pages has been increased and the matter of the second part has been printed in smaller type.

Much labour has evidently been expended in bringing up to date the information relating to different drugs, and some of the data in the last edition of the pharmacopoeia have been corrected, as, for instance, the statement that codeine does not act upon litmus paper.
The articles on vegetable materia medica are of very unequal merit. The article Cinchona, as might be expected from Professor H. H. Rusty, is carefully written, and bears the imprint of thorough knowledge of the subject, embodying the observations made by him in South America and the London drug market. Some of the shorter articles such as Urtica are brought quite up to date. Others have evidently passed the eye of the reviser of the proof-sheets with their mistakes unnoticed, thus Acetum hymo- tosium is said to "probably yield much of the aoonite of commerce;" Saigon cinnamon is "derived from Cinamomum longi;" Piper ribesoides is written P. sheroides; Illicium majus still appears as I. magus, and no reference to either it or I. griffithii is made in the text, nor is the reader given to understand that the illustrations are borrowed from an article by Holmes in the Pharm. Jorn. on Star Anise. Sagapenum is stated to be the produce of a "well known" Persian plant; the chemistry of cinnamon oils is by no means up to date, and the article needs re-writing in a future edition.

On the other hand, the majority of the articles show a careful discrimination and sitting of the varied and often contradictory statements by different authors, and an independent opinion that commands respect. Thus under Coca the author states that he believes there are only two sub-species or varieties, which he calls respectively novo-granatens and bolivianum. In following the U.S. Pharmacopoeia the new methods of nomenclature of course effect some alterations, thus Bachaemonadenron myrrha becomes Commiphora myrrha. The nomenclature, however, is less up to date under the Cryptogams, thus Agaricus muscarius now reappears under its more accurate designation, Anamita muscaria, whilst Agaricus atramentarius and A. ruber still remain under their old names, and white agaric does not, as it should (either directly or by cross reference) appear under the heading of Polyporus officinalis. It is therefore difficult in some instances for the uninstructed to know what is the correct scientific name of the plant referred to. These are, however, minor points which serve to show, in a work covering such an immense extent of ground, how many difficulties have to be overcome in face of the ever-increasing tide of human knowledge.

The popularity acquired by the 'National Dispensatory' on its publication fifteen years ago, as a work affording accuracy and complete information for the use of medical men and pharmacists, has been well maintained in subsequent editions by the revision of its contents, bringing it up to the level of the science and practice of the period. In the present edition the same plan has been followed, and although one of the chief editors died before its publication, his portion of the work had already been practically completed, with the assistance of Professor Caspari, of the Maryland College of Pharmacy. The therapeutic portion has been revised with equal thoroughness by Dr. Skill. The alterations and additions are more extensive than in any previous edition, owing to the great changes which have been made in the United States Pharmacopoeia, and considerable use has been made of information appearing in foreign pharmacopoeias. Synthetic remedies and unofficial preparations now in use have been fully described. Chemical and pharmaceutical processes, as well as the formulæ for galenical preparations, have been discussed, and the most approved apparatus and tests have been fully described. Formulæ are given both in ordinary weights and measures and in their metric equivalents; many tables and lists are inserted for convenient reference, together with a therapeutical index of diseases and remedies; and a very copious general index, including together some twenty-five thousand references, and every element of utility has been provided for rendering the work even more valuable to physicians and pharmacists than it has hitherto been.

The arrangement of the matter is in chapters, placed in alphabetical order, and the whole of it, whether relating to official or unofficial drugs and preparations is included in one section, extending over 1737 pages, while the tables and lists of reagents, and tests of drugs and preparations official in the United States and British Pharmacopoeias, are contained in an appendix.

WRIGHT'S IMPROVED PHYSICIANS', SURGON'S', AND CONSULTANTS' VISITING LIST, 1895. Compiled by Robert Simpson, L.R.C.P., L.R.C.S. Bristol: John Wright and Co. 5s. 6d.

The first edition of this list was described in the Journal for October 14, 1893, and the present one is very similar, except that, as the result of numerous suggestions, material improvements have been introduced. Thus, the paper has been slightly thickened; and there have been added two pockets, a cash column to each page, two cash leaves to each month, pages for vaccination engagements, a purse fastener, which will be found more readily handled than the old-fashioned tuck, and other minor additions. It is doubtful if a visiting list could be better arranged than this.

GRIFFIN'S CHEMICAL HANDICRAFT. Pp. 458. 2s. 6d. London: John J. Griffin & Sons, Ltd.

This is a new edition of the well-known illustrated and descriptive catalogue of chemical apparatus, the special feature of which is the detailed explanation given of special processes in which the apparatus is used, as well as of the construction of the apparatus itself. The needs of the modern chemist seem to be fully served, the most recent appliances being figured and described.
Notes and Queries.

**ROUGE DU JAPON.**

[783.] This preparation is a kind of lake, consisting of lead oxide, coloured with eosine. It is prepared by electrolyzing a 10 per cent. solution of sodium acetate with two lead electrodes. The eosine in solution is placed in the vessel in which electrolysis is proceeding, and is absorbed by the lead oxide as it is formed. The colour of the product can be varied by regulating the concentration of the eosine solution. By substituting rhodamine or other colouring agent for eosine, different colours can be obtained, and by using zinc instead of lead for the electrodes a preparation will result having zinc oxide as its basis. In like manner the sodium acetate may be replaced by sodium nitrate, or a mixture of that compound with ammonium nitrate (Bull. de pharm. de Bordeaux).

**THERMOMETERS FOR HIGH TEMPERATURES.**

[784.] To indicate temperatures above 250° C., thermometer tubes are filled with nitrogen under pressure, and temperatures up to 450° can then be recorded. M. Niehl, of Berlin, has also recommended the use of gaseous carbonic acid, by means of which he has recorded temperatures up to 550°. The tubes are made of Jena boro-silicate glass, which does not soften below 600° (Bull. de pharm. de Bordeaux).

**MISCIBLE EXTRACT OF COCA.**

[785.] "I should be pleased to be informed of the best method of preparing a miscible extract of coca to mix with a slightly acid liquid. — Peru."

**DETERMINATION OF MENTHOL.**

[786.] Heat peppermint oil, 20 Gm., with alcoholic normal sodium hydrate solution, 30 Cc., for an hour in a flask with a reflux condenser. Well wash the saponified oil with water, and boil for an hour in a flask with a condensing tube, with an equal quantity of acetic anhydride and sodium acetate, 2 Gm. Cool the product, well wash with water, and then with a dilute solution of sodium hydrate; dry in contact with calcium chloride, and filter. Now saponify 8 to 10 Gm. of the resulting oil as above, using 50 C.c. of alcoholic normal sodium hydrate solution, and determine the uncombined alkali by titration. Each 1 C.c. of normal alkali required for saponification corresponds to 0.156 Gm. menthol, or 0.198 Gm. methyl acetate. Therefore, to ascertain the percentage amount of menthol in the non-acetylated oil (free from ester), subtract from the quantity of oil used for saponification 0.042 (the difference between 0.156 Gm. and 0.198 Gm.) for each 1 C.c. of normal alkali consumed, and calculate the total percentage, P, of menthol by the following formula:

\[ P = \frac{a \times 15.6}{8 - (a \times 0.042)} \]

where S grammes of acetylated oil require for saponification a-cubic centimetres of normal alkali (Schimmel's Bericht).

---

**Novel Appliances, Apparatus, etc.**

**NEW MENTHOL INHALER.**

A convenient little inhaler for the mouth and nose has been introduced by Messrs. Godfrey & Cooke, Conduit Street, W., as a means of freely introducing the vapour of menthol into the respiratory tract, in hay fever, influenza, nasal catarrh, etc., and may be easily carried in the waistcoat pocket. It consists of a vulcanite tube, fitted with a solid rod of menthol. The narrow end of the tube is placed in the mouth or nostril, as the case may be—a loose soft rubber cap being used in the latter instance, as represented in the illustration—and air is then drawn through the length of the tube, becoming impregnated with menthol in its passage. By carrying the inhaler in the waistcoat pocket it is kept at a temperature approaching the heat of the body, and the menthol then volatilizes more readily.

**PATENT PERCOLATING CUP.**

This cup is made of china, and fitted with a kind of strainer under a mouth protection, thus forming an infusion pot and cup combined. The tea, senna, etc., is placed in the body of the cup, over which the saucer is made to fit compactly, forming a lid during the infusion, and the liquid is strained in the act of drinking, any sediment being retained in the cup. Various other obvious uses for the cup are suggested by the makers, Messrs. Page & Co., 52, Wharton Street, King's Cross Road, W.C.

**NEW "ECLIPSE" MICROSCOPE.**

The instrument illustrated is made by Messrs. Boss & Co., New Bond Street, W., and affords the greatest facilities for practical work, combined with stability and the necessary strength to withstand hard use. As shown in the illustration, it is mounted on a circular foot, the centre of gravity being so situated that equal steadiness is secured in every direction. The stage being firmly fixed to the strong upright pillar, is not liable to flexure, and the method of attachment of the limb carrying the sliding tube insures perfect steadiness of the optical combinations. The fine adjustment is very substantial, and being independent of set screws is not subject to derangement. Its fitting, by a new contrivance, is completely covered at all points, being thus preserved from disturbance or injury by dust. This microscope is furnished with two eye-pieces; 1" and 2" object glasses of highest excellence.
and large angular aperture, both adjusted to a double nose-piece, so that they focus in the same plane; swinging mirror and stage diaphragm, which is so arranged that they need not be removed should a tube-fitting be attached to admit the use of a condenser. The whole of the apparatus packs into a compact mahogany case.

Miscellaneous Novelties.

The use of aluminium is extending rapidly now that the price of the metal has been reduced, and Messrs. Maw, Son & Thompson, of Aldersgate Street, E.C., are making a special feature of its applications for pharmaceutical purposes. Thus, they are supplying sets of grain and drachm weights in aluminium, which possess manifest advantages over brass ones. Besides being comparatively unannishable, they are about double the size of the corresponding brass weights, and accordingly much more convenient to handle. They are also very plainly stamped, and cost but little more than the ordinary sets. Funnels, evaporating dishes, and decoction pans in aluminium are also supplied. The “Cradle” Bed Pan (Patent No. 2379), designed by an experienced hospital nurse for invalids, ensures comfort in use by supporting the body from the hips. The spinal column thus rests lightly in the curve without painful pressure. It can be used with or without a pad (which is made specially as an additional comfort) and also as a bed bath. Messrs. Maw, Son & Thompson are agents for this appliance as well as for an improved modification of the well-known French dropping bottles. The new form is made in various sizes, from live to one hundred grammes, and every size delivers uniform drops with a given liquid. Thus forty drops of water from a bottle of any size measure fifty minims, forty drops of rectified spirit equal twenty minims, and so on. The quick filtering funnel represented in the illustration should be found useful and more satisfactory than the older forms. It is made of glass, and the raised ridges inside are solid elongated wedges, so arranged as to support the paper and prevent it from coming in contact with the sides of the funnel.

Other novelties shown by this firm, which are worthy of attention, are a small spirit stove with a regulator for the flame, a collapsible carrier for six syphons or bottles, a handy French tincture press and a small French pill-pipping machine, suitable for small pharmacies, and an elegant new type of counter scale constructed on the plan of a chemical balance. It consists of a skeleton beam supported by a pillar fixed on a walnut stand. The movement is indicated by a pointer, and the beam and pans are supported when out of use, so as to save wear and tear of the bearings, being released by turning a screw in front of the stand. The scales weigh up to two pounds, and turn with a fraction of a grain.

New Filtering Cartridge.

Messrs. Schleicher and Schüll, of Duren, who are well known as manufacturers of filtering paper especially adapted for use in analytical operations, have introduced a very useful contrivance for containing material that is to be extracted with ether or other solvents in the Soxhlet apparatus. It consists of an elongated shell or cartridge of unsize paper, closed at one end and fitting into the Soxhlet apparatus. The material to be extracted is packed into the cartridge, which is arranged so that the condensing ether drops into it and percolates through the cartridge into the receptacle below. By this means perfectly clear ethereal extracts can be obtained with facility, and the cartridge can be used a great number of times for the same purpose.

Obituary.

Notice has been received of the death of the following:—

On November 14, Walter Smyth, Pharmaceutical Chemist, Merthyr Tydfil. (Aged 69.) Mr. Smyth was a Justice of the Peace. He was local secretary for the Merthyr District, and had been a member of the Pharmaceutical Society since 1855.

On November 14, Francis Joseph Allen, Chemist and Druggist, Plymouth. (Aged 27.) Mr. Allen was an Associate of the Pharmaceutical Society, and formerly of the Apothecaries' Hall, London.

On November 15, H. J. Manfull, Chemist and Druggist, Nottingham. (Aged 48.)

On November 17, Henry Stevens Jones, Pharmaceutical Chemist, Fulham. (Aged 74.) Mr. Jones' membership with the Society dated from 1849.

On October 12, Allan Hick, Pharmaceutical Chemist, Wath. (Aged 71.) Mr. Hick had been a member of the Pharmaceutical Society since 1849.

On October 29, Richard Winter, Chemist and Druggist, South Shields. (Aged 73.)
Correspondence.

MEDICAL MEN AND MANUFACTURERS.

Sir,—Will you permit me to use the medium of your Journal to make a protest against an amount of literature to be an anachronism with me. I am asked to be an instrument in the treatment of cases committed to my care? Scarcely a day passes without my receiving from the one or the other of those enterprising gentlemen some very positive statement that a particular form of disease can be appropriately combated only by a certain remedy manufactured by themselves; and not infrequently they are good enough to send me the flimsy nostrum itself, which I am asked either to try upon myself or make about with me and try upon somebody else. I could not be expected to contract a gonorrhoea or a typhoid fever in order to test the efficacy of the vaunted remedies; nor would it be honest on my part to make corpora viva of my patients upon the speculae of some manufacturer. I do not venture to deny his competency of forming an opinion upon a matter upon which he is, in the nature of things, profoundly ignorant. Meanwhile, I may, perhaps, be permitted to point out to that very objectionable fraternity that, first of all, I treat patients and not diseases; that, secondly, I prefer a remedy carefully adapted to the circumstances of each case to the ready-made which is supposed to fit everybody; that I am quite capable, without extraneous help, to write down, if I wanted such a thing, a Mistrur Tusci, which, I presume, is intended as the Latin for a cough mixture; that I see no reason why the word should not be allowed the additional expense which the large outlay for advertisements entail upon this article; and, lastly, that I have the firm conviction that there may be found some properly qualified pharmaceutical chemist who would be able to dispense my prescription and supply the drugs of as good a quality as they can be had of the advertiser.

I. G. NOTUS, M.D.

TINCT. MYRTI, B.P.

Sir,—I have been struck with an observation made by Mr. Jones in his paper on tinctures and tincture-making, as reported in the Journal, p. 496. How certain myrrh was an example of tincture which could not be prepared by percolation without previous maceration. So far as I have observed, the myrrh is completely exhausted by percolation alone. I have usually made thirty ounces of the tincture at a time in this manner, following it up by water displacement. The water generally disperses about half an ounce of the tincture, and then the viscid mixture formed by the Arabian reference to the more water added. The process stops, says Christison, in his Dispensatory, remarks regarding the tincture of the Edinburgh Pharmacopoeia: "The tincture is best made by percolation. Most of the active principles pass through at the beginning with a little alcohol, forming a thick, viscid, oleo-resinous fluid; and when the spirit directed by the Pharmacopoeia has been transmitted, gum alone is left." Perhaps Mr. Jones would kindly give some particulars in regard to the imperfect exhaustion by percolation alone.

Glasgow, N.B.

A. McKELLAR.

Answers to Correspondents, etc.

"A Phosphate Salt."—You fail to authenticate your communication by enclosing your name and address. Read what is published on subject you refer to, on pp. 464-5.

"Micros."—You can procure well-made microscopes and accessories, suitable for your purpose, from numerous good-class firms. Refer to our notices of novel appliances, etc., and advertisement columns.

"Inquiring."—According to Die Natur, "cryocaeae" consists of equal parts of phalen, camphor, and saponin, together with a slightly smaller quantity of oil of turpentine. The mixture is described as solidifying with heat and liquefying again when slowly cold.

"Student."—You can procure a copy of 'Advice to Students,' containing the articles referred to, by sending a stamped and addressed wrapper to the Registrar, 17, Bloomsbury Square, W.C.

John Austin.—Methyl blue appears to permanently stain the cellophane plates only, and sections so stained can be preserved indefinitely if mounted in glycerin and kept in the dark. A special medium that answers remarkably well for preserving vegetable colours, etc., where most others fail, is prepared by Mr. E. H. Farr, Uckfield, Sussex, who might possibly supply you with some.

Books, etc., received.

Diary of the Week.

SATURDAY, DECEMBER 1.
Pharmaceutical Football Club v. St. Michael's, at Wormholt Farm, Shepherd's Bush, at 3 p.m.

MONDAY, DECEMBER 3.
Society of Chemical Industry (London Section), at 8 p.m.
"Specimens of India-rubber, and Petroleum Oil, Varnish and Soap," will be exhibited by Thomas Christley.

ROYAL INSTITUTION, at 5 p.m.
General Monthly Meeting.

TUESDAY, DECEMBER 4.
Pharmaceutical Society of Great Britain, Benevolent Fund Committee.
Finance Committee.
General Purposes Committee.

WEDNESDAY, DECEMBER 5.
Pharmaceutical Society of Great Britain, at 11 a.m.
Meeting of the Council.
Society of Arts, at 8 p.m.
T. C. de Marais Testimonial Presentation by Mr. E. N. Buttt, at 16, Bloomsbury Square, at 6 p.m.

THURSDAY, DECEMBER 6.
Chemical Society, at 5 p.m.
Ballot for the Election of Fellows.
"Latent Heats of Fusion," by Holland Crompton.
Linnean Society of London, at 5 p.m.
Chemists' Assistants' Association, at 8.30 p.m.
Discussion: "Can we stop 'Company' Pharmacy?"

ON THE INFLUENCE OF ALCOHOL ON CHLORAL HYDRATE.*

BY E. SCHAR.

In studying the action of chloral hydrate upon living substance, I made use of various aqueous and alcoholic solutions of this compound, and observed a rather curious behaviour of the substance with alcohol. This behaviour, being then quite new to me, although perhaps already noticed by others, and not having been till now described in detail, a brief description of it may perhaps be of interest.

It is well known that the official chloral hydrate, resulting from anhydrous chloral or trichloraldehyde (CCl₃-CHO) by contact with water, has been considered either as a "molecular compound" of chloral with one mol. of water, that is to say, as \( \text{CCl}_3-\text{CHO} + \text{H}_2\text{O}, \) or as a closed compound, viz., as the glycol of trichlorethylidene \( \text{[CO}_1-	ext{CH(OH)}_2\text{].} \)

It would not be convenient on this occasion to mention the reasons for these opinions, and it will be sufficient to say that the idea of chloral hydrate being a molecular compound seems to be supported by the fact that, when heated to the boiling point, is dissociated to that degree that the vapour, as shown by the determinations of its density, consists as to one half of molecules of anhydrous chloral and as to the other of molecules of water.

The same difference of theoretic consideration comes out also for the closely allied chloral alcohols

\[ \text{CCl}_3-\text{CHO} + \text{C}_4\text{H}_9\text{OH}, \text{or} \text{CCl}_3-\text{OH.OC}_4\text{H}_9\text{.] \]

which plays an important part as an intermediate product in the preparation of chloral, and has been mentioned in all newer pharmacopoeias on account of being confounded with the hydrate. This compound (alcoholate), as regards dissociation by heat, behaves in the manner already noticed for chloral hydrate.

There is no doubt as to the solubility of chloral hydrate in water and in alcohol, and chemical handbooks and pharmacopoeias generally state that it is readily soluble in both liquids (1 part of water at 0°C. dissolves two parts at 15°C., about four parts of the hydrate). On the other hand, there are various discrepancies as to the solubility of chloral alcoholate in water. All the statements are based upon the supposition that it is to a certain degree soluble. In one place the "slow but easy" solution of the alcoholate in water is noticed, in another we are reminded of the difficult solubility in cold water," while F. A. Flückiger (Pharm. Chem., 1888, ii. 93) more precisely describes the behaviour in presence of water in the following terms: "The alcoholate is deliquescent and less soluble in water than the hydrate, so that, after solution of the same quantity of water by which it forms oily drops, which are only dissolved by addition of more water, while in case of the hydrate the solution takes place almost instantaneously."

An alcoholic solution of chloral alcoholate behaves in a similar manner with water. When, for instance, a 20 per cent. solution of the alcoholate is mixed with a quantity of water corresponding to the twenty-fold or thirty-fold weight of the substance dissolved, there is the same instantaneous separation of oily drops sinking to the bottom rather quickly to form a heavy layer of oily appearance. This layer, during a certain lapse of time, when stirred with a glass rod may again and again be divided in numberless insoluble drops, and they dissolve in the water only when kept suspended in the liquid for a long time, when the ole layer is left to stand under water for one or more hours. When the stratum is then stirred, it dissolves immediately, just as if a layer of melted chloral hydrate had been stirred under water.

This behaviour leaves no doubt as to the fact that chloral alcoholate, as such, is not soluble in water, or only in a very limited degree, and that the progressive solution is the result of a chemical or physical action, the alcoholate being converted into hydrate. But as there is a limit to the extent that diluted alcohol will still dissolve the alcoholate as such, as well as absolute alcohol, it is evident that in the above described experiment the alteration of the alcoholate by contact with water will be more striking and more perfect the smaller the quantity of spirit used for the solution of the alcoholate.

These observations consequently lead to the behaviour of chloral hydrate in alcoholic solution. When a solution of the hydrate in alcohol (in the proportion of 20 to 25 per cent.) is freshly prepared it behaves as at first and during a certain time as a solution of chloral hydrate, giving a clear mixture when poured into five to ten times its volume of water.

But according to the strength of the alcohol and the prevailing temperature such a solution changes after a time, and assumes more and more the character of an alcoholic solution of chloral alcoholate, becoming more or less turbid on addition of water and depositing oily drops. At last it behaves almost like a solution of chloral alcoholate in spirit of wine. We have therefore in this case evidence of a change proposed to that which seems to take place when the alcoholate is brought into contact with water. The chloral hydrate may continue to exist for a time as hydrate in alcoholic solution, but it is gradually changed into the insoluble or sparingly soluble alcoholate, the water contained in the molecule being replaced by ethylic alcohol. It may be mentioned incidentally that the oily layer formed on pouring into water an old alcoholic solution of hydrate behaves in the manner already noticed, that is to say, although apparently undisturbed, it turns into a liquid, readily soluble in water on stirring.

This formation of alcoholate from hydrate was noticed by F. A. Flückiger (loc. cit. 93), in mixing rather concentrated solutions of chloral hydrate with alcohol. The production of alcoholate, separating as an oily substance of sparing solubility, may be observed by adding to the said mixture some salt soluble in water and in alcohol, as for instance chlorides of calcium or iodide of potassium. In fact, by diluting aqueous solutions of chloral hydrate (containing 20 to 50 per cent.) with alcohol, and adding concentrated aqueous solutions of the salts mentioned, we can obtain the separation of oily drops behaving exactly in the manner already described. In these experiments the powerful attraction of these haloid salts for water promotes the separation of water from the hydrate.

---

VOL. LIV. (Third Series, Vol. XXV.), No. 1276.
and the chemical addition of alcohol, viz., the formation of alcoholicate.

As regards the theoretic conclusions which might be drawn from these experiences respecting the particular labile condition of chloral hydrate, it must be granted that, owing to the present view of physical chemistry in regard to the condition of chemical compounds in solution, the relative facility of change of the hydrate into the alcoholicate and vice versa, cannot a priori be interpreted in favour of the opinion that these substances are "molecular compounds."

It is my intention to investigate the special conditions of this change in an alcoholic solution of the hydrate, which sometimes happens within the first hour, and goes on much more quickly at a higher than at a lower temperature.

THE NERVOUS SYSTEM IN THE VEGETABLE WORLD.*

BY J. REYNOLDS GREEN, M.A., B.C.D.,
Professor of Botany to the Pharmaceutical Society of Great Britain, and Dean of the School of Pharmacy.

(Concluded from page 416.)

Now, passing to the subterranean part of the plant, let us consider the behaviour of a root in penetrating the soil. It penetrates gradually by virtue of certain rotatory movements, which it is continually carrying out, making its way between the crevices which exist in the soil. It has a downward course, because it is permanently acted upon by a particular force which I have alluded to already, the force of gravitation. This has such influence on the roots, in some mysterious manner, that they always grow downwards. In going through the particles of soil one can see that the root is not at all unlikely to come in contact with impracticable barriers. It will grow, perhaps, against a stone, and then its growth apparently should be stopped. Now it is found that when the root comes in contact with an obstacle of this kind, the stimulus of contact brings about a curvature in the root of such a character that it grows over the obstacle, passes round it, and resumes its downward course when it has got beyond it. This experiment can be readily carried out. You can, by attaching to the growing part of a root, preferably by attaching to it some small body, a piece of card or something of that sort, persuade it that it is in contact with an obstacle that it must avoid, and it will perform a curvature in a perfectly normal way. Mr. Darwin has put on record some very curious experiments on this point.

We will consider next the behaviour of the tentacles of Drosera, which bend over when a part of the surface of the leaf is touched. There seems to be a direct understanding on the part of the outside tentacles as to whereabouts the disturbance is coming from. That is a very important point when we consider the sensitiveness of the plant. It is not a mere aimless movement. The tentacles curve over towards the exact point where the fly has settled. We get a very definite movement in direction then. These tentacles are formed of a number of delicate cells, which are arranged in a row, and they are full of living substance with a coloured cell sap. When this irritation is brought about certain changes take place in these cells. Darwin called the phenomenon one of aggregation, the aggregation of protoplasma into these various shapes. The term we may still use in that way, although it does not convey any very great amount of definite meaning. The aggregation of protoplasma, then, attains the substance. The action of the stimulus also produces excretion of a curious character from the ends of the tentacles, the cell walls of the gland.

In connection with this process we must note the extreme sensitiveness which these organs show, as well as their appreciation of locality. Mr. Darwin tried various methods of stimulating them, and among others that of laying upon the glands certain small portions of human hair. He found that a little portion of hair weighing, I think, of a grain, laid on the central glands of these leaves, was an insufficient stimulus to cause an induction of these tentacles in a comparatively short time. He attempted to compare the difference in power of appreciating sensation between the human tongue and the glands of Drosa, and found that his own tongue was not capable of perceiving this amount of weight or contact which was capable of stirring up Drosa glands in this way. Indeed, I think he comes to the conclusion that it is two and a half times as sensitive to touch as the human tongue. Another plant, which behaves in a somewhat similar way to Drosa, but is not quite so sensitive, is the Pinguicula, or Butterwort. When a little fly alights on the leaf, which occurs frequently, the leaf curls over in response to the stimulus and encloses the ant or little fly just in the same way as the tentacles of the Drosa. It is not so sensitive, but still it works.

You all know that various plants have a climbing habit. They have very weak stems, and they cannot get along by themselves; they must lift themselves up, as it were, into proper relations to the air by catching hold of something and climbing by means of it; some do so by tendrils laying kind of a support. These tendrils are again sense organs that are extremely sensitive, and, as before, the sensitive part and moving part are not identical. They are always sweeping around slowly in the air in circles, and if they come in contact with anything they respond by a peculiar movement, a contraction of their substance, which leads to a twining round of the substances. Now it has been found that the sensitive part of the tendril has a power of appreciating foreign objects which may be compared to the sensitiveness which Drosa itself has shown. Similarly, we find that in the root the sensitiveness to moisture, which is a kind of touch, is equally great. It is by virtue of this that the root is enabled to grow through fairly arid soil; if there is any moisture anywhere the root will find it. In some subtle way its presence seems to be made manifest to it, and a curvature takes place in that direction.

The Senses of Taste and Smell in Plants.

Plants have also a sort of power of appreciating flavour, having, as it were, a rudimentary taste. Let us go back for a moment to this sun dew. Drosa can be stimulated not only by contact but by allowing it to taste various materials. Various liquids if placed on the leaves, if appreciated by the plant, inevitably result in a movement of the tentacles. It naturally occurs to us to suppose that it tastes

* Lecture delivered at an Evening Meeting held on Wednesday, November 14.
the fly which it is about to eat. This has been tested, and it has been found capable of appreciating certain substances, and not being the least affected by certain other ones. It does not care for water, it does not care for solution of gum, and it has an utter disregard to the charms of sugar, neither does it care for starch or alcohol. It has an equally apathetic attitude towards olive oil and tea. On the other hand, if you give it a little infusion of milk it will curl up very quickly. It also likes milk, it can do with white of egg, anything indeed which seems to be of a meaty character seems most powerless to appeal to the rudimentary taste which Drosena has.

Another substance for which Drosena has a devoted attachment is ammonium carbonate. Any of these if submitted to it will inevitably cause an inflexion of the tentacles. There is another plant of a somewhat similar character, the Dionaea, or Venus's fly-trap. It is a flat leaf which lies open, and has a sort of fringe at the edges, something like your fingers, so that if it is stimulated it closes and shuts its fingers over the object which unfortunately has given it a stimulus. You can see that this, of course, would lend itself to the capture of flies, and is known as the Venus's fly-trap on that account. If this plant be tested in the same way it is also found to have rudimentary but a perfectly keen power of taste; it does not like waters nor sugar solutions, but it does like nitrogenous material such as extract of meat and similar bodies.

Taste and smell in our own case are not very far apart, indeed, a condition of the sensation which we know as taste very frequently has the power of smell added up with it, considerably. Now certain plants show behaviour which suggests the sense of smell. The antherozoids or male cells of ferns and other cryptogams, when set free from the place of their formation, make their way to the archegonia which contain the ova and pass down the neck of this receptacle to fuse with the ova. The problem is, How do they find their way to these archegonia? How is it they do not go aimlessly floating about, swimming all over the place just off the prothallium, and never come near the archegonia at all? This is due to rudimentary power of smell. It has been found that these archegonia excrete peculiar substances, which to our senses are not odorous, and it is found that when these substances are excreted from the archegonia they are appreciated by the little free swimming organisms that are floating about in the neighbourhood, and they make for them; they find the place where this odiferous substance, if I may so call it, is being put out, and they are thereby guided to the particular necks of the archegonia. Various bodies show an appreciation of odorous substances in this way. Professor Pfeffer, perhaps the first observer to deal with this, has ascertained what it is which is excreted from the archegonia of the fern which attracts the antherozoids, and he found it is malic acid. They excrete malic acid, and it is appreciated apparently at a distance by these little bodies; to the malic acid they go, and are thereby directed to the archegonia. Other plants like different substances; some like sugar, some other bodies, and so on, but there seems to be a sort of selective power which the different antherozoids possess. Saprolegnia, a fungus which lives on dead flies, likes extract of meat, and is attracted by it. Asthalium is very fond of extract of tansy, not a particularly attractive substance in the abstract, but still Asthalium likes it, and is repelled by other bodies. Now, although certain substances attract them in this way, there is no inevitability about the attraction; there is a distinct power of selection; for instance, malic acid in the strength of \( \text{mg} \) is very attractive to the antherozoids of the fern, but if you neutralise it with soda so as to make a sodium salt of it it would not care a bit for it. There is, therefore, a power of apparently appreciating fragrance which is undetected by our own senses. Whether this is to be regarded as small or whether it is taste is perhaps discussable. It may be that it is taste, but that involves, of course, no power of response until the thing is actually in contact, whilst odour can act at a distance, and it seems quite possible that the antherozoids may be drawn from a distance to the archegonia. There is very little excretion, of course, put out from any one archegonium, and it seems as if the response were too quick and too readily brought about for it to be taste.

The Muscular Sense in Plants.

Now we are possessed ourselves of another peculiar sense. We have the power of appreciating weight, an appreciation of external force; that is, we are acted upon by gravity, and we have the power of appreciating difference in the weights which we draw up against gravity. I want you to see that plants also have this peculiar muscular sense just as we have, only in a much finer way. The action of this external force which we know as gravity is very small, or whether it is perhaps discussable. It may be that it is taste, but that involves, of course, no power of response until the thing is actually in contact, whilst odour can act at a distance, and it seems quite possible that the antherozoids may be drawn from a distance to the archegonia. There is very little excretion, of course, put out from any one archegonium, and it seems as if the response were too quick and too readily brought about for it to be taste.

The Muscular Sense in Plants.

Now we are possessed ourselves of another peculiar sense. We have the power of appreciating weight, an appreciation of external force; that is, we are acted upon by gravity, and we have the power of appreciating difference in the weights which we draw up against gravity. I want you to see that plants also have this peculiar muscular sense just as we have, only in a much finer way. The action of this external force which we know as gravity is very small, or whether it is perhaps discussable.
and got fixed inside. He found when he tried experiments of reversing the direction, the root behaved as if there were nothing of it sensitive except the tip. If the tip were turned vertically downwards, no curvature took place in the other part, whether it were upside, downside, or how it was, but if the tip was put so that it was bent sideways, the curvature took place exactly as if it were done if normally grown. We cannot have a better proof that the tip has, as far as gravitation goes, distinctly a sense of direction.

A great many experiments have been made to show that the root really has the power of appreciating forces acting along it in the direction of its axis, or, if you like, a rudimentary muscular sense, and I should like before finishing just to show you the plan which has been adopted to see how the root behaves if the influence of gravity is eliminated. An instrument used for this purpose is known as the "kleinmostat." It consists of a box in which the plant is placed in a pot or case. This is driven by clockwork in such a way that a slow rotation is brought about. The whole thing turns on its axis once in 20 minutes, so that each part of the plant is subjected to a downward pull for a definite, but short period, and then immediately the pull changes in its direction and ultimately becomes reversed, so that practically, every portion in demarcation being subjected to the influence of gravity, gravity has no effect on the whole thing. In that case it is found the root does not grow in a normal way, that it takes up a definite rotation to the position in which it is in the pot. It grows out at right angles to the substratum, whatever the direction of the substratum is. That instrument acts by eliminating the action of gravity altogether by making it play on all parts of the plant in succession. Another method was used by an older botanist nearly a century ago, an English botanist named Knight, who substituted for gravity a force which would make much greater, viz., centrifugal force. He grew plants on a wheel that he could make rotate either on a vertical or horizontal axis. When he rotated it on a vertical axis, swinging round with great rapidity, an effect was produced on the attitude of the plant. In the case of a young bean grown upon it, the plant does not grow exactly in the direction of gravity would indicate, but in a slanting direction. The shoots slant inwards towards the centre, the root always growing in the direction of the force and the stem against it. There is a sort of resultant position, gravity pulling it down and rotation sending it out, and it adopts an intermediate position between them, growing at an angle of 45 degrees. When the plant was grown on a horizontal axis, so that it rotated vertically, there was no effect of gravitation whatever, and the plant grew in obedience to what is known as centrifugal force, the stem growing inwards towards the centre, the root outwards in the direction of the force. Centrifugal force is that force which causes a string to be tight when you tie a stone to it and whirl it round your head; there is a considerable force on the string, varying with the weight and other conditions. Eliminating gravity in this way, it was found that the root responded to the new force, that it appreciated the new force and utterly neglected the old one.

Conclusion.

In conclusion, let us consider what the bearing of these facts is on the question of "Have plants a nervous system or not?" We have considered instances of both effarent or motor and afferent or sensory mechanisms. We have seen that stimuli received at one place have been expressed in movements or secretions brought about in another place. We must have seen, therefore, the idea in the plant: somewhere there has been the transmission of that molecular disturbance which in the higher animals we call a nervous impulse. There has been the transmission of the irritation, and the production of the movement at a distance, and a movement, moreover, which frequently is out of all proportion to the actual stimulus. A very minute bit of hair put on a Drosera could not be expected by its own power to move a single tentacle, yet the whole tentacles of Drosera have become detached. Now a study of the internal structure of plants shows us how in some way it is possible for this stimulus to be conducted. In the case of two cells taken from a part of one of the seeds of one of the palms, the living substance was made to shrink away from the limiting cell walls. It did not shrink away uniformly, but remained in contact at particular places, and at these places a very high power showed a sort of lozenge-shaped enlargement, which was apparently the connecting link between the living substance on the two sides of the cell wall. Now, of course, the question is, what is there in that little lozenge? It was crossed by a large number of very fine streaks which penetrated through the substance of the cell wall. A thick line across the centre is supposed to be an enlargement of a particular single line, and to indicate the thickness of the cell wall. Through small apertures in the cell wall the structure of living substance from one cell communicates with the living substance of the next. We have, therefore, here a rudimentary nerve fibre, a something which will enable the molecular changes to pass from cell to cell and so to travel out. You see then we have something which may be called sense organs; we have something which may be called something like nerve fibre. Have we anything which can represent a central mechanism that is in our own case the brain and spinal cord? Well, we have nothing ascertained, nothing differentiated; you may call the root tip, as Darwin did, if you like, a rudimentary brain, on account of its power of perceiving these impulses and responding to them. It is rather a differentiated sense organ, something that corresponds to the papillae of our fingers, or some sense organs we find in other parts of the sensory cells. The same may be said of the little tip of the canary grass. But still, although we cannot find anything structural, I think we cannot help being logically driven to the conclusion that there is a power in the living substance of the plant of acting as the central mechanism, although it is not differentiated. We are familiar in our animal experiments with a peculiar process known to physiologists as reflex action. It means simply this: that in the absence of consciousness a stimulus applied to a sensory surface is conducted to a central nerve cell and change is set up there, leading to the manifestation of a particular movement, so that you can always call that power of movement out by applying the proper stimulus to the par-
ticular sensory surface. This is very highly developed in the animal world, particularly in the Mammalia. Now in the plant we have something which in a way would cause this. Darwin in his book puts it down fundamentally as an instance of reflex action. It is the nearest thing that illustrates the point in the vegetable world.

You remember I told you that when the gland of *Drosera* was stimulated the protoplasm of the cells of the stalk underwent that curious churning movement which Darwin called aggregation. Now the reflex movement which he found to be possible was something like this: a gland in the centre was stimulated, the stimulus at once set up aggregation in the protoplasm in the cells of that particular tentacle, and the disturbance spread across the leaf, and on to the external tentacles, and there the protoplasm in turn was found to undergo aggregation. But the aggregation set in in these tentacles in the direction from the gland, and not from the point stimulated, that is to say, the impulse passed down the tentacle stimulated, across the leaf, and up the other tentacles to their glands, and then the latter set up aggregation in the cells below them, the change proceeding thus in the opposite direction to the stimulus. In that way the gland acted like the central cell in the spinal marrow of the animal body. This only approach to a differentiated central nervous mechanism at present known. The correlation of stimulus and movement which I have described, however, points to the presence of such a mechanism, although undifferentiated.

A careful study of the manifestations of plant life in these varying conditions leads us thus strongly to the idea of the essential unity of living substance in Nature. The discovery of protoplasm in the vegetable has led to investigations into its nature and its behavior, and more and more certainly we reach the conclusion that there is no difference in the innate substance; there is a great deal of difference in the differentiation which must be looked at in connection with the environment, but one throws light upon the other.

OPENING OF THE SOCIETY'S NEW PREMISES IN EDINBURGH.

DINNER OF SCOTTISH PHARMACISTS.

On the evening of Thursday, November 29, a dinner of Scottish pharmacists was held on the occasion of the opening of the Pharmaceutical Society's new hall and laboratories in York Place, Edinburgh, in the saloon of the Royal Hotel. The gathering was a large and representative one, there being upwards of 180 gentlemen present. Mr. J. Laidlaw Ewing, chairman of the North British Branch, occupied the chair, and the vice-chairmen were Mr. Charles Kerr, Dundee; vice-chairman for the North British Branch, and Mr. Robert MacAdam, Glasgow.

On the right of the chairman were Sir James A. Russell; Professor Alex. R. Simpson, Vice-President of the Royal College of Physicians; Mr. N. H. Martin, Newcastle, President of the British Pharmaceutical Conference; Rev. Dr. Allison; Rev. D. Morrison; Professor Sir T. Grainger Stewart; Professor T. R. Fraser; Professor J. Gibson; Dr. Littlejohn; Dr. Murdoch Brown; Dr. Stockman; Dr. William Taylor, President Scottish Society of Arts; Dr. C. Kennedy; Mr. Hippolyte J. Bianco, A.K.A., architect; Dr. Dewar, Dr. Proudfoot, Mr. W. Fraser, W.S.; Mr. J. S. Gellatly, S.S.C.; Mr. T. McNaught, S.S.C.; Messrs. Martin, London, J. Johnston, President Aberdeen and North of Scotland Society of Chemists and Druggists, Aberdeen, and J. Rymer Young, Warrington, members of Council; Mr. J. E. Stephenson; Dr. W. Ingles Clark; Mr. F. Boa, President Edinburgh District Chemists' Trade Association; Mr. T. B. Leith, Vice-President Edinburgh District Chemists' Trade Association; Mr. Alex. Kininmont, Local Secretary, Glasgow; Mr. J. Foster, Vice-President Glasgow and West of Scotland Pharmaceutical Society, Glasgow, Mr. Edward Evans, Liverpool; Mr. A. Gibson, Mr. S. M. Fraser, Glasgow; Mr. J. R. Eden, Mr. W. S. Stockman, Edinburgh; Mr. J. Heron, Mr. D. Murdoch, local secretary, Falkirk; Mr. A. Davidson, local secretary, Montrose; Mr. Wm. Dow, local secretary, Kinross; Mr. J. Forrester, divisional secretary, Central Edinburgh; Mr. H. B. Esard, L.D.S.; Mr. J. Wood, L.D.S.; Mr. J. I. Fraser, Mr. Innes, Mr. R. E. Baber, J. Stuchlisky, Mr. R. Pottage; also Messrs. R. J. Hendry, D. Macarren, A. Dobson, G. Coull, B.Sc., W. Danna, D. MacKenzie, J. Robertson, J. Currie, Glasgow; J. Davies, W. Howes, Wm. Barley, W. Smith, W. S. Glass, A. S. Birnie, and P. L. Dewar. On the left of the chairman were Mr. Carteigh, President of the Pharmaceutical Society; Professor A. Crum Brown, Mr. R. Hampson, Treasurer of the Pharmaceutical Society; Dr. P. A. Young, Treasurer of the Royal College of Physicians; Mr. Walter Hills, London, and Mr. D. Sorror, Kirkcaldy, members of Council; Mr. Bowman Macleod, President Scottish Branch, Odontological Society of Great Britain; Mr. R. Brendrige, Secretary of the Pharmaceutical Society; Professor P. Geddes, Dr. Stevenson Macadam, Dr. Church, Dr. Wm. Craig, Dr. A. Balfour, Portobello; Dr. Whitehall, Fort-Tullibody; Dr. Hugh Marshall, Mr. J. Neibit, Chairman Scotch Board of Examiners, Portobello; Mr. J. Macmillan, Glasgow, Vice-President Glasgow and West of Scotland Pharmaceutical Association; Mr. R. R. Simpson, W.S.; Mr. P. Morison, S.S.C., law agent to the Pharmaceutical Society in Scotland; Mr. A. Garvie, local secretary, Leith; Mr. T. Maben, local secretary, Hawick; Mr. W. Allan, local secretary, Dumfries; Mr. G. L. McGilp, divisional secretary, West Edinburgh; Mr. C. F. Henry, divisional secretary, East Edinburgh; Mr. J. Jack, Arbroath; Mr. J. H. Hardie, Dundee; Mr. D. B. Dott, Mr. A. Noble, Mr. Fisher, Dumferrline; Mr. J. Rutherford Hills, assistant secretary to the Pharmaceutical Society; Mr. R. Dick, Mr. G. H. Laird, Mr. W. Greig, Inverness; Mr. R. E. Denken, Dr. W. Day, Professor Drena Kunz, Mr. T. Symington, Mr. W. Mackay, Mr. A. Kennedy, Mr. D. Mackenzie; also Messrs. W. M. Manson, J. Lothian, W. Allan, Kirkcaldy; J. Scater, C. Arthur, J. R. Young, Jun., W. T. Law, Partick; W. Taylor, Somerville Shaw, W. Anderson, W. Cunningham, D. Mitchell, Haddington; Mr. J. Laidlaw Ewing, President; Mr. Henry Atkinson, W. P. Wilson, Dunbar; R. Stenhouse, Musselburgh; D. Rainy Brown, James Neibit, Portobello; and G. Melvin.

Apologies for absence were intimated from the Right Hon. the Lord Provost of Edinburgh, the Right Hon. the Solicitor-General for Scotland, Professor Gairdner, President of the Royal College of Physicians; Dr. P. H. Macalren, President of the Royal College of Surgeons; Professor Sir Douglas Macalren, Dr. Bruce Goff, President of the Faculty of Physicians and Surgeons, Glasgow; Dr. Clouston, President Medico-Chirurgical Society of Edinburgh; Mr. R. J. Neibit, President Shetland, Dr. William Neibit, President Shrewsbury, Vice-President of the Pharmaceutical Society; Professor Bayley Balfour; Professor Caeb, Aberdeen; Dr. Clegorn, Strathclyde; Messrs. Abraham, Allen, Atkina, Bottle, Gosling, Green, Grose, Harrison, Newholm, Richardson, Schacht, and Soutiall, members of Council; Professors Atfield, Dunstan,
The Chairman gave "The Queen and Royal Family." He said pharmacists were all loyal subjects of Her Majesty, deeply attached to her person and throne. They had lately again the Prince and Princess of Wales sharing in the sorrows and joys of the imperial house of Russia. He was glad to think that sympathy would not be thrown away, but that it would lead to a better and more cordial understanding between that great country and our own. He thought it was not out of place to express the hope that the young kinman of the Prince of Wales and his wife might have a long and happy life, and that he would follow in the footsteps of his lamented father in securing for that great empire and Europe the inevitable blessings of peace. The Chairman next gave "The Navy, Army, and Reserve Forces," coupled with the name of Lieut.-Col. Storrar.

Lieut.-Col. Storrar, in replying, said that for him to recommend for the Navy and Army was something like a registered apprentice replying for the Pharmaceutical Society. But even a registered apprentice knew something more about the Society than an outsider, and it was not too much to say that possibly a volunteer knew more about the Navy or the Army than a civilian. The Chairman for the Corporation, which he had spoken of those branches of the service, he claimed for the volunteers that they had been a great benefit to the Army as well as to the country. As a nation they had been rather inclined to look down on their soldiers and sailors, but the volunteers had popularised and familiarised the nation with the Army. He had been a volunteer for a long number of years, and he had never regretted being so; it was the only chance he had of getting good healthy out-door exercise. He intended to continue a volunteer until disqualified by age.

The Chairman then proposed "The Lord Provost, Magistrates, and Town Council of Edinburgh." He said it was a characteristic of the great municipal corporations that they were especially subject to their heavy duties and responsibilities. He did not suppose that in the long history of the city of Edinburgh there had been a time when the work devolving upon their corporation had been greater than at the present time. He would not detain them by enumerating the various schemes to which the corporation was committed, but in such a company as that he might refer to the influence for good which the corporation had exercised on the public health of the community. The old city of Edinburgh was a very picturesque and very crowded one, but it was also a very insanitary one—indeed a hotbed of disease. That was all changed. They were greatly indebted for that to the beneficent scheme with which the name of Lord Provost Chambers was associated. In the second place it was due to Sir James Russell as convener of public health, and to the vigour and ability of the veteran officer of health, Dr. Littlejohn, whom they had there. It would not be right were he to say that the health of Edinburgh was what it ought to be. So long as a certain building, he would not say adorned a slope of the Queen's Park, so long would they say that the health of the city was not in a satisfactory condition. But when the improvement of the city, which Lord Provost Russell had begun, was completed the new water supply had been brought in, and the new Fever Hospital had been erected and smallpox had disappeared altogether, they would enter upon such a period of good health that physicians and pharmacists alike would look forward to it with some searching of heart. He coupled with the toast the name of Sir James Russell, an old friend of their Society. During his tenure of the Lord Provostship he received the British Pharmaceutical Conference at their meeting in Edinburgh two years ago with great courtesy, and for that they were deeply indebted to him. They would agree with him when he said that Sir James discharged the duties of the high office of chief magistrate of the city with dignity, with unwearied diligence, to the advantage of the citizens, and with great credit to himself.

Sir James A. Russell, in replying, said the Chairman referred to the changes taking place in connection with municipal government, but some of those changes were not new as regarded the city of Edinburgh. He did not know any department of human life which was foreign to the government of Edinburgh in olden times. Perhaps the one circumstance in which the corporation of the city differed from that of other corporations throughout the country was its relation to education, because it had the charge of a university. That institution had been intimately connected with that university, and had therefore had pressed upon them the necessity of attending to educational interests. The corporation of the city had also had an intimate connection with all branches of the medical profession. He did not know any city throughout the world where the cultivation of medicine in all its departments occupies such a high and honourable position as it did in the city of Edinburgh, exerted so much influence over public opinion, or where it enjoyed so high a measure of esteem among its citizens. And he was reminded that their meeting that evening was to unite in the celebration of the opening of the new hall and laboratories of the Pharmaceutical Society in Edinburgh. They rejoiced in everything that added to the convenience, and usefulness and influence of the Pharmaceutical Society, and those other societies which did great work for the public, and they gratefully acknowledged that to those men, or rather the predecessors of the men whom this Society to-day represented, as well as to bygone great men in other departments of medicine, they owed much of the reputation of this city in the world's eyes. They had, as time went on and the town grew old, to make certain changes and adapt the old system to the new, and those changes were more difficult in a town where one was trammeled by a history of the past, where one must have regard to the conservation of the monuments of past history and persons passed away. That made improvement schemes in Edinburgh have peculiar difficulty. The chairman had already referred to the fact that he himself had been associated with the initiation of very large improvement schemes. He assured them that to further the conservation of the historical relics and the historical figures of this town, while at the same time making provision for the better health of the citizens, was a very anxious and serious matter. He would not willingly throw down one stone of the houses of Old Edinburgh that could possibly be maintained, and yet at the same time the world must be fitted for the men who lived in it to-day, for they could not live from day to day on memory and sentiment, and if the past was to be conserved, make the best compromise that was possible in the circumstances. They were sincerely desirous to keep up the reputation of the city for beauty, to keep up its attractions in every possible direction, and to make its institutions, as far as they had to do with them, the greatest possible good to its citizens, and to the world at large, for they knew something, usu-
science, and especially the sciences connected with medicine. He did not know the nationality of the gentlemen praetising pharmacy in the city, but he had often been struck by the number of nations represented in the roll of the classes at the University. For some time ago he had occasion to look up the nationality of the students of alchemy attending the largest class in the faculty of medicine, and he found that less than one half were Scotsmen. There were about as many Englishmen as Scotsmen—he thought something like 45 per cent., were Scotsmen and 45 per cent. Englishmen, and the rest from all parts of the world. If the alchemist, who was making a name for an international university which certainly was very good for themselves. Here away in the north they would be cut off from that width of view and broadness of mind which was to be gained by associating with men belonging to other nations were it not that their institutions had brought other nations to them to influence their young men. He trusted that the health of the community would go on improving. He had no doubt it would. He had no fear whatever that the fees of doctors or the drugs that would be sold would be in the least degree lessened by any improvements that might be made, and he did not think it would be longer in order to pay more and to buy more. There was no such calamity for either physician or druggist as the death of a patient. He thanked them very much for their kindness.

Professor Sir Thomas Grainger Stewart, who, on rising to propose "The Pharmaceutical Society of Great Britain," was warmly received, said he felt it no easy task to rise to propose the toast of the evening when so many other toasts were yet to be proposed, and several had already been presented so eloquently and responded to so well. But at the same time, it was a privilege to be there as a guest of that distinguished company and to share that honour rejoiced at being a guest on that occasion. He felt it a very special honour that he should be called upon to propose the toast of "The Pharmaceutical Society of Great Britain," coupled with the name of its eminent President. It was always interesting to watch the processes of evolution and differentiation in men's work. In the early stages of society it would seem as if each man did for himself well-nigh everything, and for long many duties continued to be performed by the same individual. But as civilisation advanced there was a time when the only consequence of one's knowledge and different individuals took them up. The process was just such as one could trace in the gradual development of the animal series. In the lowest type one found all the functions performed by rudimentary organs scarcely differentiated, but in the higher type to what a point did differentiation go! So it had been in the history of the great profession of medicine. There were in remote periods those who were priests, physicians, surgeons, obstetricians, pharmacists, all in one, but they had become separated, and now physicians and surgeons formed separate classes, as they saw represented by the heads of the great royal colleges who were present that evening, and the pharmacists had grown into an independent body, as was abundantly testified on that hospitable occasion. There seemed no limit to the degree to which differentiation was taking place in medicine, and no doubt on the whole species of organisation our system of medicine we have the disadvantages so long as it was not carried too far, and was associated in every instance with a high standard of general professional culture. The kind of specialist who threw a light like that of a policeman's lantern upon the individual subject was fitted to do good, but it was a disadvantage that sometimes these lantern rays were surrounded by a wide area of utter darkness. Diffusion of light generally was necessary, as well as concentration on particular subjects. He had of late been much interested in the career of a famous alchemist, whose name used to be familiar to all the students attending the class of Sir Robert Christison and Mr. Lally. He might be a type of the kind of knowledge which existed in his day on the topics with which this learned Society dealt just at the time when they were busy in Scotland preparing to defend themselves against the English on the field of Bannockburn. Raymond Lully, the alchemist, was the first who introduced the convert Mohammedans by a remarkable system, which he propounded in his 'Ars Magna.' He was not only an alchemist, but a philosopher in every department, and in some respects possessed views far in advance of his time. No man in the present day dared pretend to a special knowledge over so wide a range, not even the most distinguished member of the Pharmaceutical Society. It was not likely that differentiation would go far in the Pharmaceutical Society itself, but possibly within it even it might one day come that the field was too marked by the few of them to lament the extinction, and that diffusion should take place in it. If the production of such remedies as antitoxins were to take a prominent place that might of itself constitute a separate branch. The opening of the extended museum and the laboratories in York Place marked an important epoch in the history of the Society. Facilities for study, with free access to the facts, was the first requisite for scientific work in the present day. The provision of proper rooms to work in, and instruments and materials, with judicious guidance and efficient assistance, were the essentials for research. The museum would supply the wants of a few of them; the laboratory would supply them with the other. The old days were long gone by in which doctors were trained by mere apprenticeship, and were afterwards let loose to practise for weal or woe upon the community. Doctors were now carefully trained and educated, and were only permitted to practise when they had attained a certain standard of knowledge. There was a time when each doctor had to be his own pharmacist. Now that had long ceased to be in Scotland, and was disappearing in other parts of the island. The pharmaceutical chemist was educated and examined before he was admitted to practice, and he was admitted: was it a profession? Was it a profession? In his judgment the marks of a profession as distinguished from a trade were that it was pursued by men of culture, and not mainly for the accumulation of wealth. The modern conditions implied that pharmaceutical chemists must be men of culture, and they were pursuing a calling which, although, like other professions, it brought its share of remuneration, yet was not mainly a matter of money-making, but involved many higher considerations. But he would like to say a word about that examination, because he had been an examinee now for a good while in many ways, and his faith in the process of examination did not grow. He found that examinations were very useful up to a certain point, but that they were easily pushed too far. From what he knew of this Society he felt sure it would not push that examination too far—that it would keep the examinations in the right proportion only useful. An examination which was reasonable was not one which rejected two-thirds of the educated candidates who presented themselves. An examination which was reasonable was one which did not bring out the ignorant points of a man, but sought to elicit the points he had learned and trusted and believed that the examinations of the Pharmaceutical Society were of a kind reasonable in
their nature, sufficient to protect the public; but not unduly severe and not unfair to those who had to submit themselves to them. It was his privilege to associate with this toast the name, not of the chairman—justly as one might name him in connection with such a toast actually spoken in Edinburgh, but of wide general culture, and quite famous as an Alpine climber. Early in life he had climbed to the summit of the president of this Society, and he had never come down. Mr. Carteighe was a man of whom the profession might be very justly proud, and he congratulated the Pharmaceutical Society in possessing in him so distinguished a President. He begged respectfully to couple his name with the toast.

Mr. Michael Carteighe, who on rising to reply was received with applause, said he confessed he never, as a mountaineer, expected to have the position which had so often been proposed for him. He could not get to the bottom. He never went up a mountain yet from which he could not get down, but Sir Thomas Grainger Stewart had unfortunately hit on the only failure in his life—that he had got to the top of the Pharmaceutical Society, and could not get to the bottom. He did not know whose fault that was. His friends in the south said, "Are you still President of the Pharmaceutical Society?" and he was obliged to say, with a little nervous trepidation and apology, that he was. And his friends said, "How well you must do them." He had never done them well except when he came to Edinburgh, and he continued to do them well, uniformly so, and he was remarkable that he was not getting people to understand him. But it was really too bad that he should be scoffed at and satirised in this way. It was not his fault that he had a difficulty in getting down.

They knew there was no rope in pharmacy, and one could not get down a troublesome peak without the assistance of someone else. He had tried to rope himself to a few of his colleagues to be let down, in order that they might drop into his place. But they were afraid that the rope would break, and they would not accept the responsibility. But this was not a tingling in his ears. The only danger was that meeting, not only that of friendly and social intercourse, but to celebrate an important fact—the completion, so to speak, of the Pharmaceutical Society of Great Britain in Scotland. The laboratory, lecture hall, and examination rooms, which were to be formally opened the next day, would, he trusted, be found to be all they hoped they would be for the purposes of examination. But he was not concerned with the halls, although during his presidency it had been his privilege and honour to be associated with the purchase of the house in which they in Edinburgh now had a habitation, and he had also been associated with further developing and extending those premises—making them complete, as he hoped they would be, for the purposes of examination. But what he wanted to impress upon that company, containing as it did many pharmacists as well as members of other learned professions, was that they did this in no spirit of criticism or carping, but in the spirit of an ancient city guild that felt that its duty was, with what few shillings it had to spare, to expend them as far as possible in promoting education and examination, and he was sufficiently conscious of the stability of the body he represented to say that he thought the character of their Society would show they had been true to that tradition, and that they had acted, whatever the public might think, in a truly professional spirit in all that they had done. And let him say that no one thing in the course of his presidential career had given him greater pleasure than the fact that from this time forth pharmacy in Edinburgh, the Pharmaceutical Society in Edinburgh, and the profession in Scotland, would have a home and habitations which he ventured to think would be creditable to the greatest historical traditions, not only of Scotland, but of that great educational city of Edinburgh.

Edinburgh was a centre of education concurring, where there was the highest education, technical and otherwise, whatever technical might mean. They knew what it meant, though town and county councils did not always agree about it; but the view they had taken of technical education was to teach men an elementary knowledge of the principles on which science was based, leaving him to work out the particulars as he went along. That was the view his Council took, and he thought gentlemen in Edinburgh took, and he wished in his heart that in addition to those powers of examination which they possessed, they had also that necessary power which was possessed by nothing but a jury, and that of being acquainted—accountants, veterinary surgeons, dentists, et hoc genus omne. He wished they had power to enforce a proper curriculum, and so adopt those wise suggestions which Sir Thomas Grainger Stewart had referred to, that their examinations might be relatively lenient and considerate, and might not be so searching as to come within the domain of what they might call cross-examination and confession. They hoped, however, to continue to do what they could till they obtained the parliamentary powers necessary for being able to enforce a curriculum, and they did not intend to let that matter rest until they had achieved it. Until that time came they had done the best they could. Both north and south of the Tweed they had had excellent Boards of Examiners, and now they were about to have associated with their Boards, in regard to the sciences of botany and chemistry, teachers of those sciences, who, he hoped, keep them from exacting a knowledge of science which, however good in itself, and however valuable, might sometimes be too technical for the average student. Their object was to develop the sciences of botany and chemistry so far as they could conduct their examinations in this direction, that the chemistry examination of the Pharmaceutical Society should be the chemistry taught everywhere and anywhere, and that the botany examination should be the botany taught everywhere and anywhere, and not their application to pharmacy direct and indirect. The fact was that those who had grown old in their craft forgot what an immense amount of practical knowledge they acquired day by day. They found that when once they left the student's career they had difficulty in associating what was considerable in a student of twenty-one years in regard to those vague questions always put in examination both on elementary botany and chemistry. He confessed that as he got older, like many other men of greater distinction, he felt himself that the essence of examination in science lay in this: that the person who examined should be in direct personal sympathy with the young, should be associated with the young, should share with them the spirit, but not the wiles, of his work as his children. It was impossible for many of them to say they could fulfil that condition, and he was not sure that it would be any distraction to the dignity of the certificate which the Society awarded if, as in addition to the eminent pharmacists who composed the Boards of Examiners, they had associated with those pharmacists eminent teachers of chemistry and botany. He was going to say something more—that
if they wanted to look to the history of pharmacy without legislation—unaffected by legislation—they would naturally go to that great city of Edinburgh, for there in Edinburgh had developed within the last century a knowledge of the true pharmacy—that was to say, the application of chemistry to pharmaceutical products and their production and application—which was not to be found in any other city in the British Empire. In that city he was quite sure he had the sympathy of everyone when he said that they were responsible for the government of the Pharmacopoeia of the United States, and that the utmost satisfaction and congratulation the influence which the men who had distinguished themselves as pharmacists in Edinburgh had had on general education all the world over.

Mr. Charles Kerr proposed the toast of "The Royal College of Physicians and Surgeons," and in doing so said it was very gratifying for them as pharmacists to have amongst them that night so many distinguished men of the medical profession, for it was always their desire to do all honour to the noble faculty of medicine. The medical schools of Scotland were of ancient and distinguished condition, represented by the achievements of their teachers and the attainments of their students, but also for the great number of original investigators they had sent out into the world. To the student in Edinburgh the College, Minto House, and Park Place were as well known as the Castle, Holyrood, and Scott's Monument were to the visitor and tourist. The Royal College of Physicians and Surgeons had on its roll of members and fellows many of the most illustrious medical men in their country—men who had distinguished themselves for their original work in the science of medicine; others who had brought the art of surgery to a prominence not before attained; others who, as teachers, would have their names handed down on the never-dying roll of fame. The name of Simpson was one which would never fade from the memory of man, and they felt the honour to have at their meeting another of that name, who had so ably carried on and extended the work begun by his uncle half a century ago. As a master of surgery and a teacher of that branch of the profession Dr. McLaren was well known to them all, and he congratulated him on his election to the presidency of the Royal College of Surgeons. He felt pleased that this toast had been allotted to him, for he had a warm interest in the College, which he had been connected with since the College of Surgery over thirty years ago, and those were his happy days, though most of his teachers had gone over to the majority. He should never forget hearing the last lecture the good and godly George Wilson ever gave—a teacher who truly died in harness. He regretted very much that they had not the presence that night of another teacher of his, Sir Douglas McLagan, whose lectures on materia medica he had the great privilege of hearing. He remembered well the grand vigour and common sense thrown into these lectures. He put the subject home to him as an arrow from a bow—a teacher without guile or humbug. He was proud and glad to have the company of that night of another teacher, the only other remaining of his teachers—Dr. Stevenson MacAdam. From him he learned chemistry, and he had now, framed and made a library, a manuscript book, and handwriting, that would be an heirloom in his family. He was much concerned for the dignity of the Royal Colleges, and he was going to take the liberty of making a suggestion on ethics to their presidents and members. Was it not possible to enact some law making it a misdemeanor for a medical man to give a testimony—positive, negative, or of some concoction—good, bad, or indifferent. He had come to know lately to what an awful extent this begging of testimonials and pushing of proprietary make-up drugs had come. He had a son a medical man who was at present engaged in hospital work. His registered address, however, was his (the speaker's) house, and the amount of stuff in the form of pamphlets and brochures that he received was appalling. His wife declared that if it went on much longer they would require to get up a jumble sale to clear the lot. He was sorry to say the literature was mostly of a degrading kind—one would think it was meant for men who had never studied in a medical school. He wished he could bring the profession as well as to the young "grade." If so, he had no doubt it was to the waste basket it was sent with disgust. He was a bit of a Tory in pharmacy, and would exclaim: "Oh, shade of Christianis, to think your grand old work—the bible of the Scottish pharmacist—is to be supplanted by the flippant Yankee pamphlet!" He hoped their college councils would try by some means to stamp out this dollar-hunting abomination.

Professor A. R. Simpson, Vice-President of the College of Physicians, whose name was coupled with the medical profession, said he had the honour to have an opportunity of responding to the toast in that distinguished company, after having been so genially proposed by one of the vice-chairmen. The College of Physicians had been long very intimately connected with the pharmacists of the country. There was a time when the union was so intimate that those of the College were deputed to visit the pharmacists' establishments to see that they were providing the proper quality and sort of drugs for the good of the community. Happily, in the differentiation that had been going on, and the subdivision of labour, the College had been relieved of this part of its functions, and might well wish--and so much the more as such a Society as that was developing more year by year, so as to make it quite unnecessary for the medical profession to consider what kinds of drugs were behind the counters of the leading chemists. He quite sympathised with Mr. Kerr as to what he had said about pamphlets and samples that were sent up and down the country and came to the houses of all the profession. Sometimes he was not quite sure that the remedy lay in the hands of the College of Physicians at all. He thought it should rather lie in the hands of a Society like their own, which would get the chemists to do what they could to get out of such difficulties. So far as the College was concerned, the drugs and pamphlets came in and went to the waste-paper basket. The College of Physicians had had intimate relations with the chemists, but forbade its own members to have anything to do with the business whatever. The College of Physicians was, at one time, rather exclusive in its character; for at the same time that it forbade its fellows to have anything to do with drugs, it forbade them to have anything to do with midwifery and the work of barbers. They had so far changed their opinions that about a century ago they admitted the accoucheur to their fellowship, and one of their members gave the chemists a good deal of work to do in the use of chloroform. They had from time to time allowed them to climb to the eminence of which Mr. Carteige had spoken, as presidents and vice-presidents, and it was clear that that capacity of his had nothing to do with them for acknowledging this toast as they had done.

Mr. Thomas Mabon, Hawick, proposed "The Scottish Universities." He said the toast was one which was always received with enthusiasm in every company of intelligent—and especially educated—Scottishmen. Scottishmen were sincerely interested in their country, in their literature, and of their educational and national history. Their educational system dated back now for over three centuries, and during all those
years it had ever been regarded as the highest ideal to maintain in perfection those great institutions known all over the world as the Scottish universities, and in those institutions to be placed their universities, of the many illustrious men who had adorned their chairs of learning in the past, as well as the equally illustrious men who occupied those chairs to-day, all of whom had contributed to bring world-wide fame to our country. He coupled the two with the added name of Professor. They were Professors, Brown, who came of a race of intellectual giants. The immortal John Brown, of Haddington, and Dr. John Brown, the author of "Fat and His Friends," were well-known names, but there were others not so well known as they ought to be. He had in his library two volumes of scientific and literary essays by Samuel Brown, who fifty years ago in competition with Gregory was second in the candidature for the very chair now occupied by their distinguished guest. Some of those essays, notably those on the atomic theory and the history of chemistry, were of absorbing interest to chemists, and could be read with very great profit. In the estimation of his family, Professor Crum Brown had a heavy responsibility, but he had proved himself equal to the occasion. He was one of the few men of whom it could be said that he would be equally at home in any one of half-a-dozen university chairs. By his chemical researches he had become famous as a chemist, a worthy successor to Gregory and Playfair; he had perpetuated the best traditions of the chair of chemistry, his prelections in the class-room bore brilliant testimony to his ability as a lecturer, and by his work on the Edinburgh School Board he proved himself a liberal-minded educationist. He even shone as an ecclesiastical if not as a theologian on the floor of the United Presbyterian Synod.

Professor Crum Brown, in replying, said he felt that the universities of this country occupied a very high and important position in regard to the whole life of the country, and the whole life of the professions of the country, and that he was not fit to speak in response to such a toast. The science which he had the honour to represent in the University was indebted far more to the art of pharmacy than the science of chemistry. The art of pharmacy was older than the science of chemistry, and they had inherited a good deal in chemistry from the art of pharmacy, and there were still many points on which the art was ahead of the science. If the art of pharmacy could learn something from the special scientific studies of chemists, chemistry had a great deal to learn from the special work of pharmacists. The relation of the universities of the country generally, or he might rather take the relation of the education of the country generally to the professions generally — because whatever relation the profession of pharmacy had to the University was really the relation which every profession in the country had to the education of the country — was that while the life and existence of the profession of pharmacy did not depend on the sound education of the country, the well-being of the profession of pharmacy had very immediately to depend on the sound education of the country, and it would not be until the people of the country were educated to understand and see that that which was typified by the quack and his allies was nonsense, and that people in a profession really did deal with the wants and necessities of society, that they would turn to them in a loyal manner, with the feeling that the educational bodies of this country had indeed proved themselves too great to be permitted to be pulled down on them. They would not prove themselves fit for that until they had made nonsense of that kind impossible. They had heard it said that a great revelation of health had been attained, and that the professions of pharmacy and medicine might come to an end. They were not so sure as to turn their attention to improving and raising the condition of health of the community. That was a position which they had already taken up to a very considerable extent. He was very much obliged to Mr. Mabon for the reference he made to his family. He was very proud of belonging to what he was disposed to consider — he did not think they would think he was egotistical — a special family. He hoped that in future he might be worthy of the kind reference made about him.

Mr. John Johnston, Aberdeen, in proposing "The Medical Profession," said that to do justice to this toast from a pharmacist's point of view was almost impossible. Now that the days of jealousy had passed away, the physician and the surgeon asked the pharmacist to join hands with them in stamping out disease and alleviating suffering. Towards this end the chemist sought to be nothing more than the trusted handmaid of the accomplished physician and surgeon, and it must be a satisfaction to the medical profession to know that they had as their colleagues such an educated body of men, capable of carrying out their instructions and assisting them to the fullest extent in their philanthropic work. They were not content to be considered — he did not think they would think he was egotistical — a special family. He hoped that in future he might be worthy of the kind reference made about him.
northern portion of the kingdom their interests were much more complex, the pharmacists had the greatest interest in the development of education and the prosperity of the profession of medicine. Many of them might have been ready to help them. The President of the Medical Council, in London, he made some remarks which were of peculiar interest. He pointed out how the students of medicine in Scotland were increasing. Those, no doubt, in England were also increasing, but those in Ireland were decreasing. But there was a point of greater interest. He also pointed out that the registered practitioners in Scotland had increased greatly in numbers during the last twenty years, whereas during the last five years they had diminished in number to a considerable extent, and in Ireland to a very large extent. He did not think they should overlook the circumstance of this increase. He did not think anyone would doubt that that increase must have a large interest to the pharmacists of the country, because it meant an increase of the requirements that fell to the work of the pharmacist, and showed that there was a very close relation between the medical profession and their medical practitioner. Several times that night they had been occupied in anticipating the inauguration of the extension of the buildings of the pharmaceutical branch. He was glad to see that this extension was not only in the nature of a large hall, but also additional laboratory accommodation. It seemed to him that the purpose of the Pharmaceutical Society was not to increase the extent or stringency of ordinary systematic examination, but rather to test, develop, and encourage the education of their candidates in the more practical part of pharmacy. That he thought was a very correct plan to pursue. The great danger as any other profession which they had exaggerated examination too far, especially in those directions where examinations might be passed by mere cramming. The danger was that candidates after they had passed all those examinations might imagine that they had learned the whole of their subject, whereas they had strictly only learned a very limited part indeed. He thought, therefore, the Pharmaceutical Society if it encouraged the practical work in pharmacy would be doing a great work in developing pharmaceutical education. This incumbrance of examination was extending on all sides. It was, he thought, warping education in all departments. It must quite destroy in the capacity which were altogether false criteria—which were not the criteria that should teach them the standard by which men were to be judged who were fit for actual work, to fill official positions in life. When he spoke of those evils which were growing, not only in medicine and pharmacy, but in all departments of official professional life from the multiplication of stringent and unnecessary restrictions in examination, he could not help inquiring what was the origin of the system. And he believed he had been assisted by friends who were greater experts in archeology and ancient history than he was as to its origin. He believed the first introduction of this system originated in China. It existed to a great extent there centuries ago, so that no position in that country could be held without a special examination being passed. So that they learned from ancient history how that system had developed, and now they learned how that system had failed to give them men capable of performing functions. He had very great pleasure in responding to the toast.

Mr. J. B. Stephenson, Edinburgh, next gave the toast of "Our Guests." They claimed, he said, to be part of the medical profession, and there was a very close relation between the medical profession and the Church. The physician ought to be—and he believed he was—the ally of the minister of religion. He believed there was a real and deep sympathy between the two, and he coupled the name of the Rev. Dr. Alison with the first part of his discourse. Coming to science, he said it went without saying that science was an appropriate subject for them. The President spoke on the topic of whether pharmacists belonged to science or art. He had no doubt that pharmacy was both an art and a science. There were many things in pharmacy which were not scientific, but on the other hand they must all be aware that in the details of their calling there was ample scope for the exercise of the scientific mind and of scientific gifts, and it was certain that their profession had yielded a great many eminent men of science, and within their ranks still they had not a few men who were justly entitled to that designation. Such a man they had in Mr. Brady, of Newcastle, whose death they had scarcely ceased to mourn. They were honoured by the company of his not unworthy successor both in the art and science of pharmacy. Mr. Nicholas Henry Martin, a gentleman whom the Conference had honoured by making him president of that body. He commended to them Mr. Martin as the reason for a rare and unique occasion. With regard to art, he asked them to accept their architect, Mr. Hippolyte J. Blanc, A.R.S.A., not only on the occasion of the present completion of the buildings, but on their original conversion for the purposes of the Pharmaceutical Society ten years ago.

The Rev. Dr. Alison expressed his pleasure at being present as the guest of a Society which occupied so high and honourable a place in the estimation and confidence of the community. He referred to the progress which pharmacy had made since the days of the alchemists, and said the Church recognised, as the toast had so well said, that the medical profession and pharmacy as a branch of it, and the profession of the Church were very closely related.

Mr. N. H. Martin, Newcastle, said that although he felt he was a most unworthy successor to Mr. Brady to be mentioned in connection with science, he loved it. It was to him the source of all his happiness, as well as contributing to his livelihood. Pharmacy was in its essence a profession, and in the future those who desired to carry on pharmacy as a branch of medicine must exercise it in the manner of the Champagne. He had valued the training and education to exercise the art of pharmacy in the spirit of science and the spirit of a profession, and then only would they deserve to have their health proposed and drunk in connection with such a toast. He felt greatly honoured in replying on behalf of the British Pharmaceutical Conference.

Mr. Hippolyte Blanc also replied.

Mr. Walter Hills, London, proposed "The North British Branch." He said that some two or three years ago the question was raised at the Pharmaceutical Council what is the North British Branch. That led to a definition having been made which they would find in the pages of the Pharmaceutical Journal, and the success of the last few years had proved the wisdom of the definition. He thought the success was due in the first instance to the wisdom of those gentlemen who lived in Scotland, and who were then members of the Pharmaceutical Council—having been the origin of the society. He felt sorry was not able to be there that night, and to Mr. Borland, who was also a member of Council at that time. Since then they had had as representatives of Scotland Mr. Watt and Mr. Storrar, Mr. Johnston and Mr. Young, and they had all aided by their wisdom, and had helped to bring about the feeling between those who lived in the north and south which they all rejoiced in at the present time. The definition he wanted to give in the first instance of the North British Branch was a very wide one—al
the Scottish branches, whether they belonged to the Society or not, for if they were not members now he would not be in the future. In the second place, he wished to define the North British Branch as all those associated with the Pharmaceutical Society, and with this toast he wished them all prosperity—greater prosperity than they now had. To get a closer definition still, he wished to couple this toast with the executive of the North British Branch and the Scottish Board of Examiners, who had done such excellent work in the past. They who lived in the south were very much indebted to those gentlemen who gave their time to look after the interests of the Society north of the Tweed. He had had the opportunity of discussing with the new the new hall and laboratories, and he was really jealous of the splendid rooms they possessed, and the accommodation for practical dispensing and other examination work. He congratulated them on the splendid premises they possessed. He coupled with the toast the name of Mr. John Nesbit, their chairman.

The Chairman, on behalf of the North British branch, thanked the meeting for the kind way in which Mr. Hills' remarks had been received.

Mr. W. Martindale, London, proposed "The Board of Examiners for Scotland." He said the examiners had always stood like hard-hung Scotchmen to their duties, and held the balance fairly between the candidates, and he knew they would work in unison, as they always had done with the Board of Examiners in London. He coupled with the toast the name of Mr. John Nesbit, the Chairman of the Board.

Mr. John Nesbit, in replying, said he was sure he was only expressing the feelings of every member of the Board when he said they were gratified that the gentleman who had proposed the toast was one whose name was a household word among British pharmacists. He did not think examining boards were generally popular, and he did not think their examining waen any degree different from that of other Boards. They had difficulties in their examinations, but endeavoured as far as possible to do their duty to those who came up before them, and also to the public. They did not always get thanked for that, and it was gratifying to have such aboys of gentlemen as were present thanking them in this way they had done—for they know that at that meeting there were many professors and gentlemen who were examiners, and the majority had been examined, and therefore knew something about it. He wished to say he thought some misapprehension had arisen about their present premises, and the members were proud of them, and all would agree that they might well be proud of them, and he thought they had really been required. But he thought that some, like Professor Fraser, were under a misapprehension. The laboratory was only for examination and not for teaching purposes, and in that sense they were different from those in London, but he hoped the time would come when they could have laboratories fitted up for teaching purposes also.

Mr. Edward Evans, Liverpool, gave the toast of the Chairman; Mr. Robert Hampson, Treasurer of the Pharmaceutical Society, London, proposed the Vice-Chairman, and Mr. Storrar, Kirkcaldy, proposed Mr. Bremridge, Secretary of the Pharmaceutical Society, and Mr. Rutherford Hill, Assistant Secretary, all of whom briefly replied.

The evening's proceedings were enlivened by songs by Dr. G. Kennedy, and Messrs. T. Thompson, Somerville, Shaw, Charles Taylor, and Raoul de Dreuix Kunz, the latter also acting as accompanist.

The company broke up at an early hour of the morning, after singing "Auld Lang Syne."

EXPORT TRADE OF YEAD, PERSIA.

OPIUM.

Of the exports of Yead the most important is that of this drug. It was more largely grown in this province than anything else in comparison with their respective values. Various causes have lately conducted to a decided falling off in the cultivation of the poppy. In a good year the total output of Yead was some 1500 cases, each case weighing about 130 lbs. An average output would be about 1000 to 1200 cases. In speaking of the opium of Yead, I include not alone that only grown in the province, but also that produced in Khorrassan, Tabases, and even in the Herat district. The crude stuff is sent to Yead, where it is manufactured. During the past year, viz., 1891-2, the crop has been but a small one. The prices ruling in China and London were low and not remunerative, consequently only about half the usual amount was sown in the Yead district, and this more for speculative purposes than for anything else. To still further reduce the output the crop, for want of proper spring rains, was a practical failure. Hence the maximum quantity of opium manufactured in Yead was some what under 500 cases. 152 lbs. of the crude material in Yead makes one case of 130 lbs. manufactured article. Of Khorrassan's crude material 195 lbs. makes one case of 130 lbs. A certain portion of the crop is specially manufactured for consumption in the local markets of the country, and is almost entirely supplied by Yead. It is made into sticks' and is used for smoking and eating. Opium smoking is very prevalent in Yead, and it is said that more is used in this place in that way than in any other town in Persia, with the single exception of Kerman. This habit is gaining ground daily throughout the country. In years past adulteration of the drug was very common, but owing to many and heavy losses by having his cases thrown on his hands, or else being sold at 50 per cent. under current rates, the Persian merchant has in this case learnt wisdom, and has almost entirely discontinued the practice.

ALMONDS.

These are now mostly exported to Bombay, but in good years, i.e., when the European crop is not an average one, kernels, both sweet and bitter, are exported to England. Last year the export was about 1,040,000 lbs. This year there has been a very large decrease.

ASAFOETIDA.

There used to be an export of some 500,000 lbs. of this gum, about 150,000 lbs. being from Yead and the balance from Tabbas, but owing to the way it was adulterated the price has greatly fallen, and in consequence the trade has nearly died out. In neither of the last two years has one tenth of the amount been exported.

MADDER ROOTS.

Adulteration and a consequent declining market has also practically killed the export trade in this article, which used to be fairly large with Bombay. Prices have fallen from 1s. 8d. per 13 lbs. to 4d.

SAFFRON.

Saffron was sent into the Yead market from Buragird and thence exported to Bombay. Adulteration has produced the same result as in the previous cases. - Commissar Report.
THE COUNCIL MEETING.

After the reading of the minutes of the previous meeting last Wednesday, the President drew attention to the recent death, at the advanced age of ninety-one, of Mr. William Hooper (see page 495), one of the few remaining founders of the Society, who was in his time a typical pharmacists of the older school, a very successful man of business, and a collaborator with Jacob Bell in the early efforts to make the Pharmaceutical Society a federation of the trade. On the motion of the President, seconded by Mr. Hampson, it was resolved that, on behalf of the Council, a letter of condolence should be sent to the widow.

The report of the Finance Committee did not refer to any but matters of routine either in regard to receipts or payments.

The formal appointment of Superintendents of written examinations and of their deputies was then made, as set forth in the lists at p. 477-8.

On the recommendation of the Benevolent Fund Committee, two grants of twenty pounds each, one of ten pounds and one of five pounds were ordered to be paid. In speaking of the good service rendered by these grants, the Vice-President mentioned the interesting fact that one of the recent recipients of a grant happens to be a direct descendant of John Dalton, one of the first honorary members of the Society. In connection with the discussion of the mode of electing annuitants, Mr. Cross referred to the circumstance that a large number of votes have been placed at the disposal of the Committee, as an illustration of confidence on the part of subscribers to the Fund, and as showing the assistance that can be rendered by them in facilitating the election of annuitants.

In the report of the Library, etc., Committee, the letter received from the Chemists’ Assistants’ Association on the subject of post-graduate courses of lectures and laboratory demonstrations was mentioned as having been carefully considered by the Committee. Though it was not thought desirable to recommend the adoption of the course suggested, the Committee considered that in all probability the Council would be willing to authorize advanced courses of instruction in the higher branches of pharmaceutical work in the event of a desire being expressed by a sufficient number of pharmaceutical chemists. The President gave more precise expression to the limits of this disposition by stating that the term “post graduate” must be understood as meaning that the Major examination had been passed. To that extent the Council would be glad to support any scheme tending to the promotion of pharmaceutical knowledge.

In notifying the resignation of Mr. Abraham as a member of Council, the President gave expression to his sense of the services he had rendered in that capacity, and as the representative of an historic house, regretting the loss of his assistance the more as it is partly due to the effects of the railway accident Mr. Abraham met with some years ago, and suggesting that, on behalf of the Council, this feeling should be communicated to Mr. Abraham. In seconding the motion, the Vice-President informally drew attention to the circumstances that there are at present only five members of Council actually resident in London, and in this respect suggested that in filling up the vacancy the requirements of executive work should be duly considered.

A letter received from the Colonial Office, in which the Marquis of Ripon requested the Council to forward any observations that might be requisite in reference to the Act passed by the Legislature of Barbados for regulating the practice of pharmacy in that island, was referred to the Library, etc., Committee to deal with.

In reporting that, together with some members of the Council, the President had attended the inauguration of the Society’s new premises in Edinburgh, expression was given to the gratification experienced at the excellence of the arrangements which have been made for carrying on the examinations. The part taken in that work by Mr. Laidlaw Ewing, the Chairman of the Executive, and by Mr. W. Hill, the Assistant Secretary, was mentioned as calling for special appreciation by the Council, as well as in Scotland where it has given rise to general satisfaction. The other members of Council present at the inauguration, concurred in the opinion that the accommodation now provided in Edinburgh had been carried out with great regard to utility and economy, and that the reception accorded to
them had been marked by the hearty hospitality always characteristic of Scotchmen.

The report of the General Purposes Committee included recommendations as to the election of members of the Board of Examiners for England and Wales, and the President, in moving the adoption of the report, entered into a full explanation of the proposed alterations, dwelling especially on the advantages to be anticipated from the appointment of professional examiners in the subjects of chemistry and botany, and on the reasons for the selections which had been made by the Committee. The motion was formally seconded by the Vice-President, and eventually carried unanimously. But Mr. HAMSPH, while entirely coinciding with the spirit of the President's remarks, expressed the opinion that it seemed to him unfortunate such important changes had been brought before the Committee at a late hour on the previous evening. However desirable the introduction of teachers into the Board, he felt some hesitation about the appointment of the Society's own professors. Mr. ATKINs emphasized that opinion and wished his sense of doubt to be recorded as a dangerous signal. Mr. SCHACT and Mr. HARRISON followed in the same spirit. On the other hand, Mr. MARTIN, Mr. ALLEN, Mr. MARTINDALE, and Mr. HILLS supported the views expressed by the President, who, in reply, pointed out that the course of action recommended by the Committee has already been adopted by every other qualifying body in the conduct of their examinations.

A vote of thanks to the members of the Boards of Examiners was then passed, especial mention being made of Messrs. CODER, FLETCHER, GREENISH, and TAYLOR, who retire from the English Board, and of Messrs. GIBSON and NESBIT, who retire from the Scottish Board.

The legal portion of the report stated particulars of the progress made with cases placed in the solicitor's hands, showing that several defendants have paid penalties, and that some cases await trial. In several other cases which have been reported to the Committee proceedings were ordered to be taken.

LECTURES ON DIPHTHERIA.

On Tuesday evening, at the Central London Throat and Ear Hospital, Gray's Inn Road, Mr. LENNOX-BROWN delivered the first of a course of clinical lectures on "Diphtheria," in which he dealt with bacteriological observation as a means of determining doubts in diagnosis. The lecturer commenced by stating that from his early recollection of diphtheria when a pupil, he had never been able to agree with the opinion as to croup and diphtheria being identical, and that by a logical inference every case required the same treatment. In this disagreement he had been supported by the main body of general practitioners, both in the metropolis and the provinces. Bacteriological researches were now proving that something like forty per cent. of the cases believed to be diphtheritic were not so, and it behoved all practitioners to use every method of examination which would differentiate the real from the false.

The lecturer recited the history of sixteen cases sent for treatment as diphtheritic, showing on the lantern-screen or by enlarged drawings the portraits of the throats of the patients taken at the bedside, together with the corresponding photo-micrographs of bacteriological specimens of the membranes in each example. The result was to strikingly illustrate the power bacteriology possesses to enforce or to modify the bedside diagnosis. All the patients from whom the cultures were taken had been notified into one of the metropolitan hospitals for infectious diseases as suffering from diphtheria, but nearly one half had been proved by bacteriological examination of the throat exudation to be suffering from one or other of the forms of pseudo-diphtheria, of which, with the simple and compound form of true diphtheria, the lecturer classified and described eleven varieties.

Mr. LENNOX-BROWN stated, in the course of his address, that so early as May, 1887, he had in the second edition of his work on 'Diseases of the Throat,' advanced the view that the principal cause of death in diphtheria is the poisoning of the system by fermentative products of the specific organism. It was nearly two years before the truth of that theory, derived from bedside experience and sharply criticised at the time, was confirmed by the experiments of ROUX and YESSIN, BRIGER and SIDNEY MARTIN, and the modern treatment of diphtheria by antitoxin is based on that important circumstance.

It was announced that the second lecture would be delivered at the same hospital on Tuesday the 18th at 4.30 p.m. The subject will be "Doubts in Diagnosis as Determined by Clinical Observation." Medical practitioners are invited to attend.

THE CONSTITUTION OF THE ATMOSPHERE.

The popular interest excited by the announcement that a hitherto unobserved constituent of the atmosphere had been discovered by Lord RAYLEIGH, had no doubt considerably subsided since the meeting of the British Association at Oxford; but the statement made by the President of the Royal Society at the anniversary meeting, that he regards this discovery as "the greatest scientific event of the past year," will naturally awaken curiosity as to the results of the further investigation, which is now being carried on vigorously. So far, it appears that the results arrived at by Lord RAYLEIGH afford a remarkable verification of the remarks
made by Lord Kelvin, as the President of the British Association, in 1871, as to the importance of accurate and minute measurement, though it may seem to the non-scientific imagination a less lofty and dignified work than looking for something new. On that occasion it was pointed out that nearly all the grandest discoveries of science have been the rewards of accurate measurement and patient, longcontinued labour in the minute sifting of numerical results. This fact is illustrated by the mode in which Lord Rayleigh's discovery was arrived at, as a result of investigations originally undertaken with a view to testing the validity of Prout's hypothesis that the atomic weights of elementary substances are expressed by whole numbers. In the course of that enquiry the desirability of re-determining the densities of some of the principal gases became apparent, and that arduous work, undertaken by Lord Rayleigh in 1892, has been since continued with unremitting application. Among other gases operated upon, nitrogen was found to give rise to most unexpected and disturbing difficulties in obtaining concordant results as to the density of the gas obtained from different sources. The gas obtained by abstracting water vapour, carbon dioxide, and oxygen, from atmospheric air, proved to be slightly denser than the nitrogen gas obtained from nitric or nitrous oxides, or from ammonium nitrite. Hence it was inferred that atmospheric nitrogen is a mixture of nitrogen with a small proportion of some heavier gas, hitherto unknown. With the assistance of Professor Ramsay, Lord Rayleigh succeeded in isolating this gas. The methods adopted were to remove nitrogen from atmospheric air by absorption with metallic magnesium, and also by the old process adopted by Cavendish of passing through it electric sparks. The nitrous compounds thus produced were then separated by absorption into a caustic alkaline solution.

THE INSTITUTE OF CHEMISTRY.

There seems to be a strange absence of harmony among the Fellows of the Institute of Chemistry, some of them being disturbed by unaccountable and inexplicable relations which should exist between them, while others consider that there should not be any doubts on that point. With the view, probably, of relieving any Fellows who suffer from perplexity on that account Professor Tilden was induced to deliver, last Friday evening, an address conceived in the spirit of Baxter's "Helps over the Stile, etc.," and not inappropriately characterised by him as a sermon. After a long and somewhat desultory discussion, the President tersely summed up the whole matter in the two words "Be honest." This procedure is suggestive of that adopted in the nursery legend by the old woman who lived in a shoe, and it may be hoped that its effect will be attended with an equal degree of finality.

EVENING MEETING IN LONDON.

An evening meeting will be held at 17, Bloomsbury Square, W.C., on Wednesday next, at 7.30 p.m., when two papers will be read by Mr. E. M. Holmes, Curator of the Pharmaceutical Society's Museum, entitled "Notes on Opopanax" and "Eucalyptus Oil." A paper will also be read by Mr. Joseph Lees, entitled "The Sphagmites."

PRESENTATION TO MR. T. C. W. MARTIN.

On Wednesday last a meeting was held at 16, Bloomsbury Square, for the purpose of presenting a prize of 175 guineas and an illuminated address to Mr. Thor. C. W. Martin on the occasion of his completing his fiftieth year of association with Messrs. Maw, Son and Thompson. A large number of ladies and gentlemen were present, Mr. E. Butt, Chairman of the Committee, being in the chair. The Chairman, in opening the proceedings, said that the Committee had accomplished the object for which it was formed, in a manner which he hoped would be satisfactory to all concerned. Mr. Martin commenced his career in life fifty years ago, when he was a lad of fourteen summers, with the late Solomon Maw, the predecessor and founder of the present firm of Maw, Son and Thompson, and he was with that firm still.

He had known Mr. Martin for nearly forty years, and thought he was entitled to style him his old friend. Much of the success of pharmaceutical dances might be attributed to the admirable manner in which he carries out the duties which appertained to the office of M.C., and the Benevolent Fund of the Pharmaceutical Society had benefited very considerably owing to Mr. Martin's exertions. He believed also that the scheme of appointing divisional secretaries in London, which the Council of the Society adopted several years ago, first emanated from suggestions made by Mr. Martin at a time when considerable exertion was made by its chief supporters to try and extend the interest which all pharmacists ought to feel in that Fund. In conclusion, he asked the Honorary Secretary, Mr. Fred Banks, to read the address which was about to be presented to Mr. Martin.

Mr. F. Banks, the Honorary Secretary, then read the address, and the Chairman presented it, with the purse, to Mr. Martin, remarking that money alone did not represent the esteem and respect in which he was held by his numerous friends. He hoped both Mr. and Mrs. Martin would long live to enjoy health and prosperity.

Mr. Cartwright expressed the pleasure with which the Council had acceded to the request of the Committee to allow the presentation to take place in that room. The Council was always glad to place its rooms at the disposition of anyone connected with the trade for any legitimate purpose. In particular the Council was glad to show its respect for one who had done so much as Mr. Martin had for the Benevolent Fund.

Mr. Robinson and Mr. Phillips having also added a few words, Mr. Martin thanked his friends for this mark of their kindness. He referred to the Benevolent Fund, to which he considered it the duty of every chemist to contribute, and concluded by repeating his thanks, with those of his wife and daughter.

A vote of thanks to the Chairman and Committee, proposed by Mr. Bottle, was carried, as was also a motion by Mr. Robinson to the Council of the Pharmaceutical Society, for giving the use of the hall, and the proceedings then terminated.

BENEVOLENT FUND ELECTION.

A meeting for the election of four annuitants on the Benevolent Fund will take place on Tuesday next, at 12 o'clock precisely.
MISCELLANEOUS NOTES.

In a paper recently read before the Berlin Medical Society, Dr. HANSEMANN, Professor VIRCHOW’s assistant, denied that Löffler’s bacillus was the cause of diphtheria. It was often met with in healthy individuals, and sometimes absent in cases of diphtheria. At the same time, it probably stands in some relation to the disease. It was also stated that the diphtheria of guinea pigs and other animals is different to that affecting human beings, and that Dr. Berhino’s assertions that serum conferred immunity from and cured diphtheria were unproved. Moreover, it is doubtful if serum is harmless, since it may induce disease of the kidneys in patients suffering from diphtheria.

A paper on the utilisation of the Agave as a fibre-producing plant was read at the Imperial Institute on Thursday, November 29, by Mr. A. VANDENDEURRECH, the chair being taken by Professor ARMSTRONG, F.R.S., President of the Chemical Society.

Important improvements have been effected recently at the Middlesex Hospital, including the construction of a new operating theatre with seats for 150 students. The cost will be between £4000 and £5000, and subscriptions are solicited. The installation of the electric light at the Hospital is said to have resulted in a saving of over £300 in one year for cleansing operations alone.

We regret to record the death of W.M. FOSSETT E. HORELL, on Friday, November 30. Mr. HORELL won the Silver Medal offered by the Pharmaceutical Council for the best Herbarium in 1889, became a Redwood Scholar under the old regulations in 1891, and passed the Major examination in October, 1893.

The Pharmaceutical Football and Cricket Club will hold its annual smoking concert at the Holborn Restaurant, on Tuesday next, December 11, at 8 p.m., when Professor Green, Sc.D., M.A., Dean of the School of Pharmacy, will take the chair. Former students of the School and other friends can obtain tickets (1s. 6d. each) from the Secretary to the Club, Mr. T. TICKLE, 17, Bloomsbury Square, W.C.

At Berlin, on Sunday last, a monument to Mitscherlich, the famous chemist, was unveiled in the Chestnut Grove near the University.

A considerable quantity of anti-diphtheritic serum has been successfully prepared by Dr. KLEIN, who has placed a supply in the hands of the editor of the British Medical Journal for distribution to provincial hospitals and also offered supplies to fifteen metropolitan hospitals.

The subject of company promoting and kindred matters continue to be investigated by the committee appointed by the Board of Trade for that purpose, the latest meeting being held under the presidency of Lord Davey on Thursday, November 29.

In addition to the lectures by Professor J. A. FLEMING on "The Work of an Electric Current,” the programme of the Royal Institution for the recent session includes courses on “The Internal Framework of Plants and Animals,” by Professor CHARLES STEWART; “The English Humourists of the Nineteenth Century,” by Mr. W. S. LILLY; "Meteorites," by Mr. L. FLETCHER; "Three Periods of Seventeenth Century History," by Dr. S. R. GARDINER; “Animism,” by Dr. E. B. TAYLOR; “Stained Glass Windows, etc." by Mr. L. F. DAY; and others by Dr. A. C. MACKENZIE and Lord RAYLEIGH; whilst Professor DEWAR will lecture on “Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air,” at the first Friday evening meeting, on January 18.

In a case before Judge BACON, at the Bloomsbury County Court last week, a local dentist was sued by a patient, who sought to recover the amount paid for a set of false teeth. A full set had been supplied at the not exorbitant price of 30s., but it was alleged that when delivered two teeth were missing, the set would not fit, and the rubber of the gums met. Judgment was given for the plaintiff on condition that he returned the teeth, which he expressed himself as more than willing to do.

Last Sunday was observed in more than eighty places of worship in London and elsewhere as "Museum Sunday," being the third occasion when sermons in favour of the Sunday opening of museums were formally delivered. According to the President and Honorary Secretary of the Sunday Society, the Trustees of the Soane Museum and of the Dulwich Gallery have agreed to open their art collections on Sunday afternoons, eight special exhibitions in London being thus open to the members of the Society, as well as eighty-five institutions throughout the country, supported by national and municipal taxation.

The death is announced of Mr. THOMAS BELL, aged 78, brother of Sir LOWTHIAN BELL, and a member of the firm of BELL BROTHERS. Mr. BELL was at one time a partner in the Walker Iron Works, and subsequently, in conjunction with Sir LOWTHIAN and Mr. JOHN BELL, established the Washington Chemical Works and the Clarence Iron Works.

The old-established business of Messrs. CORBYN, STACEY & Co., in Cheapside, will in future be carried on by Mr. A. W. WARING, who has been with the firm for the past twenty years.

We regret to announce the death of Mr. EVAN LEWIS HICKIE, pharmaceutical chemist, of Chelsea, who had been a member of the Society since 1864, and was one of the Divisional Secretaries for London.

Mr. W. H. SYMONS, L.S.A., a member of the Pharmaceutical Board of Examiners for England and Wales, who recently received his diploma as M.R.C.S., has now taken the degree of M.D. at Brussels.

Arrangements have been made by the British Institute of Public Health for a lecture to be delivered on the antitoxic treatment of diphtheria by Dr. G. SIMS WOODHEAD, the Director of the Research Laboratory of the Royal Colleges of Physicians and Surgeons, in the Examination Hall, Victoria Embankment, on Friday, December 7, at 5 p.m.
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.

Wednesday, December 5, 1894.

Present—

MR. MICHAEL CARTEEHE, PRESIDENT.

MR. WILLIAM GOWEN CROSS, VICE-PRESIDENT.

The minutes of the previous meeting were read and confirmed.

ELECTION OF ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Donellan, Arthur William Ernest, Crews.
Thompson, Charles John Samuel, Liverpool.

ELECTION OF ASSOCIATES.

The following, having passed the Minor examination, and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Acock, James Elworth, Sheffield.
Scott, George L., Harrow.
Whaley, Charles Edward, Newcastle-on-Tyne.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who had severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and druggists:—

John Douglas, 34, Whitefriargate, Hull.
Henry Charles Drake, 170, Humberstone Road, Leicester.
John Thomas Hancock, 55, Frogmore Street, Aber- gavenny.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a restoration fee of one shilling.

THE LATE MR. WILLIAM HOPPER.

The President said he heard when in Edinburgh last week of the death of one of the founders of the Society, Mr. Wm. Hopper, who died at Surbiton at the advanced age of ninety-one. Mr. Hopper was the well-known pharmacist of Russell Street, Covent Garden, and was known in early days as a typical pharmacist, a man who believed there was nothing too good for his pharmacy or laboratory, and that economy was no principle which a pharmacist should consider. He was in the habit of saying to his assistants and pupils that the best was good enough for him, and the best of everything he would have, if possible. His name was formerly a household word in connection with high-class pharmaceutical preparations, and although never, as far as he knew, an officer of the Society, he was sympathetic in all that was done, attended the early meetings, and was associated with Jacob Bell and the rest of the founders at the beginning of the Society. He was generous to those who succeeded him in business, and to all who had been associated with him. His wife, he was happy to say, survived him, and he would suggest that he be authorised to write a letter of condolence to her.

Mr. Hampson said he should be glad to second a motion to that effect. When he came to London in 1871 he had the pleasure of meeting Mr. Hooper on a business matter, and he was very much struck with his strong individuality. He was distinctly a man far above the average, both highly honourable, and at the same time of great business capacity. He was a most amiable man, and would long be remembered.

The President, in putting the motion, said it would be interesting to the members to know that there were no less than ten of the original founders still living in various parts of the kingdom, ranging from Cockermouth to Brighton, and most of them, he was glad to know, were well and hearty.

The motion was adopted.

REPORT OF FINANCE COMMITTEE.

The report of this Committee was of the usual character, and recommended sundry accounts for payment.

The President (as Chairman of the Committee), in moving its adoption, said it contained nothing which called for special reference. On the Benevolent Fund account during the last election in December, the figures would probably be higher. The donation account remained as it was last month, and the Orphan Fund was slightly increased by dividends on Consols. Seven guineas had been received from the honorary secretary of the Junior Chemists' Ball.

The report was unanimously adopted.

SUPERINTENDENTS AND DEPUTY-SUPERINTENDENTS OF WRITTEN EXAMINATIONS.

The following gentlemen were appointed superintendents and deputy-superintendents of written examinations and assistant local secretaries respectively:—

Superintendents.

Aberdeen.............. Strachan, Alexander.
Birmingham........... Thompson, Charles.
Brighton.............. Gwatkin, James Ross.
Bristol.............. Stroud, John.
Cambridge............ Deck, Arthur.
Canterbury........... Bing, Edwin.
Cardiff.............. Munday, John.
Carlisle.............. Hallaway, John.
Carmarthen............ Lloyd, Walter.
Carnarvon............ Jones, J. R. 
Cheltenham.......... Rees, William.
Darlington.......... Robinson, James.
Dundee.............. Hardie, James.
Dundee.............. Stephenson, John Bertram.
Exeter.............. Lake, John Hinton.
Glasgow.............. Currie, William Little.
Guernsey............. Nickolls, John Bate.
Hull................. Bell, Charles Bains.
Inverness........... MacRitchie, David.
Jersey.............. Cole, George.
Kirkwall (Orkney).... Stewart, Duncan.
Lancaster........... Yorke, James.
Leeds.............. Reynolds, Richard.
Lincoln.............. Birkbeck, John Thomas.
Liverpool........... Smith, John.
London.............. Taylor, George Spratt.
Manchester........... Kemp, Harry.
Newcastle-on-Tyne... Cleasby, M.
Norwich.............. Bingley, John.
Nottingham............ Bolton, Charles A.
Oxford.............. Prior, George Thomas.
Penzance............. Shakerley, Benjamin.
Plymouth............. Hunt, Freeman W.
Sheffield............ Ward, William.
Shrewsbury .......... Cross, William Gowen.
Southampton .......... Dawson, Oliver Robert.
Worcester .......... George, Henry.
York .......... Sowray, Joseph.

Deputy-Superintendents.
Aberdeen .......... Clark, James.
Abingdon .......... Ellis, Robert.
Birmingham .......... Prosser, Frank H.
Bristol .......... Keen, Benjamin.
Canterbury .......... King, George.
Cambridge .......... Amos, Daniel.
Cardiff .......... Coleman, Alfred.
Carlisle .......... Pattinson, Michael Herd.
Carmarthen .......... Richards, Jonah Palmer.
Carnarvon .......... Jones, David.
Cheltenham .......... Palmer, Frank Thomas.
Darlington .......... Hutchinson, Rev. E.
Douglas, Isle of Man .......... Young, John.
Dundee .......... Hardie, James Miller.
Exeter .......... Harris, Henry William.
Glasgow .......... Moir, James.
Guernsey .......... Carré, James Hilary.
Hull .......... Stoakes, Benjamin M.
Inverness .......... Bethune, William J.
Kirkwall (Orkney) .......... Webster, Rev. David.
Lancaster .......... Arkle, William.
Lincoln .......... Houfe, Robert William.
Liverpool .......... Buck, Anthony S.
Manchester, etc .......... Swinn, Charles.
Newcastle-on-Tyne .......... Weddall, George.
Northampton .......... Mayger, William David.
Norwich .......... Corder, Octavius.
Nottingham .......... Sergeant, Furlow Ross.
Oxford .......... Thurland, Henry.
Penzance .......... Symons, Netherton H.
Plymouth .......... Woods, William Herbert.
Sheffield .......... Morrison, Charles Orr.
Shrewsbury .......... Bint, Thomas Porter.
Southampton .......... Spearing, James.
York .......... Kendall, Edward Basnipp.

BENEVOLENT FUND COMMITTEE.
The report of this Committee included a recommendation of the following grants:

- £20 to the widow (44) of a member and subscriber, to assist her and her three children to go out to America. (Tottenham.)
- £10 to a registered chemist and druggist (68). (Newport, Salop.)
- £2 to the widow (65) of a registered chemist and druggist, who has had nine previous grants of £5 each. (Forest Gate.)
- £20 to the widow (59) of a registered chemist and druggist, who has an only daughter, a chronic invalid, to support, and is quite without means. (Ealing.)

One case was not entertained, and two stood over for further consideration.

The Vice-President, in moving the adoption of the report, said he had had an opportunity during the last few days of seeing some of the recipients, and in his judgment they were very fitting subjects for the assistance of the Fund. In one case a man of 78 years had maintained himself in a small way until overtaken by illness, and he was sure they were only too pleased to recommend relief in such circumstances. In another case the person recommended for assistance was a direct descendant of one of the first honorary members of the Society, and a distinguished scientist. Having, through no fault of her own, been brought into greatly reduced circumstances, he felt the proposed relief would be cheerfully voted her. He desired whilst referring to this Fund to call attention to the service that might be rendered by subscribers placing their votes in the hands of the Committee. Through some suggestions which had been made in this respect, some 225 votes had already been so placed, and he had received six more that morning. He felt that the Committee for the time being would at all times be only too happy to make the best use of the power with which it might thus be entrusted.

The report was carried.

REPORT OF THE LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

Library.
The report of the Librarian had been received, including the following particulars:

<table>
<thead>
<tr>
<th>Attendance</th>
<th>Total</th>

Donations to the Library had been announced (Pharm. J., November 17, p. 404), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the undermentioned works be purchased:

For the Library in London—

Cyclopedia of Names, supplement to Century Dictionary.
Roscie and Schorlemmer, Treatise on Chemistry new ed., vol. I.
Ostwald, Physico-Chemical Measurements.
Darwin, Practical Physiology of Plants.
Bernthal, Organic Chemistry, 2nd ed.
British Pharmacopoeia, latest reprint, 2 copies.

For the Library in Edinburgh—

Thorpe, Inorganic Chemistry.
Mikendrick, Physiology.
Marshall and Hurst, Practical Elementary Zoology.
Sonntag, Pocket Flora of Edinburgh.
Frankland, Micro-organisms in Water.
Flückiger, Reactions.
United States Dispensatory.
Richter, Inorganic Chemistry.

Museum.
The Curator's report had been received, and included the following particulars:

Donations to the Museum had been announced (Pharm. J., November 17, p. 404), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The School Staff had attended and reported upon the classes.

The Committee had considered the resolution forwarded by the Chemists' Assistants' Association, with reference to post-graduate courses of lectures and laboratory demonstrations, but was unable to recommend the adoption of the suggestion. The Committee, however, desired to express its belief that the Council or the
School Staff would be willing to undertake any advanced course of instruction in higher pharmaceutical education, if a sufficient number of pharmaceutical chemists expressed a definite desire for such instruction.

The President, in moving the adoption of the report, said the Committee had very carefully considered the request made by the Chemists' Assistants' Association, but it had some difficulty in understanding exactly what the Council was asked to do. Assuming that "post-graduate" referred to pharmaceutical chemists, the Committee felt that the request for higher pharmaceutical education to be provided for such men might well be considered. If, on the other hand, the meaning was that the Council should provide evening courses of instruction to qualify Minor men for the Major examination, the Committee could not agree with the suggestion. These young men probably took the term "post-graduate" from the medical profession. Post-graduate courses were given at special hospitals, or in special departments of general hospitals, to medical men who were, in many cases, in practice, and all of whom were on the Medical Register and entitled to practise. It seemed to the Committee that it was no part of the Society's duty to provide specialised work for Minor men in commerce. It makes them proficient in water analysis on any particular department of that kind. Neither was it their duty to provide evening instruction which would enable students to acquire the degree of the University of London, or to pass the examination of any similar body. It was felt, however, as expressed in the report, that if any number of pharmaceutical chemists desired advanced instruction of a truly pharmaceutical kind, not in any special direction but generally, the Council would be willing to assist. He did not think the number who could avail themselves of such instruction would be great, but if such a demand did exist, it had only to be made by a reasonable number of men, and the Council would undertake it. It was not considered that special post-graduate courses should be given, but he was sure the Council would be glad to support any scheme which would tend to the general advance of pharmaceutical knowledge in this part of the country. He hoped that what was really asked for, and therefore could not recommend that the suggestion of the Chemists' Assistants' Association be adopted.

Mr. Hampson said he understood that if higher instruction in any section of study—chemistry, physics, or materia medica—were asked for by a sufficient number, the Council would acquiesce in the request. It was necessary to ask for a general scheme, including all branches.

The President said that was his view. It would be scarcely possible for a sufficient number to be obtained anxious to take advantage of a general scheme.

Mr. Bottte said he did not understand that the Council would be asked to do more than assist in such instruction. Some fees would probably be asked from the students.

The President said the view of the Committee certainly was that those applying should contribute a portion of the expense. They did not believe in giving aleemoneary education of any kind.

The report was then unanimously adopted.

Resignation of Mr. Abraham.

The President said Mr. Abraham had written to him, saying he found it necessary to resign his position as member of Council, as he found it increasingly difficult to spare the time requisite to attend the meetings, and he was unable to get through so much work since his nasty accident some two years ago. He then went on to speak of the kindness he had always received, and to make certain suggestions with regard to the business. He was sure the Council would agree with him that Mr. Abraham should be thanked for the services he had rendered during the short time he had been a member of the Council. He represented a historic house; his father was a member of the Council and was on the Board of Examiners in early days; and both Mr. Abraham and his brother had done a great deal for pharmacy of the highest class in Liverpool. His qualifications were of the highest class, and they were very sorry to lose his services, and still more to find that he should be still suffering from the results of his unfortunate accident. He would suggest that he be allowed to write a suitable letter to him on his resignation.

The Vice-President, in seconding the motion, begged to draw the attention of his colleagues to the fact that there were at present only six who nominally resided in London, and one of these now lived twenty-five miles away. He hoped this would be borne in mind when the vacancy caused by Mr. Abraham's resignation was filled up, because it was of considerable importance in carrying on the executive work of the Society that a sufficient number of members of Council should be available for consultation by the officers. These officers were not members of Council, but he hoped they would not be considered out of place.

The motion was carried unanimously.

Correspondence.

The President reported that a letter had been received from the Marquis of Ripon forwarding an Act passed by the legislature of Barbados for regulating the examination, registration, and practice of pharmacists, and inviting the Council to communicate their observations they might have to offer. He suggested that it be referred to the Library and Museum Committee to deal with; and the suggestion was adopted.

The Meeting at Edinburgh.

The President reported that some members of the Council, with himself, had the pleasure of attending in Edinburgh at the inauguration of the new laboratories and examination hall. Those who then took an interest in the Council part in the proceedings that was really asked for, and therefore could not recommend that the suggestion of the Chemists' Assistants' Association be adopted.
and for himself he felt grateful that Mr. Ewing had consented to serve in an important office, not only from the point of view of the official chairmanship, but from the point of view of social intercourse, and his identification with every branch of medicine and science. In Glasgow, on the preceding Wednesday night (5th) had taken place the annual meeting of the Society, a large number of chemists and druggists, who showed that they were less gratified than were the members of Council at the completeness of the scheme now carried out in the capital of Scotland. The General Purposes Committee at the meeting last night felt it was its duty to increase the salary of the assistant secretary, in view of the future not less than the past, by £50 per annum.

Mr. Hampson said he should like to add his gratification at having been able to take part in the function to which the President had referred, and completely to coincide with the views to which he had given expression. He thought there could be no question that the accommodation now provided in Edinburgh not only compared favourably with their own accommodation here, but in some respects was superior, combining, as the President had said, utility with elegance. Considering the expenses which had been met, he thought the expenditure had been both wise and calculated to give every satisfaction. He hoped one result might be to draw into their ranks gentlemen whom it was desirable to see amongst them, requiring as they did a great accession of strength in both countries.

Mr. Martindale also expressed his gratification at the preparations which had been made, and his own participation in the inauguration. He considered their Scotch friends had a very compact suite of rooms, well adapted for the purpose. They had not been hampered with conditions such as prevailed in London, and he heartily congratulated their Edinburgh friends on the way in which they had been able to complete their arrangements, combining, as he conceived, proficiency with economy. He also gladly re-echoed the expressions of the President and Treasurer as to the thoroughly Scotch welcome extended to the members of the Council who took part in the inauguration.

Mr. Atkins said he felt how much he had lost through being unable to join in the visit, owing to the state of his health at the time. He had known some of their Scotch brethren for years, and could quite understand they were not in the least bit in awe of the representatives of the Society. He was glad that the committee had recommended the Council to increase the salary of the assistant secretary, in whom he had long thought they had a most valuable official, and it would be wise in anticipating the future, to take care that when they had a good man they should retain him. He had long felt the difference in the position which pharmacists occupied in Scotland and England, moving, as they did in Edinburgh, in an atmosphere in which medicine, science, and the higher qualities of mind held a unique position; and he hinted that this step forward might lead to pharmacists securing even a greater share in the privileges thus enjoyed. He was thankful to hear the report which had been given them of the admirable arrangements which had been made, and that some fears which he entertained of possible difficulties as to light and so on had been surmounted or at all events removed by the outlay.

Mr. Johnston said, as a Scotman, he felt great pleasure in hearing that the members of the Council had been so satisfied with their visit to Scotland. That had justified his own impression that when southerners went north they would receive a hearty welcome. As to the work at Edinburgh, at the meetings he had attended he felt everything was done that was possible to secure successful results; and he was satisfied that a better hall and better equipped laboratories would not be found this side the Tweed, whilst in Scotland they had nothing at all like it. With reference to Mr. Ewing, it was a great disappointment to Scotmen to hear that they were likely to lose his services. He was anxious to retire at the last election, but it was felt that Mr. Ewing's services must not be lost until the buildings were finished. He had done his duty well and admirably, and he was sure the members of the Council appreciated the labour and trouble to which he had been put. He was glad to hear that their Secretary in Scotland was to have an addition to his salary, well deserving it as he did. He was to be found at his post morning, noon, and night, and ready to give all the assistance in his power to those who sought his aid.

Mr. Hills said he must say that he, too, was exceedingly gratified with his Edinburgh visit, with the admirable manner in which the Edinburgh executive had carried out the work and with the attention Scotch pharmacists showed him and his colleagues. To tell the truth, he felt a little jealous at the complete way in which the new buildings had been carried out. He only wished they could hope in England to possess themselves in the perfection of their details, and he heartily congratulated their Scotch brethren on what they had accomplished.

General Purposes Committee.

The report of this committee included the usual letter from the solicitors stating the progress made with cases placed in their hands. Several defendants had paid penalties, and some cases were awaiting trial. Several fresh cases of infringement of the Pharmacy Act were reported to the Committee, and proceedings were recommended.

The Committee recommended that an addition of £50 a year be made to the salary of Mr. J. Rutherford Hill, assistant secretary in Scotland, to begin in January next.

Boards of Examiners.

The committee had received the report of the sub-committee and recommended that the following be appointed on the Board of Examiners:—Professor J. R. Green, M.A., Sc.D., Professor of Botany in the Society's School; Mr. A. C. Seward, Lecturer in Botany in the University of Cambridge; Mr. W. H. McLeod, Professor of Science Tripos; Professor Percy Frankland, F.R.S., Professor of Chemistry, Mason's College, Birmingham; Professor McLeod, F.R.S., Professor of Chemistry Cooper's Hill College; Messeer. G. C. Druce, A. W. Gerrard, W. M. Holmes, F. Ransom, J. E. Saul, W. H. Symons, E. White, and A. E. Tanner.

The President, in moving the adoption of the report so far as regarded the appointment of examiners, said he should like to explain that Mr. Corder was ineligible for nomination on account of age, Mr. T. E. Greenish and Mr. Taylor, as senior members of the Board, retired by rotation, and in the case of Mr. Fletcher and Mr. Tanner, they having been members for the same length of time, a ballot had been taken, with the result that Mr. Fletcher retired. The remaining members of the present Board, with the teachers, were recommended for appointment. He should also state that Mr. Nesfield and Mr. Black, who composed the current Board, retired, as the two who had been longest in office. The recommendation for the appointment of examiners followed to some extent from the decision of the Council to appoint on both Boards gentlemen who had been engaged in teaching botany and chemistry. The sub-committee which had this matter under consideration had looked at the matter from
every point of view, and considered that the gentlemen suggested were in every respect the best adapted at the present moment for inaugurating the new system of examination. They felt that in submitting those names they incurred a certain amount of responsibility, which however they cheerfully accepted. For our part, he considered that it was not only desirable that the branch of the subject which should be a member of the Board, but that it would be extremely useful, especially at the beginning of a new system, that there should be a connecting link between the Society and the Board. It was also important that the two Boards in England and Scotland should work as far as possible on exactly the same lines. The question of what was an elementary knowledge of chemistry or of botany was very difficult sometimes to define, and it was considered that those who taught those subjects would be able to define it with greater precision than others. The committees also felt that it would be a great advantage to have men of judgment connected with their own body on the Board. In advocating the new mode of examination he held that the contact of professors from outside with their own members would be productive of good all round. Teachers came into daily contact, and the teachers themselves were aware that sympathy which an examiner always ought to have with the candidates; and it was of the highest importance to select men who had that sympathy. With that view they had chosen for botany, Professor Green and Mr. Seward. The sub-committee felt that the advantages to be obtained by the association of their own professors with the Board overbalanced any disadvantages which might be supposed to arise. There could be no question that Professor Green, from his qualities, was especially adapted for this position.

With regard to the question often raised how far a teacher should be an examiner, seeing that his own pupils came before him, he would say that where there were two examiners it seemed to him there could be no question as to the fairness of the examination. No teacher that he knew of ever examined his own pupils when he was solely responsible. To deal with the Major examination first, that was done non-approved. That practical chemistry would be conducted by both examiners, and each portion would be checked by both; and the same with regard to botany. Therefore, if either had a pupil of his own before him the question of his passing would not be determined by one alone. In the same way in the Minor examination when a pupil was examined in one subject the practical chemistry two examiners would do the work, with one or more other examiners associated with them. In the oral examination the same thing occurred. If they considered the very small number there were of candidates from the School compared with the total he felt there could be no danger either of undue strictness or undue leniency. The present system now being developed under every examining body was distinctly in favour of the teacher examining his own pupils. It was held that the teacher was really the best person to examine them, and that if there were an external examiner by himself this system was perfect. The examinations of the joint Boards of the College of Surgeons and the College of Physicians, and of Dentists, were all carried out practically in this way. In the south nearly all the examiners were teachers. They all had pupils in the respective subject examined, and none of them; the teachers would be in each subject, and they would refer their own pupils to the other examiner, so as to avoid any difficult question that might sometimes be raised as to unfairness or jealousy. Many outsiders seemed to think that these examinations were in the nature of competitive examinations. Of course in such a case a few marks, more or less, made all the difference; but in this case the Board had determined to go on broad general lines, and, with the utmost sympathy for the student, decide whether he possessed sufficient elementary knowledge of chemistry or botany to be put on the Register. For himself, he could not see that there was any difficulty; on the contrary he thought it only right and justice that those who had advanced chemistry and botany, that its officers should from time to time become members of the Board. Of course each case would be dealt with on its own merits. The examiners were appointed annually, and even if re-appointed they could not remain in office longer than four years. It was suggested that next year or the year after an arrangement might be come to, by which an examiner, either in chemistry or botany, should retire, so that the new examiners engaged in teaching should not be appointed all at once. He referred to this subject especially because it was important that the position should be understood. His own feeling in the matter was distinctly in favour of the association of the teaching element. The other day at Edinburgh several observations were made with regard to this subject, all pointing to the importance, not only of associating teachers with the examiners, but, where possible, of associating teachers with the pupils. That idea ran through the whole of the report of the Commission on the new university for London. Many years ago a sort of free-trade university for London was established, and they were now trying to establish something like an antithesis to it in every respect. The ancient universities of Edinburgh, St. Andrew's, Aberdeen, and Glasgow, were immeasurably in advance of English examining bodies in this matter; and he himself thought the names now submitted would make a Board as nearly as possible comparable to those found at those universities conferring qualifications in medicine, surgery, and science. It might be asked why they did not appoint a chemical professor and examiner. But they had to consider the amount of work in which the professors were engaged, and the sub-committee felt that neither Professor Atfield nor Professor Dunstan was free enough to be eligible for appointment. Both were engaged to a very great extent in the other work of their University; and that the relation of botany to its kindred subject, materia medica, and the existence of the Society's museum, all rendered it desirable to appoint Professor Green an examiner at the present moment.

The Vice-President seconded the motion.

Mr. Hampson thought that if he might use the word or two, he would not say on the other side, because he coincided entirely with the spirit of the President's observations, but because he thought it was a little unfortunate that the Committee was asked on the previous evening, at a very late hour, to consent to a very important and organic change with regard to the examinations. With regard to introducing teachers from outside to the Board, he thoroughly acquiesced; but he felt some hesitation with regard to the appointment of one of their own professors. He could not help thinking last night what would their old friend, Mr. Sandford, have said to such a suggestion. He was quite sure he would have required a little time for consideration, and he thought it very doubtful whether he would have acquiesced in the report eventually. So far as the gentleman selected was concerned, he was quite sure the Committee could not deal with him in that capacity, but he had some doubt about the propriety of introducing a professor from the Society's own school on to the Board.

Mr. Atkins said Mr. Hampson had expressed his own feeling on the matter. They had arrived at a point on the rails where the pointman was turning the train on to a new line, or, to put it in another
way, they were to-day making history; and he wished to put on record his sense of doubt as to the wisdom of placing their own professors on the Board of Examiners. As long as the present Board were always to be considered—and also of his consideration and sympathy. At first he had had some misgivings about the wisdom of appointing external examiners at all, but when he came to think over the matter all his objections vanished, but he had still doubts about appointing their own professors. It was said that the practice of teachers examining was growing. Undoubtedly he remembered Professor Michael Foster dealing with that point in a humorous way, and saying that he would remove the dread of examination by examining the men more frequently; but the examinations referred to were, he thought, not quite Martin, as a member of the committee, should apply tests of a man's knowledge along the line of a curriculum. He felt some hesitancy about the effect of an act of this kind on other schools, some of whom were doing honourable work in qualifying men for the examinations. The Society's school was undoubtedly a typical school of pharmacy and medicine, and he should wish to have all suspicion with regard to those who competed with it in the educational market. He felt it right to express those doubts, though he should not move any amendment or vote against the motion. The whole policy of the country in modern times was that everyone should be above suspicion of interest in any matter which came before him; of course he felt that their own professors would be sans peur, sans reproche, but the question was whether they would always be so considered outside, and in the matter of examinations especially there ought to be no possible ground for suspicion.

Mr. Schacht said he cordially agreed with the motion as he understood it, but in supporting it he must not be supposed to endorse everything which had fallen from the President in proposing it, though of course he always received everything he said with the greatest respect.

The Vice-President hoped the impression would not get abroad that they were appointing interested men as examiners. The principle of appointing teachers at all lay at the root of this question, because, when any teacher was appointed, there was a possibility of his own pupils coming before him. He interposed this remark because it did not think Mr. Atkins quite appreciated the full force of his observations. Professor Green would probably have fewer of his own pupils to examine than if a teacher at some other school of pharmacy was appointed. He heartily supported the motion.

Mr. Martin, as a member of the sub-committee, said he endorsed every word which had fallen from the President. Everybody who had had to do with examining qualified men for professions had felt the difficulty of those examinations; it was almost impossible to differentiate the trained man from the man who was merely prepared for the examination. Training really was of the highest importance, and examination was really of relatively small importance. Probably all would agree that education was the keystone to examination, and that was the reason for associating the teaching element with the Board of Examiners, and in so doing they were forwarding the interests of those who were examined as well as the future of pharmacy. He regretted that any other note had been sounded, and he thought Mr. Atkins scarcely saw the full bearing of his observations. It was impossible that there should be any suspicion as to the fairness of the Board, and he did not like the suggestion that such a thing could possibly exist, and he should be glad to see a suggestion as to what Mr. Sandford would have said, he would remind him that Professor Bentley as a member of the Board of Examiners.

Mr. Hampson, interrupting, said the illustration did not at all apply.

Mr. Martin, in the if they were to have teachers as examiners at all, surely those who taught chemistry or botany in connection with pharmacy were the most competent men. With regard to collateral schools he trusted that some day schools would be established throughout the kingdom on the same basis as that in Bloomsbury Square, and then the area from which to draw examiners would not be quite so restricted as at present. It was of the utmost importance that those most competent, and who were above all suspicion, should form part of the Board.

Mr. Allen said it seemed to him that all the important work carried on by the Council nothing was more important than the appointment of examiners. They were on the eve of a new departure, and he should not have spoken but for a feeling to which he had given expression the previous evening that there was possibly a little unwisdom in appointing a member of their own school. He was bound to do that, thinking it over, he came hesitatingly to the conclusion that the best thing he could do was to support the committee on this point. He knew enough of the business of life to be quite sure that there would be some at least who would question this policy. It was not so generally known as was, perhaps, assumed by those who were familiar with the whole aspect of the question, that in the School of Pharmacy the Society had no particle of interest in the ordinary commercial sense of the word. During the whole period of its existence the members of the Pharmaceutical Society, aided and directed by the Council, had been putting their hands into their pockets to train men in what was called ideal pharmacy, to an extent of which the success of the past and the prominence of the present pupils afforded a sufficient guarantee. The point he wished to make was that as councillors, although they might have a parental interest in the school, they had no pecuniary interest in it; they had simply to decide what they considered to be in the best interest of the future of pharmacy. He had been thinking over the matter a long time, and had recently had the opportunity of consulting one or two gentlemen as able to judge of it as any men in London: and having quizzed one of these gentlemen in particular, his answer was that he hesitatingly thought the proper course was to elect one of their own professors. He made a mental note of that, and determined, if ever the subject came up, to adopt the course suggested to him.

Mr. Martindale said it had become almost an aphorism that a teacher made the best examiner; but in making this new departure and appointing teachers, which was agreed on some time ago, the question came up whether the teachers in their own school should be eligible. He fully endorsed the recommendation of the committee on that point, because it would be a great advantage to have the Board of Examiners in touch with the School, and to have continuity and permanence of policy on the Board. He was quite sure the gentleman chosen on this occasion would be above all suspicion. He agreed with Mr. Martin that training was the main thing to be looked to, but the question now before them was simply how the examinations could be most satisfactorily conducted, and from that point of view he heartily concurred with the committee.
Mr. Harrison said he was glad to think there could be no possible difference of opinion as to the personal merit of the gentlemen whose names had been submitted, and that they were all agreed also, he believed, that a teacher was the best examiner, but he did not think that the fact that the best examiner was the best examiner of his own pupils. He quite admitted that if it were simply a question of ascertaining the proficiency of a candidate, no one would have a better opportunity of doing that than the man who had taught the pupil; but the examiner should not be allowed to have any professional advantage. Nevertheless, it was an essential part of a man's legal qualification to practise his calling, and those results ought to be proclaimed by men whose position was altogether above suspicion; the decision must carry confidence outside. He agreed with the introduction of the teaching element, but with reference to appointing their own professors he was not quite so clear. The matter had come upon him rather suddenly, and he should not challenge the decision because it was evidently an experiment, and he preferred to wait and see how it turned out. The appointments were only made for one year or he should certainly have objected, for he could not be forward to the result with some anxiety. If his fears proved groundless, they could go on in the same course, but if it turned out that there was some ground for them they could retrace their steps next year.

Mr. Hills, as a member of the sub-committee, said he was thoroughly in accord, not only with the motion, but with almost every word uttered by the President, and he rather regretted that Mr. Hampson, Mr. Atkins, and others had spoken rather adversely, though they did not intend to oppose the motion. Mr. Atkins had, perhaps, expressed opinions which might he held by others outside, but he had been ably answered by Mr. Allen, who had apparently at one time held similar views, and had been logical enough to see his way through the objections. Of course, as Mr. Harrison said, they had to learn by experience, and how could they learn whether this was a wise course unless they tried it? It had been agreed by the Council some time ago that teachers should be placed on the Board, and then a sub-committee was appointed which had to select the four best men—two for chemistry and two for botany. In making that selection the sub-committee felt that no better result would be obtained than Professor Green, though he happened to be their own professor; he had been chosen as such professor on account of his high qualifications, and subsequent experience had fully justified his appointment. The Committee, therefore, thought he would make the best examiner, and from the reports of the last speaker, that the members of the Council came there to express their own opinions, and he should not respect that body at all if they were simply to adopt everything suggested either by the President or by the Committee.

The President remarked that there was nothing to which he was more disposed. He would remind members of the Council that they were exercising judicial functions and appointing a judicial body, and the merits of judges on the bench were not usually canvassed in public before they were set to work. He feared some of the observations now made might be a little misconstrued outside. At the same time, he did not in the least object to the matter being discussed. With regard to the suddenness of the motion, they must remember that most of them were non-resident in London, and that sometimes the business of the Society had to be done in twenty-four hours. He hoped that Mr. Atkins and Mr. Harrison would read the report to which he had referred some time ago, and as well as in articles in the Nineteenth Century, his statement absolutely born out that the best examiner was the man who examined his own pupils. He had satisfied himself also that every other qualifying body in London was doing that at the present moment. Yet objection was made they parted company with the departure. But if all other examining bodies—medical practitioners, veterinary surgeons, dentists, and so on—had their examinations conducted by their professors, the Council would be only following a precedent. With regard to their own examinations, he might explain that no examiner passed a candidate singly and without consultation with his colleagues; and he asked was it likely the sub-committee would select anyone who could not be trusted to act conscientiously and without suspicion? Those objections were absolutely in the air, and no doubt would be brought forward by candidates who objected, but he did not feel much anxiety. He believed the experiment would work well, but if it did not succeed the Council could undo it, though they would not take such a course simply on account of clamour outside on a fictitious basis. Mr. Atkins had evidently not read the latest publications with regard to the relation of teaching to examinations, and his views were those which prevailed some thirty years ago. Examinations ought to be conducted under the most favourable conditions to the unfortunate candidates—for they were all more or less nervous—and in order to ascertain whether they had acquired any elementary knowledge of the subject. That was where the judicial functions of the Board came in, more particularly when there was a conference between members as to the merits of a particular man, and whether he should pass or not. It was a reductio ad absurdum to suppose that one gentleman who would have only one-seventh in deciding on an examination whether a candidate should be put on the Register would really affect the result. Even if a man were disposed to prostitute his position by favouritism on the one hand or vindictiveness on the other he could not do so without the assistance of six other examiners.

Mr. Atkins said there was no suggestion of any such possibility. In his own case he merely wished to safeguard himself from the slightest personal references.

The President said Mr. Atkins' argument went in that direction. Whether the examiner were Professor Green or anyone else the same principle would apply; he would not be likely to act unjustly, nor would he do so if he wished, without the assistance of his colleagues. From his experience he was sorry to say that students from the Society's school were often, unconsciously no doubt, subjected to a more searching examination than those from other places. The School of Pharmacy occupied a good position, it was honoured amidst severe and intimate, he thought, the Committee had acted wisely in recommending the appointment of one of its professors. When in course of time Professor Green retired, or at any other time, he hoped their professors would always be considered eligible, and in his opinion it would be highly desirable that one or more of them should have a seat on the Board of Examiners.

Mr. Martin pointed out that the members of the sub-committee had held a great number of meetings, and their opinion was unanimous.

The motion was then agreed to.
The following gentlemen were, in accordance with the above resolution and with a recommendation from the Executive of the North British Branch, appointed Examiners for 1886:—

**England and Wales.**

Professor J. R. Green, Sc.D., M.A., Professor of Botany in the Society's School; Mr. A. C. Seward, M.A., Botany in the University of Cambridge, and Examiner in the University of Tripos; Professor Percy Frankland, F.R.S., Professor of Chemistry, Mason's College, Birmingham; Professor McLeod, F.R.S., Professor of Chemistry at Cooper's Hill College; Messrs. G. C. Bruce and A. W. Gerrard, W. M. Holmes, F. Ransom, J. E. Saul, W. H. Symons, B. White, and A. E. Tanner.

**Scotland.**

Professor Patrick Geddes, Professor of Botany in University College, Dundee; Dr. John Gibson, Professor of Chemistry in Heriot Watt College, Edinburgh; Messrs. Peter Boa, David Brown Dott, and Jonathan Innes Fraser, Edinburgh; James Jack, Arbrot, Thomas Mabon, Hawick, and John William Sutherland, Duddingston.

The President then moved a vote of thanks to the Boards of Examiners for their services during the past year, especially mentioning the retiring members, some of whom were not disqualified by age might again take their seats on the Board.

The motion was unanimously seconded.

The legal portion of the report of the General Purposes Committee was then adopted, and a special resolution passed authorising the Registrar to take proceedings against the persons named therein.

**January Council Meeting.**

The President announced that the January meeting of the Council would be held on the second Wednesday of the month.

**RECEPTION AND CONVERSAZIONE AT EDINBURGH.**

In connection with the opening of the new hall and laboratories at Edinburgh a reception and conversations were held in the Society's House, 36, York Place, on Friday, November 30.

There were about 350 ladies and gentlemen present, and the various were received in the new Examination Hall by the President (Mr. M. Carteigh and Mrs. Carteigh, the treasurer (Mr. R. Hampson), the chairman of the Executive (Mr. J. Laidlaw Ewing) and Mrs. Ewing, and the following members of the Council:—Mr. Martin, Newcastle (with whom was Mrs. Martin); Mr. Martindale, London; Mr. Walter Hilla, London; Mr. Eymer Young, Warrington; Mr. J. Johnston, Aberdeen; and Mr. D. Storrar, Kirkcaldy. In addition to most of the distinguished guests who attended the dinner of Scottish pharmacists on the previous evening (see report on page 489) there were also present:—Dr. Clouston, President, Edinburgh and Midlothian Society; Dr. Bruce Goff, President, Faculty of Physicians and Surgeons, Glasgow; Bailie J. Gulland, J.P., and Miss Gulland; Councillor J. P. Gibson and Mrs. Gibson, Mr. David Lewis, Treasurer of Heriot's Hospital; Mr. T. B. Morison, Advocate, etc.

After the reception the company were entertained to a programme of instrumental music by Dunn and Davidson's string band, while vocal music was admirably supplied by Miss Grace Richardson, and Messrs. J. T. and W. Richardson and Mr. J. H. Kennedy, the glee singing being especially admired.

* Illustrated descriptions of the new buildings were published in last week's Journal, where, however, the illustrations of the two laboratories were accidentally transposed.

In the dispensing and chemical laboratories were the following exhibits:—

**IN THE CHEMICAL LABORATORY.**

Plants from the Royal Botanic Garden, sent by the Regius-keeper—Professor J. Bayley Balfour, including—

Ipsecanuha Plant, in flower; with specimens of crystallised emetine hydrochloride, crystallised cepharine and its hydrochloride, from Dr. Paul Jaborandi Plant, in flower.

Red Cinerea Plant. Coton Plant. Tea Plant.

Coffee Plant. Strophanthus Plant. Inseivorous Plants.

*Pepenthes dicksonian.* Pitcher Plant.

*Saraecnia purpurea.* Trumpet Plant.

Saranca variolari. Spotted Trumpet Plant.

*Darlingtonia californica.* Side Saddle Flower.

*Drosera spathulata.* New Zealand Sundew.

*Drosca capsens.* Cape Sundew.

*Pinguicula specimen.* The Butterwort.

*Dionea muscipula.* Venus's Fly-trap.

*Cephalus folicularis.* Australian Pitcher Plant.

Photographs of Aristolochia pipas in flower.

*Droscon buiscudus.* Australian Flycatcher.

Exhibited by W. Hume, Lothian Street.

Hand Dynamo and Lamp.

Air Pump, Magdeburg Hemispheres, etc.

Manometic Flames. Singing Water Hammer.

Gless Model Fire Engine. Pulse Glass.

Atiken's Konoscope. Siren.

**IN THE DISPENSING LABORATORY.**

A series of interesting Microscopic Slides. Illustrations of Chinese Art Colouring.

Chinese Materia Medica, in four volumes, illustrated.

Various Exhibits, kindly lent by Dr. Paul and Mr. E. M. Holmes, F.L.S., etc.

These were arranged by Messrs. C. F. Henry and J. A. Forrest, Divisional Secretaries; assisted by Mr. W. B. Cowie.

During the interval in the musical programme Mr. Carteigh mounted the platform and referred to the excellent new arrangements which had been made for carrying on the Society's educational work. He said he was sure that it would be acknowledged that their new hall would be a credit to the other institutions of Edinburgh. The buildings were a source of personal gratification to himself because ten years ago he had advocated the acquisition of the present site, although some of his Scottish brethren looked upon that at the time as one of his misdeeds. He claimed for London that they had not forgotten Edinburgh, and it was due to his colleagues that he should say, and he was sure those present would acknowledge it that they had not been parsimonious in dealing with this matter. They recognised that they must have all the necessary appliances in order to carry out the examinations under the Pharmacy Act. They considered also that in Edinburgh pharmacy should be well represented, whether they benefited in a pecuniary sense or not. He hoped they would not misunderstand him. He was not begging. He was one of those who considered it a benefit to belong to the Society. If any chemist present had not yet joined them, if he would do so he would find they were not a bad sort of people. It was to the direct interest of chemists and druggists that they should belong to the Society. They in Scotland were logical enough to understand that. No doubt they had much to contend against, but he believed in the personal equipment of the individual, and if one made a living it was all they might expect in these days.

In regard to the buildings he highly recommended
good taste and judgment of Mr. Ewing, and he was glad to convey to him the congratulations of himself and his colleagues on the completion of their work. He also had pleasure in conveying these congratulations to Mr. Ewing’s colleagues. They had provided a charmingly decorated series of rooms at a minimum of cost. He congratulated also his excellent officer Mr. J. Rutherford Hill. He, Mr. Carteighe, had been associated with him ever since he became the assistant secretary to the company, and he was proud of the industry, patience, tact, and the goodwill he showed to everyone were known to all, and it was due to his self-denying exertions also that the new buildings had been such a success. In conclusion, he called for three hearty cheers for Mr. Ewing. The cheers, led off by Mr. Carteighe, were cordially given.

Mr. Ewing, in responding, deprecated the praise which Mr. Carteighe had bestowed upon them. They were much indebted, he said, to Mr. Carteighe himself for the generous interest he had always shown in the progress and completion of the buildings, and also to the whole Council. They were much indebted also to Mr. Stephenson, Mr. Neibit, and Mr. Hill, who, as a sub-committee, had practically arranged the laboratories in such a creditable manner as to make, he believed, their London friends somewhat envious. He was sure that they were all glad to have Mr. Carteighe with them on that occasion, and along with him, Mrs. Carteighe. Mr. Carteighe was the “Bismarck” of pharmacy.

Mr. Ewing concluded by calling for three cheers for Mr. and Mrs. Carteighe, and these were heartily given.

The musical programme was then resumed.

During the evening light refreshments were served in the Museum and in the Board Room by Mr. David Grant.

The departure of the President was the signal for a lively demonstration, the staircases and entrance hall being lined by ladies and gentlemen, who cheered enthusiastically as the President and Mrs. Carteighe passed out. Mr. Brenridge, the secretary, also received a very hearty parting ovation.

The Society’s house was effectively decorated by plants lent by Mr. James Buchanan, Oswald House. A very pleasant evening concluded about 11 p.m.

Proceedings of Societies in London.

CHEMISTS’ ASSISTANTS’ ASSOCIATION.

A meeting of this Association was held on Thursday, November 22, the President, Mr. R. H. Jones, in the chair. After the usual formal business had been transacted, a paper was given, the substance of which is as follows:

**Surgical Dressings.**

BY EDMUND WHITE, B.S.,
Pharmacist to St. Thomas’s Hospital.

Surgical dressings consist of materials treated in a special manner, so as effectively to absorb the discharges from wounds caused by accident or surgical interference. These materials may be in the form of gauze, tissue, wool, etc., and the substances generally used are cotton, wool, paper pulp, etc.

Two methods of dressing wounds are in use—the aseptic and antiseptic methods. The first consists in totally excluding all germs from the cut surfaces, and thus it is necessary that everything which may come in contact with the wound, such as instruments, dressings, etc., should be sterilised, i.e., rendered free from living germs. In order to render the dressings sterile, the following method may be used:—The wool, etc., as required by the surgeon, is placed in a glass jar provided with a lid, and the glass vessel with the lid beside it is placed in the steriliser and subjected to a high temperature for some time, during which all the germs are killed. The steriliser is then opened, a pad of sterilised wool placed over the mouth of the jar, the lid placed in position, and the whole sealed. In this form it is sent to the surgeon ready for use, and is not touched afterwards by the hand or any instrument not previously rendered aseptic. The steriliser used (see *Ph. J.*, ante, p. 191) consists of an iron chamber into which superheated steam can be blown, and is fitted with the usual safety-valve, pressure gauge, etc.

The antiseptic treatment consists in impregnating the dressing with an antiseptic—mercuric oxide, carbolic acid, the double cyanide of mercury and zinc, or sal volatile and boric acid being those most commonly employed. This treatment depends on killing any germs present, or which might have access to the wound after dressing. Gauze is extensively used on account of its open mesh and a liability to absorb discharges without sticking. The gauze impregnated with double cyanide of mercury and zinc is much used, the carbolic gauze stiffened by resin being valued possibly as much for its stiffness as for its antiseptic power.

Bandages may be made of muslin (which should bear without the cross fibres coming out), flannelette, or flannel. Linen (mostly cotton lin) is chiefly used for applying lotions, ointments, etc., to wounds. Absorbent cotton wool is used—as the name implies—to absorb discharges, etc. The absorbent power varies in different specimens, being due to the thoroughness, or otherwise, of the method by which the fat has been extracted. Very highly absorbent wool, however, may absorb so quickly as to form a stiff lump just over the wound. In place of marine sponges, which are cleansed only with great difficulty, so-called sponges of cotton-wool have been largely used for absorbing liquids in cavities, etc., and are used either in a aseptic or antiseptic condition. They are impregnated with pieces of wool held together in the form of a ball by gauze, and on account of their cheapness can be thrown away after use.

Wood wool, consisting of woody fibre finely disintegrated, is used as a dressing for wounds. It is often used between soot of gauze, forming a tissue and makes a firmer dressing than cotton wool. Paper pulp is also used in place of cotton wool, and forms a very light and airy dressing; in addition to this it is very absorbent, and is usually used aseptically.

Ligature and suture materials may also be used aseptically or antiseptically. When cautery is used, sterilisation by heat cannot be used: it is usually first soaked in a solution of mercurio chloride or other antiseptic for a week, and then kept in absolute alcohol. Silk, silver wire, silk-worm gut, salmon gut, and kangaroo tendon are also employed, and they are sterilised generally by heat or by special methods.

Various materials are used when necessary to protect dressings from evaporation or from soiling the clothing. Gutta percha is largely used, and besides easily adapts itself to irregularities in the surface to be covered. Jacocet—a muslin, waterproofed on one side—oiled paper and oiled silk are also used.

Mr. White described several methods of wound-dressing, and passed specimens round for inspection by the audience. A bandage was also shown, composed of strips fastened in the middle and loose at each end, which was used in certain abdominal operations.
Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

A meeting of this Association was held on Wednesday, November 28, the chair being occupied by the Vice-President, Mr. John Foster, in the absence of the President of the Association, Mr. W. L. Currie, through illness. Amongst those present were Mr. Carteghe, President of the Pharmaceutical Society, Mr. Carteghe, Mr. M. L. Currie, Mr. T. W. W. M., Registrar of the Pharmaceutical Society, and the leading chemists and druggists of Glasgow and the West of Scotland.

The Chairman, in opening the proceedings, said he felt a very high honour had been conferred on the Glasgow and West of Scotland Pharmaceutical Association by Mr. Carteghe so kindly coming to address them. His only regret was that their own energetic president was still unable to be with them. He was sure they would join with him in according a very cordial welcome to Mr. Carteghe, and was certain they would have from him words of wisdom, warning, and comfort, added, words of encouragement. He was hopeful that much good might accrue to both the Pharmaceutical Society and their own Association from this visit. In Glasgow they had opportunities of making the work of the Society better known to the public, and of trying to get those who still remained aloof from the Society to come within its pale and help in its great work. They also had opportunities of assisting the widows and the orphans of those who had been less fortunate than themselves, and he regretted to say that in Glasgow they subscribed very meagrely towards that object. Further, they had the responsibility of endeavouring to provide for their assistants and apprentices that pharmaceutical education which the law made imperative they should possess before they could be of much service to their employer or earn a living for themselves. He hoped, therefore, that much good would result from this visit. In Mr. Carteghe they had a strong man and an experienced head, one who, if backed up by the united voice and sympathy of the trade, would yet by his consistent and persevering efforts help the little barque of pharmacy into a quieter and better haven than it had been in for a long time.

Mr. Carteghe, in his absence, had formulated some of his views and opinions in writing, and his secretary, to read the meeting, in the hope that they might serve as an outline to Mr. Carteghe’s speech. Mr. Lasing, before proceeding to read Mr. Currie’s paper, said they would be glad to hear that Mr. Currie was feeling a little better. In a letter written to him he expressed a regret at being unable to be present, and said he hoped the meeting would be a very successful one, and that Mr. Carteghe would have a royal reception and a good hearing.

Mr. Currie’s communication was as follows:

“We in Glasgow seem to be so much more at a disadvantage in our business in comparison with other places, that we are disposed to think the powers that be—that is, the Council of the Pharmaceutical Society—should do a little more towards putting things on a better footing.

“We have had it stated that pharmacy as a trade is not worth the trouble of being made an act. It is a greater failure, and what guarantee has anyone entering our ranks that, after undergoing the requisite training and study necessary to obtain the title Chemist and Druggist, or Pharmaceutical Chemist, that the said title will be his, protected by Act of Parliament. To make it professional, we have not attained to such perfection as to entitle us to receive that protection which our education and training fit us for. Beyond the personal selling of poisons, any one can dispense drugs. But even the sale of poisons and the use of the title is, by a little ingenuity, glaringly infringed. We know that grocers and others by the simple addition of the magical ‘and Co., Limited,’ to the title, as in the Act, and the word dispensing chemists. This is not as it should be; the title is a personal one, and should not be conveyed in such a way to any company, and, with all deference to the wisdom of Bloomsbury Square, I am of opinion that, should John Jones, a grocer, as an individual, convert himself into a pharmaceutical chemist, have the right to style himself ‘and Co., Limited, dispensing chemists.’ What is the use of passing examinations in order to obtain the title if it can be used by any huckster in this fashion?

“We cannot expect to get smart youths to enter our calling when we put the true state of affairs before them, and it is not to be wondered at. I certainly say let us have well educated and trained men as pharmacists, but if the education is to take the form of a compulsory curriculum, then some better measure of protection than we have now must be thought out.

“As regards the sale of poisons, it is distinctly stated in the 17th section of the Act, that the name and address of the seller should be on every label, and for the purposes of this section the person on whose behalf the sale is made shall be deemed the seller, and I have always understood this to mean that, allowing such poison has been obtained at any limited company’s stores, the name of the qualified chemist should appear on the label. Why, therefore, can poisons be sold with the name of a company and not the name of a qualified individual?

“In regard to the work of the Pharmaceutical Society much has been and will yet be said. The cry has always been, What good will result from joining it, and many objections have been urged against it. One great objection has been that, although one may be a registered man, if not in business on his own account he can have no voice in the conduct of its affairs even though an associate. It should follow that, having passed the necessary examinations, he should, immediately on joining the Society, have a voice in its affairs, whether in business for himself or not, and I admit that in the last two Draft Bills the Council seemed desirous of making this change, but the fault has been long in being remedied.

“The appointments of profesorial teachers as examiners in scientific subjects deserves, I think, commendation, and ought to do away with the often expressed idea of unfair examination. I think I have sufficiently indicated some of the points Mr. Carteghe could very well enlarge upon, and while it is always a disadvantage to have to write one’s views from a distance, I hope I have helped to forward a meeting to which I have looked forward with much desire, thus in some degree making up for my enforced absence.”

Mr. Carteghe, who next addressed the meeting, said: Let me in the first place say that it is a source of very great pleasure to me to have the opportunity of meeting you as representing collectively a definite pharmaceutical body. The last time I appeared here I had to address a meeting Limited, I don’t quite know whether it consisted of chemists or druggists, of doctors or doctors’ assistants not registered, or what; but I understand I am now addressing an association, and I am sorry that Mr. Currie, your indefatigable president, is not here to-night to take the chair. I am sorry because I have noticed with what interest he has thrown himself into the work of pharmacy in Glasgow. As your vice-president says, it is a slight reflection upon you that you have not been able to emandep
yourselves completely for so many years, and form an organisation of your own. I do not mean to say there may not have been good reasons—I do not mean to say anything more than that there are probably good reasons for it—but the fact remains that of all the great cities of Great Britain, Glasgow, until within recent years, has not taken any active part in things pharmaceutical, and that is a disadvantage to Glasgow, it is a disadvantage to the Pharmaceutical Society of Great Britain, and it is a disadvantage to its President. On the other hand the formation of an association of this sort, with plenty of the backbone that all you Soothsayers have, is a source of strength to us, even if from time to time you gibe at the President, or differ from him in some matters of detail.

Let me say that I have listened with pleasure to Mr. Currie's observations, and perhaps I may be allowed to say a few words as preliminary before I touch upon the special part of his paper. I am anxious just hurriedly to point out to you the history of pharmacy legislation. That is probably an old story, and if any of you have heard it before, I hope you will forgive me, but it is an important story, and, as every year we have fresh men on the Register, I think it is well that they should know exactly how we stand. Now in 1852 an attempt was made to get a Bill through Parliament by Jacob Bell; we in these days would have called it a Pharmacy Bill. It had nothing to do with poisons, but dealt with the great question of educating and training the pupil how to dispense prescriptions whether containing poisons or not. The idea at that time was that if a man had been educated he did not want the State to tell him to label bottles containing poisons, nor did he want all those safeguards of a mechanical kind which the Legislature is so anxious to put upon us if we will only allow it. Mr. Bell failed in getting any compulsory powers, and although he went to Parliament and spent in the space of a few years something like £15,000 on matters pharmaceutical and political in the interest of the trade at large—I wish to point out that out to you, for the benefit of the trade at large—he was unsuccessful in getting the House to assent to anything more than a voluntary regulation by which certain people who choose to do certain things should become "pharmaceutical chemists." That left everybody else pretty much where they were. On and after that date no person engaged in pharmacy could call himself a pharmaceutical chemist unless he joined the Society and passed an examination, and I want to point out to you that it was open to everybody in the United Kingdom to become in 1852 and 1853 a pharmaceutical chemist, and scarcely—what shall I say?—scarcely a tithe of them took advantage of it. Bell's view, after the passing of the Act, was that if we could get all the men engaged in business in Great Britain to come into the Society we should have something to work for, and they could push a step further later on. I do not want to rebuke anyone; that is a matter of history.

The next stage was in 1868, when I was myself upon the scene, and I know the history of pharmacy legislation from 1865 as well as most living men. During that time I have been scoffed at and jeered and scalped, but still I am alive, gentlemen. In 1866—and I was then on the Council under the leadership of George Sandford, the worthy successor of Bell—we attempted to get through Parliament a Bill on the same lines as the Bill that Bell tried to get through in 1852; that is to say, all persons then engaged in business, and all assistants then bound fide engaged in business should not only be brought into the Society, but be registered, and that the right to dispense all prescriptions of whatever kind should be restricted to those persons, and to no others except those who should hereafter pass through a certain amount of training and examination. You will observe there was no question about poisons. We accepted a semi-professional basis again, that the education of the chemist and druggist was the safest thing for the public. Mechanical things are after all only mechanical, and our view was that the educated chemist and druggist, if left to his own discretion, was surely competent to take care of the lives of the public.

Concurrently with our pressing a Bill of this sort, a society called the United Society of Chemists and Druggists was brought together by a Mr. Buott, who was the active organiser. This man thought we were making a great mistake if we wanted to make the trade, as it was called, a close profession, and accused us of interfering with free trade, and he conceived the notion of getting a number of people to join him. Now, mark you, those were chemists and druggists who were saying, "You are going to interfere with free trade." They replied, "Oh, no. We don't want anything of the kind. We want freedom of trade on the one hand, and we want restrictions on the sale of poisons on the other, and we think that is enough for the drug trade at the present moment." They carried out their views by submitting to Parliament in the year 1866 a Bill which was simply a Poisons Bill. These two Bills—the one promoted by my Council and the Bill promoted by the Committee of the United Society of Chemists and Druggists—were referred to a Select Committee in Parliament. A lot of evidence was taken of the squabbles between the Pharmaceutical Society, on the one hand and the United Society of Chemists and Druggists on the other, and their differences were so striking, that the Committee of the House of Commons, as you could well understand, felt rather sick of the whole business, and did not know exactly how to get out of it. They got out of it by saying they had taken evidence, and were of opinion that there should be legislation on the sale of poisons. That is as far as we went.

Now I want you gentlemen to notice that in these unfortunate circumstances, although we on the Council of the Society had offered membership of the Society in its entirety, to every person engaged in business, and various other things of the kind, there was still this objection on the part of the trade at large, to our going to Parliament for what they called
interference with free trade in their business. We did not propose to interfere with free trade at all. We proposed to register every person in the trade, and every assistant when he became of age at twenty-one, and we went so far in our liberality as to say that even registered apprentices had a sort of vested interest in our trade and we would register them. We were opposed, gentlemen. We were supposed to have something up our sleeves. We were not considered capable of taking a broad view of the life of the chemists and druggists throughout the country. We were supposed to be a few West-end of London people living in the lap of luxury, and having no sympathy with the chemist and druggist. You know, gentlemen, that I am a working chemist and druggist as well as yourselves, and there never was at any time, nor can there ever be, any difference between one registered man and the other. We are all affected by whatever takes place in legislation, and it is absurd to talk of what is good for one man not being good for another. Well, gentlemen, we were met by this difficulty of free trade. The notion was that we were going to convert what had been the good old-fashioned business of chemist and druggist into something that was new-fashioned and a little professional, and that we were going to do harm. Some of this bitterness arose no doubt from the fact of the great difficulty in arranging on what terms the chemists and druggists in business should come into the Society. There was a little ill-feeling engendered by the fact that, on the one hand, certain men who had passed the Major examination and had got the title were not disposed to give up that title to everybody else, and, on the other hand, there was a disposition on the part of some, including myself and others, to deal broadly and as we thought loyally with everyone who was engaged in business. However, that was the result. The opposition practically defeated the principle for which the Council of the Pharmaceutical Society had gone to Parliament, because they simply said, "We only want poisons dealt with."

Well, Mr. Sandford, with very great courage, admitting the difficulties of the situation, thought it better to take half a loaf than no bread, and he set to work with the Council to draft a Bill to try to come to terms with the United Society of Chemists and Druggists as to what we could agree upon and go to Parliament with them. In the course of 1867 we came to terms, and in 1868 we went to Parliament, and the present Bill, with one important difference, represents really what the original Bill was. The difference was that our Bill, before it became law, provided in the most generous way for the rights of everybody connected with the trade in its widest sense, including apprentices. But when we got into Parliament the Privy Council came upon the scene as representing the Government, and said—"No, no; nobody under twenty-one may pass the examination; that is necessary for the safety of the public." So there was this objection to assistants who were not in business at the time of the passing of the Act, and for a long time we had a difficulty in getting the Privy Council to agree to what is known as the modified examination for those men. But the Pharmaceutical Society, I consider, did not, on the whole, deal with the trade unjustly or unfairly with regard to these educational matters. It is right that apprentices and right that assistants should be registered. And, having once come to that conclusion, and having finally, when the Bill did pass, registered everybody in the kingdom for nothing—a piece of generosity which I venture to say no other corporate body ever did in the course of its existence—I think I may claim that the Pharmaceutical Society has never been very hard on the trade. That is practically the history of the present Act.

Now this brings me to refer to the defects of the Act. What are the defects of it? In the first place a serious defect is, it does not provide for a trained apprenticeship, the training of the pupil before he goes up for examination. And when I say that, I mean it seriously. I mean it is a disadvantage to the youth who goes up for the examination that he has not been given a proper pupillage or apprenticeship and gone through a short course of training. I say not only is it a positive disadvantage to him, but I conceive that a chemist and druggist in business, whether only three or four-and-twenty or four-and-seventy, is damaged in his personal relations and in his pocket by having men coming into his craft on the result of a mere "oram" examination. That is what I say. The engineers in this great city of Glasgow, shipwrights, and others, never admit anybody into their body before he has passed through a long course of apprenticeship. They produce a skilled man; and they do not say, "We want to put a restriction upon the trade, not because we have an objection to compete with men who are capable, but we object to compete with men who are not capable; these are the men who do bad work and bring our trade into disrepute." And so in pharmacy. Those are the people who are likely to be led away by mere trade considerations. And so I prefer proper training. I think it is politic, and a safeguard for ourselves and the birthright of the pupil. I think that it is cruel for any of us to take a pupil and make use of him—to take him, for instance, as I am told is sometimes the case, more as an errand boy than as an apprentice, to use him for ordinary work which can be performed by anybody—and then after two or three years suggest that, for a consideration, or rather a reduced payment in weekly or other stipend, he shall prepare himself for becoming a chemist and druggist. I know such cases in this city and in a great many other cities. I know a good deal, of course; I see examination papers, and I see statistics, because these unfortunate people, lost, benighted as they are, have been weak enough to get me to preside over the Board of Examiners for many years. I am afraid I have got to know more than I ought to know, and I do know this, that some of my weaker brethren—I do not use the word in any unkind sense; I mean to say those who have not the backbone I should like to see in every chemist and druggist—
who are thinking of their balance from morning to
night, counting their shillings and wondering if they
can open their pharmacy to-morrow, are often suffer-
ing from a species of nightmare.

I know of nothing more capable of making a
man miserable than for a chemist and druggist
to try the daily process of considering exactly
where he is. Well, I say that for the man who is
doing a comparatively small business, struggling for
an existence and wanting some assistance, there is, no
doubt, a strong temptation for him to take that which
will cost him least money. But I want to put it to
you, if he does that he is preparing for himself a little
rod which in a few years may be the means of taking
away his own business from him. A man may, indeed,
get through the examination, but he won't have much
training. He won't have much sympathy; he adopts
the first profession which presents itself to him, and
he has not been educated before the age of fifteen or
sixteen for the work of his life, with the result that
he is a hermaphrodite. He is neither one thing
nor the other; and such persons are those who are least
scrupulous in their consideration for their brethren
who are brought up in the regular course of
trade. I justify proper training of apprentices
and future chemists and druggists on the ground
of advantage to the man himself—that is, the
pupil—and on the ground of pecuniary advantage
in the long run to every registered person.
For these reasons I think, therefore, it was a mistake
not to have provided for them. And when I say it was
a mistake, I may say that my friend, Mr. Sandford,
when alive, always had the impression that our powers
were sufficient for that purpose, and he contemplated
later on that a definite course of training would be im-
posed.

You will say, "There is no certificate required for
a three years' training; and how are you to get over
that?" I am sorry to say the clause of the Act is so
carelessly worded. I did not see it when it was
drawn up, therefore I am not responsible for it.
The Act does not give us legal power to impose
that particular form of training, nor does it give us
legal power to require anything more than the
broad statement that a man has been engaged for
during a certain number of years in the writing and
dispensing of prescriptions, and that is such a very vague
thing; it may be in a doctor's shop, it may be in an
infirmary, or in a closed surgery kept by a doctor, or
anywhere. I do not mean to say it is ridiculous, but I
mean that it is so worded that we have no power to
refuse a certificate of this kind for work done, whether
it is done in the pharmacy of a registered chemist
and druggist or not. My point is that a man
may be trained anywhere away from a chemist and
druggist, and if you only get a certificate to this
effect, we are bound to examine. And I am bound to
say that is absolutely worthless. The certificate issued
is worthless for the purposes of any evidence of
training. I should like to have that certificate
repealed. I should like to have every person producing a
certificate of at least three years' training with a
registered chemist and druggist. I do not consider that
a doctor has the means of teaching a pupil, and therefore
I think he should be with a registered chemist and druggist.
If a registered chemist and druggist has time when
dispensing in a public institution, I see no real reason
why he should not take his pupil there and teach him.
But it is perfectly absurd to suppose that there is
nothing in pharmacy at all. I hold there is a good
deal in it.

It is perfectly absurd to suppose that an ordi-

From the Pharmacetical Society's

in the world, including

and the whole thing is ridiculous in

and I am sorry to say that in Great

I submit to you that the skill

and knowledge required for the dispensing of prescrip-
tions containing things not in the Felsons Schedule
requires as much care for the safety of the
public as the dispensing of a dose of morphine
or opium, and that the whole thing is ridiculous in
its present form. I believe if we could only get a
hearing in the House of Commons on this subject we
should achieve our point in regard to that. I do not
think at the present we can go further than that, but I
do think that the compounding of medicines generally
—the putting together, in definite quantities, of
different things of more or less potency—is a thing
that ought to be—and every physician in London
and every educated man I have spoken to thinks it is
a thing that should be—restricted entirely to chemists
and druggists. I do not mean that doctors are to be
debarded, but I mean to say if it is right that the dis-
pensing of a mixture containing a tenth of a grain,

and I am not a strong politician of any sort, but I
confess that for many years I have advocated this.
I consider that it is a right thing, and,
what is more, I consider that we went wrong in 1888 when we did not make it so. It
may be some satisfaction to you to know we
actually so intended it to be. In the first instance,
when the Bill was drafted, the clause dealing with this
subject read—"That all persons after the passing of
this Act who are duly registered as chemists and
druggists, and who shall, hereafter pass the Minor
examination, shall be eligible to become members of the Pharmaceutical Society. But I am sorry to say that some of my examining friends of my own age were so strong in their opposition to this clause that we were obliged to give way. Parliament was about to be dissolved, our Bill was in the House, and you know how little opposition will sometimes kill a measure, and we were obliged to accept that very dangerous thing—often a very necessary thing all the same—a compromise. We had to say: "Very well; every chemist and druggist in business at the time of the passing of the Act shall be a member; there we will stop if you are content, and every Minor man shall be associated." You will observe, if you read that section carefully, we gave the Minor man as nearly as possible all the privileges of membership excepting the name. We gave him voting power, but he must be in business.

Well, that was a compromise, and I know it was much to the regret of Mr. Sandford that the clause was altered in this way. My only apology to you for having to explain it after so many years—twenty-five years afterwards—is this, that I had to deal with it at the time, when perhaps I was the only examined pharmacist on the Council. I was by far the youngest member on the Council. I was a kind of whip, and I found that the men about me who objected on this point were men of considerable influence. They were all of them well-wishers of the Society, and had a notion that when once it was necessary for a man to pass the Minor examination, he would, almost as a matter of course, go up for the Major. We had conceived the notion that every chemist and druggist would feel that he must in some way, as a matter of aspiration, go up for the Major, and in that way probably no great harm would be done. I tell you frankly we were all wrong, and Mr. Sandford perfectly right. I am one of the wrong-doers, because as a matter of expediency I was obliged to vote for this alteration, in order not to lose the Bill then in the House. Those of us who belonged to the young examined class at the time were disposed to sacrifice anything for the good of the trade, but it was impossible for us to compel our older brethren to do the same.

That is one excuse for what I consider to have been so far an imperfect bit of legislation as regards the constitution of the Society. And some excuse is probably to be allowed to us because there had been a great outcry, a great desire, that every person who was in business should be made a pharmaceutical chemist straightforward. There were many of us, including myself, who would not have objected to that, but there were difficulties, as all of you will see; and I think if any of you choose to think over what I have said so far, and consider the difficulties we had—an unsympathetic trade tacitly helping us but really thinking that we were playing the fool, crying all the while for free trade which might be taxed, poisons, and every sort of sundries and outside things, and caring little for what we chose to call pharmacy—I think you will see we were in a very difficult position.

And what do we find now? You will find that those men who opposed us are the persons who now cry out more and more for protection. And those are the persons who write to me, as your President, clamouring about the rights of protection, and who, I venture to think, would have been much worse off even in Glasgow—if there are any of them, and I dare-say there are—than they are now if that little bit of legislation had not been passed.

I say, defective as the Act is, it has prevented some of us from having been absolutely swept away in the fierce competition that is going on. Lastly, the Council has drafted Bills—Mr. Currie cleverly says that it is rather slow in moving. By the Council, I think he means, not the Council of this Association, but the one which I have the misfortune to represent here to-night. It is quite true, but so long as both Scotchmen and Englishmen will consent to allow the whole time of the House of Commons to be absorbed by questions affecting Ireland, what can be done? I say nothing about politics, but that is a broad fact. We have been told over and over again: "Ireland blocks the way" to private legislation; and Irishmen meanwhile can go in and get their Act, and get exactly what they want, including the compounding of prescriptions. But we in Great Britain are left out in the cold. Of course, if Mr. Currie wants this particular part of his work done as well as others, I think I shall be able to tell him presently that we must not only have an opportunity for getting what I call domestic work done in the House of Commons, but work that affects a large number of us very materially, and will be looked upon as much more important in the colonies than the question of the particular government of a particular neighbouring State under particular conditions.

When we get that chance I hope we shall be able to do something, and it is not our fault that we are under this condition of things, and that our little Bill gets pressed out; because, gentlemen, there are people interested in keeping things as they are. There are people engaged as chemists and druggists who do not believe in the Pharmacy Act of 1868, or any Pharmacy Act—who do not consider that it is right to be fettered or bothered by legislation of any sort, and, although on our Register, they are at heart directly hostile to any progress which will benefit the general class of chemists and druggists. Associated with those men are wholesale men who are equally interested indirectly in this sort of proceeding, and we have in our own ranks material opposition which, the moment the President of the Pharmaceutical Society gets into the House of Commons, is put before him with very strong and very cogent arguments. You have people who tell—indeed, they are on our Register—that it is all an absurdity, and that the best thing for the public would be free trade in drugs and medicines. I have at my back a motley group of men—an increasing number, I hope, in Glasgow—a comparatively small number in the whole of Scotland. I have at my back, as President of the Society, a very fair number of registered men in England, but out of that number I stand probably in the
position of having one-third behind my back, and two-thirds not within the fold. I mean behind my back are the men who can be trusted to support the President of the Council. What can I do in those circumstances? Whom do I represent? Do I represent the registered chemists and druggists of this country? Does my Council represent them? I do not. I point to a career of unselfish devotion to the interests of the public and of my craft. I show that we have not been sleeping, that we have encouraged education in the broadest sense; we have been liberal in all round and promoted education. We have done all these things, public acts which, in the eyes of the House of Commons, bring recognition of good work done. I bring all these things, and then comes this question, "You do not represent every chemist and druggist." That is not the fault of the Pharmaceutical Society, gentlemen.

Then the last defect as regards ordinary matters that I should like to see remedied in a new Bill would be the right to strike off from the Register persons who have been guilty of misconduct. You know what mean by misconduct. I mean serious misconduct and crime. It is an astonishing thing that we have not that power. I cannot understand why. The only power that is reserved for misconduct is a most curious one, but the clause was put in by the legal adviser of the Privy Council, and he took care, as we did not seem to want to strike them off for misconduct, that the Privy Council should have that power. I am bound to tell you we thought we ought to have that power, and we willingly assented to it; but we had a number of men almost opposing us, and who were only pressed into a kind of acquiescence. We aren't raise too many difficulties in regard to matters of this sort. But in the passage of the Bill through the House the Privy Council insisted that if a person failed to conform with the regulations in regard to the sale of poisons under the 17th section, it should be within the power of the Privy Council to strike him off the Register. So they took care that there was a power behind the Council of the Pharmaceutical Society to strike a man off. It does not apply to a person unregistered; but if a man went on selling poisons, he being registered and did not label his poison nor write up his poison book, and that thing went on for more than once or twice, then there is power to strike him off the Register. But for offences which we are much more likely to come across, and of which, it seems to me, all registered persons are bound to take cognisance, we have no power at all. But we are bound to have that power. I think you will agree that it is a right power. Not the power of going into little petty things, but, in a broad sense, misconduct of a certain kind is misconduct which we all understand, although indefinable in terms.

Then, Mr. Currie, your president refers to that great bugbear of the present time, a bugbear not only affecting us, but affecting every person engaged in retail business, namely, company trading. He says, and very rightly, that it seems an anomaly that seven persons, making themselves into a corporation by payment of a small sum of money, should be able to do what an individual cannot do; and, further, I am sorry to say he hits me very hard when he brings it up. Well, I am sorry to tell you that it is the fact that all corporate bodies are outside the Act. It is a fact, and it is the law. It is the law because it has been decided by the House of Lords, and it will be the law until it is altered by special enactment through both Houses of Parliament. It is no use crying. It is the law, and it is no good abusing the Society. The question is—Having got the law, can we alter that law, and if so, how are we to do it? I have from time to time referred—I think I referred to it the last time I was here—to the difficulties about the "Widows' Clause." I was one of those who in 1866, when the present Act was in draft, I was one of the few members of Council who opposed that "Widows' Clause." I hold that you cannot transfer the personal qualification of the individual to the widow or her children or a corporate body, or anybody else, and by having a clause of that sort you are simply throwing away your birthright. For you are personally qualified, or you are not. What was the answer? A defeat. For the whole Council, men double or treble my age, said, "This is a very inexperienced young man, and we must sit upon him. He wants pharmacy to be a profession."

That is what we hear going on now. I ventured to say then, as I say now, "I do not care what you call it; if you ask me to go through a course of training and be at certain expense to become qualified, it is hard lines to allow somebody else not qualified to be in the same position as I am." But it is asked, How is a man to dispose of his business? and, What is to become of the widows? I venture to say that that is an illogical and a contemptible argument. Of course, I do not use these words in a personal sense, but I think it is a weak argument to use that a person when he dies cannot—or rather his executors cannot—get a fair value for the business, and that it is therefore better for the widow and her children that this business should be carried on for her; that the realisation of the little business would bring, we will say, if sold, a small sum of money, but if carried on with care by some other person at a salary—which, as we are aware, in those days was not very high, and is not and not likely to be regarded as very high at any time—it would support the widow and the children being brought up. When a man talks about his widow and children he begins to play the fool—logic goes away at once. That is what happened here; and I and another gentleman, I believe, heard the reputation of being the two most hard-hearted persons that ever existed, and as we were both unmarried we were supposed to know nothing about the subject, and were sat upon accordingly. That was in camera and against the Bill. It was pointed out, and rightly pointed out, that the whole trade would be against us. It was true. The whole trade was in favour of that clause; there is a large part of the trade in favour of that clause now.
I believe the majority of the registered persons in business are so illogical at the present moment, that if a minister were to say to us, "Gentlemen, we see the danger to the public when a person dies that his business should be handed over to his widow or his executors, will you give it up?" I don't believe if I appealed to my brethren throughout the country I should get an affirmative answer from the majority. I don't believe I should, and at the same time those gentlemen wish us to check the companies. The law of company trading in regard to chemists and druggists is laid down in the decision of the House of Lords. A legal case was fought from one court through four courts, right up to the House of Lords, and the final decision was given on this account that we, the authors of the Bill, and Parliament as approving of the Bill, had held that, in the case of a widow, a registered person might carry on business, but nothing was said about corporations, and that if corporations got registered persons to carry on their business they did not see that the danger to the public was greater than if a widow, as owner of the business, carried it on. Now, gentlemen, are we so blind as not to be able to see that whatever we think of the judgment, there is something like reason even amongst the law lords who took that view. I think that "Widows' Clause" was the cause of our defeat in company trading—our own clause. The weakness—the want of masculine character—in the men who had charge of the affairs of 1868, coupled with the apathy of the trade at large, was the cause of our defeat. They would not do one thing or the other. They were free-traders in one thing, and yet they were for a certain sort of restriction, but the moment you said, "What is going to happen when you die?" away went logic and principle. "Let some one carry it on for us," they said.

That is the condition of things regarding company trading. My difficulty is to know what to do. I believe it may be possible to deal with certain forms of companies we are in the habit of calling bogus companies. I am not speaking of big organisations like what, I daresay, you have in Glasgow and we have in London, with a large number of regular shareholders, and so on. What we mean is a huckster or a man who calls himself a grocer, and does that which a chemist and druggist does, and who, when we, the Council of the Society, take proceedings against him, takes in his sisters, his cousins, and his aunts, to the number of seven, and makes himself a corporation. Apart from the question affecting us chemists and druggists it is, a scandal in any case. I do not hesitate to say there may be in the near future a chance of doing something in that particular direction in regard to the formation of such bogus companies, on the broad issue of how far we can persuade Parliament or the Privy Council that if we are to have our businesses carried on by our widows or our executors or trustees, it must be by registered persons. If we want that I say we cannot ask for the other, and if we ask we simply won't get it. That is the thing that a chemist and druggist has got to make up his mind about. His bread and butter are being taken away, and I sympathise with him deeply. It is a scandalous thing; but I do to some extent excuse the law, because the trade at large actually prepared the very thing which is now the instrument by which our own backs are being lashed, and we suffer accordingly. But what I cannot understand is this. You remember when I was last in Glasgow I had been talking about a draft Bill that was before the Council. I referred to it then and pointed out, as I do now, that I was sorry to say the great majority of our registered brethren will not have that "Widows' Clause" altered. Until you consent to have that "Widows' Clause" altered or dropped you cannot come with any logic to Parliament and ask it to make alterations in the company law.

I hope I have been plain enough, and I know you in Glasgow like straight speaking. That brings me to the question that was put by Mr. Currie as to the view that if this sort of company trading goes on there is no encouragement to impose a curriculum or apprenticeship upon a pupil. I wish to point out that two wrongs do not make a right. There is one feature of this subject which impresses me. That is that there is only one way, until we get fresh legislation, that we can deal with these companies. That is by the personal qualification of the individual who keeps his own pharmacy. I submit to you that if a man has had a decent training and you put him into a pharmacy in Glasgow, and he attends to it and shows his intelligence, his chances of getting an honourable living are immeasurably greater than if he had been trained in a doctor's shop, and then simply shot through an examination.

I need not say to you rich people in Glasgow that the whole difficulty we are suffering from retail business is from the fact that we have too much money. We have too much money in the country. We cannot get 1½ per cent. for our money in any ordinary bank or any other concern. Money is practically so plentiful, that it is not worth investing in the ordinary sense of the term; you might as well put it in a stock— I mean if you want to be quite sure of it. And the result is, banks and corporations and others whose business it is to collect money are ready to lend money for any purpose— retail trading, cattle trading, or any conceivable thing under the sun—and we in London have to compete with people who are being financed by getting the whole of their capital from the city banks at the present moment, because they do not know what to do with their money. They probably regard us as the weakest set of mortals going. And it is true. We cannot agree about many things; still, their hand is against everybody. And with this immense onslaught of capital against the individual, who is able to fight capital under such circumstances to best, the trained or the untrained man? I submit that the trained man at the present moment who attends to his own business is most likely to hold his own, if not to beat even large stores in the conduct of the business of pharmacy. And it is, therefore, wise for us to do as much as we can ourselves. If we cannot afford to take people as our pupils who have
the necessary education to pass the Preliminary and become decently trained chemists and druggists after on, let us do without them. Let us have a porter, an errand boy, or a woman. Let us stick to our own business; let us shut up our pharmacy and do as lawyers do, put up the notice "will be back at 10 o'clock." Let us make the people feel that we personally are wanted, and I venture to think, even in Glasgow, despite doctors' shops around you, you will be respected by everybody about you if you are able and willing to do that sort of thing.

In regard to examinations, we have shown by the appointment of scientific men as examiners that we are desirous that the examinations of the Society both in Edinburgh and London shall be of such a character, that the man who has learned his botany or chemistry anywhere can get an examination which will be least liable to the observation that the person who examined him in the subject is probably too well known in it, or too technical, or expects too much to appreciate what he knows. You know as well as I do that the difficulties in life in regard to examination depend very largely upon your being able to place yourself in the position of the student. I have been in the habit of saying from time to time that I believe the President of the Pharmaceutical Society could make it very inconvenient for any registered person at the present time to pass an examination in any one subject of the Schedule. I mean to say he could talk, and cross-examine, and sit upon the candidate, and in the process I think he could effectually "pluck" him. I say that for myself. Perhaps I have done that sort of thing in the course of my life. I may have done it. I have not done it knowingly, but I dare say I have. I plead guilty to the possibility of being as much a sinner as any person engaged in pharmacy who is not at the same time engaged in teaching chemistry and botany to students. It seems to me to be the right thing for us, although some of our brethren might think it a little bit un-craftsmenlike, to call in external aids.

Still, I think you will agree with me that no person can judge of what is an ordinary knowledge, an elementary knowledge, of such a thing as the science of chemistry and the science of botany, as can those who are teaching it day by day, and who know what an elementary knowledge is at the particular time and the particular phase of the science. As we get older and more experienced we—the men engaged in pharmacy—get disposed to examine in the applications of the science rather than in the science itself. It seems to me that teaching should go hand in hand with examining in those two subjects, and I am sure that you cannot feel that our certificates will be any worse if we can induce, as I have reason to believe we shall be able to induce, eminent men engaged in teaching those two subjects here in Scotland, and in England, to undertake the duties of examiners. Nor do I think my colleagues on the Board of Examiners will themselves do otherwise than receive those gentlemen with the consideration they deserve, and with the desire to make the certificate, if anything, more worthy of the men who in future receive it.

It was quite impossible for me to deal with the challenge Mr. Currie throws out without giving you a slight history of pharmacy. You will see from what I have said that I consider that the present pharmacy law is defective in many ways. I have told you perfectly and in a friendly manner, but at the same time most frankly, in what way I think the law should be modified and altered. I have spoken my mind clearly about company trading and the "Widows' Clause," and I leave it to you and such as you throughout the kingdom to tell us at Bloomsbury Square what you would like us to do. I have attended now for nearly thirteen years to your presidential duties; from the age of twenty-two I have been an officer of the Society, working continuously for it. I hope I have done my best to be loyal to every man, whether connected with the Society or not, but I tell you plainly, gentlemen, that I will not, nor will my Council, move in the direction of trade matters in the House of Commons—though we may go in for some matters of internal arrangement—until we are assured of the support of the trade at our back. And we are, I think, entitled to ask for that, and we cannot listen to any criticisms or any grumblings from any of you until you distinctly lay down and agree amongst yourselves what you will go for. And when you have done that I ask you to support us loyally. I cannot ask all of you to join the Pharmaceutical Society—at least, I can, I think it would be a good thing if you would, if there are any here who do not belong to us—if I, however, cannot ask you all to join the Society, I can at least ask a majority of the trade to enrol itself under the banner of the Society. The question of finance is not a very serious matter, even at a guinea a year. The important thing we want is not your guineas, it is your support, it is your power; it is that power which every man who is working in the various branches of labour is using with great force at the present moment in the government of the country; and you chemists and druggists are lying outside and being beaten by them in the race, and beaten because you will not rally round, as I conceive, the only organisation which will do any good for you. You will not, I venture to say, in regard to the "Widows' Clause" be perfectly logical, and as long as you are in that difficulty it is impossible that even the speaker who is now addressing you, and who is a good deal older than he was thirteen years ago, can do anything for you unless you support him. Give him and his Council the support of, say two-thirds of the trade, and I will undertake to say we can do something for you. With these words, I beg to thank you all.

Mr. Robinson said he had been selected as one of the vice-presidents to move that their very hearty thanks be given to Mr. Cartleigh for the address he had given them. He remembered when he went to the trade sixteen years ago, the first document he saw in the pharmacy was one signed by Mr. Cartleigh, and at that time and for many years subsequently it seemed
to him that Mr. Carteigh and the gentlemen whose names followed were something very little lower than the angels. That was the first opportunity he had had of viewing him in terrestrial substance. He had been anxious to hear what this head and frontier of the Pharmaceutical Society really had to say with regard to the many grievances they had had to bring against. He must say he was perfectly convinced there was a spirit of absolute unanimity underlying all external differences which they had with the Pharmaceutical Society and its Council; that their objects were the same all through, and that the opposition which was supposed to exist was entirely imaginary. He fully believed that if the chemists and druggists were polled that day upon the subject of whether they would have bogus pharmacists or widows carrying on business, he thought not two-thirds, but ninety-nine one-hundredths would say "Away with the widows; let us have genuine pharmacists." He thought that pharmacists both in this endless time to make enough to keep their widows in cases of death, or in some way provide for them by insurance, so as not to deteriorate the tone of their profession, and so that those who come after will not have those bogus companies to contend with. He believed the points were not satisfactorily brought out, and Mr. Carteigh had devoted a considerable amount of attention to give satisfactory explanations. He had very great pleasure, therefore, in asking them formally to accord him a very hearty vote of thanks.

Mr. Boyd said he had listened with very great interest to the historical sketch of pharmacy so very ably given by the President, and thought they owed him a great amount of thanks indeed. He had come there that night at the cost of a great deal of inconvenience, on purpose, no doubt, to encourage them in the work of reform. It was earnestly to be hoped his practical remarks would bear fruit, and that in the future they might be more united when they sought further legislation. He thought that when they were going to Parliament again, before the Bill was drafted they should have a grand conference of the trade [Mr. Carteigh: Quite so!] The Pharmaceutical Council was composed of admirable men, but there was a great deal of the metropolitan spirit among them, and the provinces might think they were not in sympathy with them. He was sure that if they were all united and held a grand conference of delegates from all the associations at some central place, there would be more likelihood of a better Bill being produced, and more likelihood of its being passed. He had much pleasure in seconding Mr. Robinson's motion.

The Chairman then said he thought they ought also to accord a hearty vote of thanks to Mrs. Carteigh for the honour she had done them in gracing their meeting that night. They had also another distinguished guest in Mr. Breemridge. They all knew his name well, and he hoped that none there would have any but happy reminiscences of him and that meeting.

The motions were unanimously agreed to, and the votes of thanks accorded with great enthusiasm.

In acknowledging the votes of thanks, Mr. Carteigh said it was very kind of them, and really quite refreshing to meet with so much enthusiasm. He worked and toiled and was continually sorrowed, and it was quite delightful to hear a good cheer of that sort. It augured well for the success of the Association, to which he desired, on the part of his Council as well as himself, to tender their heartiest good wishes. He knew the special difficulties under which they worked in Glasgow, and he thought they might give the Council credit for showing that they had not lost sight of some means of attempting to alleviate the difficulty that had occurred. He thought, perhaps, the difficulties of what were familiarly called "doctors' shops" were not quite so great as they were some time ago. At all events, if they had done nothing else for Glasgow than this, he thought it was something to the credit of the Council that they had shown that a doctor cannot do what a registered chemist and druggist cannot do—that is, he cannot leave his pharmacy to a person unregistered to dispense and sell poisons. He thought that was a point, although it seemed a small one, that would tell in favour of pharmacy in Glasgow. He felt certain that it was by such knowledge on the part of the people of Glasgow that things were as they were, and he felt certain that the intelligent people of Glasgow, if once they understood this question, would support the chemist and druggist right through. They would see it was in the interest of the country. He would point to the prescribing of remedies and visiting the sick.

For himself he might say that, although it was perfectly lawful for a medical man to keep open shop anywhere—for he could not help thinking that a medical man was privileged by law, and did not wish or claim that that right should be taken away from him—he was doing himself much harm and doing the registered chemist probably greater harm, and he believed the practice was one which was of no good to the people. He had been long known that the faculty of the College of Physicians and Surgeons had practically agreed upon, and in somewhat delicate terms pointed out, the importance of their graduates conforming as much as possible, not only to law, but to a certain code of ethics which were more gentle terms, but which he thought showed plainly what they thought of the whole thing.

At the same time it was for the pharmacists in Glasgow to do all they could to show those doctors that they were doing their business well, to do all they could to conform as much as possible to the law themselves in regard to the sale of poisons, never to omit precautions under the law, because it was known that any one of them was in the habit of even accidentally omitting to carry out the very law under which they were registered, they would give a handle to doctors to say they were superior persons, and could carry on their business with more care and safety. They would see what he meant. With regard to his excellent friend, Mr. Breemridge, of course, next to hating the President they probably hated him, most because he was one of those inconvenient people who asked for money periodically, and he did not wonder that they looked upon him as a bit of a persecutor, but he thought that if Mrs. Carteigh was allowed to come in with the Secretary probably they might between them have salvation.

Mr. Breemridge said he was not going to inflict a speech upon them, but after the very kind reception of his name, he should just like to say how much obliged he was for the cordiality of the welcome they had given him, and that it was a very great pleasure to him to have the opportunity of an address of this kind of their Association. He added that they had his best wishes for the continued success of the Association.

The proceedings then terminated.
POISONING CASES AND INQUESTS.

POISONING BY CARBOXYLIC ACID.

Emma Robins, aged 27, died at Southport on Sunday, November 18, from the effects of carbolic acid, self-administered. Verdict, "Suicide while of unsound mind."—Liverpool Post.

CHLOROFORMING CHILDREN.

Margaret White was sentenced to three months' imprisonment at the Sheriff Summary Court, Edinburgh, on November 28, for ill-using her children, aged 6, 8, and 13 years respectively, and drugging them with chloroform.—Glasgow Echo.

DEATH FROM AN OVERDOSE OF BELLADONNA.

G. L. Murgatroyd, of Middlewich, died on Sunday, November 25, from the effects of tincture of belladonna taken medicinally. Verdict, "Death from an overdose of belladonna."—Liverpool Courrier.

POISONING BY LAUDANUM.

George Powers, aged 52, died at Norton Woodseats, near Sheffield, from the effects of laudanum, self-administered. Verdict, "Suicide during temporary insanity."—Sheffield Independent.

Correspondence.

SIMPLE LABEL CASE.

Sir,—Sometimes little hints are useful, and the one I suggest is useful for keeping dispensing labels clean.—Cardboard cases, such as are supplied with addressed labels, are procured the label, one of which can be pasted on the outside of box. An elastic band is passed round the labels, and the bundle slipped inside the box. As each box usually consists of outer and inner cases, it will serve for the lots of labels.

Sheffield.

G. ELLING.

DEATH OF A FOUNDER OF THE SOCIETY.

Sir,—In the person of Mr. Wm. Cooper another link with the past has gone, and as one who owed him much, I think the present a fitting occasion to offer a tribute of respect and affection, in which my present partner, Mr. Rundle, most sincerely joins. Just seventeen years ago to-day, in conjunction with Mr. Rowe, it was my good fortune to succeed him in the business, which, without affectation, I can say he loved, and from that time till now, notwithstanding his great age, his kindly interest in his old pharmacy, and never let us go without enquiries concerning methods of preparation of those articles of the Pharmacopoeia in which he took interest, and concerning which his memory at 90 was greener than that of many a younger candidate. He was devoted to pharmacy and had a passion for the best; nothing short of it was good enough for him. I remember almost a quixotic incident showing this: When a question arose of buying cheaper coals for the laboratory furnace, "Sir," he said, "nothing is too good for my laboratory." I had met many good men in pharmacy before I knew Mr. Cooper, but never one who more commanded respect; he belonged to that age of self-dependence when individual ability, integrity, and strength of character could carve their way to position, and stand out strengthened by the obstacles they had overcome. Always courteous to others in the grand old style, he never failed himself to command respect. For forty years he conducted the business at Russell Street, which under his close personal care grew and prospered, and the respect and trust which those forty years had gained for the name and reputation of his business was a revelation of his integrity. Like most strong men he would affect a certain austerity, yet lived with him worthily but found at Christmas time something more than was in the bond; and I may mention one other fact that showed this quality. We had the good fortune to have Mr. Cooper
for our landlord, and when, some years ago, it came to his knowledge that competition and stores were reducing the profits of trade, he did what many generous country squires have done, but what few urban property owners think to do. He gave us a new lease at a reduced rental, accompanied by kindly wishes, and without any solicitation from us. It is not in my nature, to speak of his early interest in Bloombury Square and of his close relationship with Jacob Bell and the earlier giants of pharmacy. I have only spoken of the narrow, personal knowledge arising out of my own connection with him. But I believe I have said enough to show something of the upright and generous nature of him who, full of years and honour, has gone to his rest.

Wm. Warren. Russell Street, W.C.

MEDICAL MEN AND MANUFACTURERS.

Sir.—Would not the remarks contained in Dr. Notes' excellent letter have been more with better results on ground not quite so barren as pharmacy. It is pleasing to hear what he has to say, the more so, coming as it does from a medical man, but the question has been discussed three decades among chemists, who, at least, by their apathetic and distrust adoption of things as they are, have accepted the inevitable with that kindly and benevolent grace which characterises them, and grows with us as they increase in stature and wisdom. If such sentiments could have found a prominent position in the columns of the medical press, there might be hopes for a brighter future. The medical curriculum is largely influenced by this condition of things. The com-

petatibility of drugs is so lightly touched upon, and the general requirements of pharmacy so slight that it is scarcely to be wondered at if many medical men are only too ready to adopt a system of prescribing that will save both their time and their reasoning powers; and so long as manufacturers can find prescribers who are willing to become neither more or less than advertising mediums, they (the manufacturers) will continue to thrust their specialties upon them. It is a short sighted policy, this prescribing of proprietary articles; the patient is so easily enabled to obtain a repetition of his prescription from the nearest grocer or draper, without reference either to the prescribing power or the dispensing chemist, that the day is rapidly approaching when neither will be required. As a rule, these combinations of drugs are put up in an acceptable and attractive form, the manufacturer putting the physician in competition with an objectionable accompaniment to the doctor's visit—small wonder, then, if the patient swallows the more readily that which is presented in the most convenient and palatable shape. The French Code is ahead of us in this matter, and if a few hints could be authoritatively borrowed from it, with a view to mini-

mising the objection to medicine. The inconvenience to chemists by proprietary prescribing is great—but it is not for the medical man to consider this; he knows the combination that will bring about the required result, but he does not know how to combine it, and until he is taught the manufacturer will continue to reap profit from his ignorance.

A. F. Keal.

CAMBRIDGE.

BOOKS, ETC., RECEIVED.

DIARY OF THE WEEK.

SATURDAY, DECEMBER 8.

Pharmaceutical Football Club v. Bloombury, at Womb-

holt Farm, Shepherd's Bush, at 3 p.m.

MONDAY, DECEMBER 10.

Imperial Institute.

House Dinner, at 6.45 p.m.

"China and the Causes of its Present Disasters," by Professor R. K. Douglas, at 8.30 p.m.

WEDNESDAY, DECEMBER 12.

Pharmaceutical Society of Great Britain.

Library, Museum, School, and House Committees, at 11 a.m.

Evening Meeting at 7.30 p.m.

Imperial Institute.

Concert Dinner, at 8.30 p.m.

Ladies' Concert, at 8.30 p.m.

Society of Arts, at 8 p.m.

Sheffield Pharmaceutical and Chemical Society, at 8.30 p.m.

"Pharmaceutical Politics."

Sunderland Chemists' Association.

Annual Dinner at the Grand Hotel, Sunderland.

Edinburgh Chemists', Assistants', and Apprentices' Association, at 9.15 p.m.

"Notes and Queries" Conducted by William Duncan.

"Notes on Carabolic Acid," by George Croll.

"Novel Impurity in Chloral," by Alex. Gunn.

"Incompatibility of Codine Sulphate and Hydro-

bromic Acid," by William Duncan.

Imperial Institute, at 6.30 p.m.

Manchester Pharmaceutical Association, at 7.30 p.m.

THURSDAY, DECEMBER 13.

School of Pharmacy Students' Association, at 7 p.m.

"A Piece of Granite," by Harold Read.

"Volumetric Analysis," by F. W. Burgess.

Chemists' Assistants' Association, at 8.30 p.m.

Midland Pharmaceutical Association, at 8.30 p.m.

Social Meeting, with a Chat on Travel Topics, at the Midland Hotel.

Litterpool Chemists' Association.

"Distribution of Plant Life" (with Lantern Illustra-
tions), by Professor R. J. Harvey Gibson.

Liverpool Pharmaceutical Students' Society, at 8.30 p.m.

"Queensland and the Bush Pharmacy," by Mr. Bilington.

"Italian Pharmacy," by H. B. Morgan.

SATURDAY, DECEMBER 15.

Sheffield Microscopical Society, at 8.30 p.m.

"The Stereoscopic Structure of Limestones," by Dr. Sorby.

Pharmaceutical Football Club v. Polytechnic, at Waltham-

stow, at 3.15 p.m. Leave Liverpool Street at 2.53 p.m.

COMMUNICATIONS, LETTERS, ETC., RECEIVED FROM:

REMARKS UPON THE NATURAL ORDER
DIPTEROCARPACEAE.*

BY DIETRICH BRANDIS, E.C.I.E., F.R.S.

Dipterocarps, though widely removed from Conifers in regard to their internal structure as well as in regard to their morphological characters, have yet certain important points of resemblance. They are tall trees, rarely shrubs, and numerous species form pure forests, in which one kind predominates, occupying the ground almost to the exclusion of other species. In Europe we are so accustomed to see extensive areas stocked almost exclusively with the Scotch pine (Pinus sylvestris), the spruce, and — of another family — the beech, that it seems to us quite natural that these trees should have the peculiarity of living gregariously, forming pure forests, with only a small and subordinate admixture of other kinds. In many cases, it is true, the forester's hand has been at work, and has gradually produced pure forests of large extent by encouraging the spread of certain species at the expense of other kinds. The spruce forests which cover the Harz Mountains in northern Germany and the Erzgebirge in Saxony, the extensive larch woods around Dunkeld, are, the former to a great extent, the latter entirely, artificial, and remarkable instances of the skill and perseverance of Scotch and German foresters, though in many cases a certain admixture of other species would have been better. There are, however, extensive tracts of pure forest in Europe where the forester has hardly, or not at all, interfered. On the other hand, we have numerous species in Europe which, though producing good seed in abundance, yet have not the habit of remaining in any large extent. One of the two oaks of northern Europe, Quercus sessili flora, never forms pure forests, but only thrives in company with other species, such as the beech, the hornbeam, and the silver fir. The two kinds of maple (Acer pseudo-platanus and platanoide) and the ash (Fraxinus excelsior) occur in small patches, scattered among woods of other kinds.

In tropical countries, where the number of species is many times larger than in Europe, the traveller and voyager feels surprised when coming upon pure forests of wide extent, in which one species has obtained the upper hand, to the exclusion almost of all others. Yet such instances not rarely occur in the tropics, and among Dipterocarps many species are distinguished by this peculiar character. These species are gregarious in their habits, while other species of the same order are only found scattered in forests of other trees.

Another point of similarity between Conifers and Dipterocarps is that they both produce large quantities of resinous substances. These resinous substances we find, in the younger parts of the tree, invariably in special resin ducts, and these resin ducts, in Dipterocarps as well as in Conifers, are always lined by an epithelium of thin-walled secreting cells. This is the peculiar structure of these resin ducts, and the substances which fill them, in Conifers as well as in Dipterocarps, are invariably aromatic oily fluids. In the larch, the spruce, the cluster pine (Pinus pinaster), and in the pines which furnish the resin of the Southern States of North America, these essential oils are commonly designated as turpentine. In the case of Dipterocarps, they are known under the name of wood oil and camphor oil. In physical and chemical characters turpentine and wood oil are very different substances, yet they have certain points in common. Thus, by exposure to the air, both are transformed into a hard, and, when pure, transparent mass, which is commonly designated as resin.

One kind of wood oil is official in the Pharmacopoeia of India, though not contained in the British Pharmacopoeia. This is the produce of Dipterocarpus lanceolatus, Roxb. and of several other species of the same genus. These trees grow on the east side of the Bay of Bengal, in Chittagong, Arakan, Pegu, and Tenasserim, as well as on the Andaman and Nicobar Islands. The name by which they are known in Chittagong is Gurjun, and hence the product is commonly known as Gurjun oil or Gurjun balsam. In Burmah the generic name is Kanyin. They are tall trees, growing scattered, singly or in small groups, in a dense forest of other trees, from which they generally stand out, and are readily recognised by their straight branchless stem, carrying a widely spreading crown, often 120 feet above the ground. From these trees the wood oil is obtained in the following manner:

Deep niches are cut through the bark into the wood near the base of the stem, the first cut is about 4-6 inches deep and 12-18 inches wide at the base, but narrowing upwards. The bottom of the niche is slightly hollowed out to receive the oil. It oozes out and collects at the bottom of the niche a few days after the cut has been made.

As the oil turns into solid resin when exposed to the air for some time, the pores of the wood on the walls of the niche get clogged, and the oil then ceases to flow. The niche is then remade by chipping off the surface of the walls with the resin on it, or by lighting a small fire in the cavity. From the clean cut, or from the charred walls, the oil then oozes out again for some time. In this manner the niche is constantly enlarged upwards, so that it often attains a length of six feet. A number of niches are cut into one stem, and after some time the procoporous cones to an end by the tree being blown over by the wind, or burnt.

In the wood of old trees of Dipterocarpus alatus, the wood oil is not only contained in the resin ducts mentioned above, but also in those cells of the medullary rays which are elongated in the direction of the radius. This wood oil has two properties, by which it can readily be recognised. It is slightly fluorescent, presenting a greenish opalescence on the surface. Heated to 270°, it becomes turbid and gelatinous (Pharm. of India, p. 32). This wood oil is used to paint woodwork and bamboo wicker-work in houses and in river-boats. It is also largely used medicinally, with good effect in gonorrhoea and certain skin diseases. Its use has also been attended with benefit in cases of true leprosy in its early stages, but it is not a specific against that terrible malady of tropical Asia.

A wood oil of much thicker consistency is yielded by another species, Dipterocarpus tuberculatus. This tree grows in Burmah, and is one of the gregarious species alluded to above. It is called "Eng" (In) in Burmese. Large areas in Pegu and other parts of that country, are stocked...
with forest, in which this tree predominates. In this kind also the oil exudes from the outer layers of the wood when niches are cut into the stem, which is done in the same manner as in the case of the Kanyin. As many as six niches are cut into one stem.

The oil, as well as the resin, of both the Eng and Kanyin, is largely used to make torches. It is mixed with rotten wood, or sawdust, and is neatly wrapped up in the leaves of Liochla peckii and other palms, as well as of the grass Utricularia (Pro
dans). The cylinders are about twenty inches long and two inches in diameter, and are used as candles or torches. To light up the house, torch-holders or large candle-sticks are neatly carved out of wood, to hold two or more of these torches.

Dipterocarpus tuberculatus does not generally grow as tall as the different kinds of Kanyin, but it is a fine tree, with a clean stem, often 100 feet high. In the Eng forest, under the old trees, is an abundance of younger trees of the same kind, of all ages down to saplings and seedlings. The young plants of this species have huge leaves, up to two feet in diameter; they stand so close, that they cover the ground completely, and this makes it difficult for other trees to come up among them. Another point which enables the "Eng" tree to maintain the upperhand, and to gain preponderance over other trees, is that it produces an abundance of good seed every year, or nearly every year, which ripens at the right season, at the commencement of the south-west monsoon, when its heavy downpour of rain, near the forest fires of the hot season have passed over the country. Other trees, which ripen their seeds earlier in the year, cannot compete with the "Eng" tree because a large proportion of their seed is destroyed by the annual fires of the hot season.

Another tree of the same family, the "Sāl," Shorea robusta, Gertn., one of the most important timber trees of Hindustan and the Western Peninsula, also grows gorgeously, forming pure, or nearly pure, forests of immense extent at the foot of the Himalayas and in Central India. Like Dipterocarpus tuberculatus, it produces an abundance of good seed annually, the seed ripens at the right time of year, and it germinates immediately, often before it falls from the tree. The leaves of the young plants are large, and the seedlings of the "Sāl" tree have another peculiarity which stands them in good stead, and which those of the "Eng" tree also possess—they stand much shade while young.

The wood oil is obtained from the "Sāl" tree, but it yields larger quantities of resin. Othert species also of the genus Shorea yield resin, which, in the leaves and younger branches, is, like wood oil, found in special resin ducts, but which in old trees forms huge solid lumps in cavities of the stem and between wood and bark.

Besides Dipterocarpus and Shorea most other genera of this order yield resin in large quantities. As the family of Dipterocarps is at present defined (excluding Ancistrocladus and Lopistria) it comprises 320 well-established species, which may most conveniently be arranged under sixteen genera. Wherever Dipterocarps grow, that is nearly over the whole of tropical Asia, resin is yielded by them. On the Seychelles it is Vateria seychellariun, Dyer, in the Western Peninsula, Vateria indica, L., and species of Shorea and Hopea, in Ceylon, Vateria acuminate, Hayne, species of Doona and Sme
toporus, in the Eastern Peninsula chiefly species of Dipterocarpus, Shorea and Hopea. Trees of the order produce resin in Borneo and the other islands of the Indian Archipelago, as well as in the Philippines and in New Guinea. This resin is not only obtained from the stem. Like the African copal, great masses are found in the ground near the roots of the tree.

The species of one genus, Dryobalanops, do not yield resin, but they furnish a product of far greater value, the well-known Borneo camphor, which is found deposited as beautiful colourless or light yellow crystals in fissures and between the fibres of the wood. This genus comprises a few species only, which grow in Borneo and Sumatra, the camphor produced in Sumatra being commonly known as Baros camphor. The trees are very large, similar in appearance to the wood oil trees. The process is most wasteful, the trees being cut in two ommes being about the largest quantity obtained from one stem. The price is high, 50a. to 95s. a pound. It is exported to China, where it is highly prized as a tonic and aphrodisiac. In Sumatra it is used for the purpose of embalming the bodies of chiefs and other great people. It need hardly be mentioned that the Borneo or Baros camphor is distinct from the camphor of Japan and Formosa, the product of Cinna
umomum camphora and from the Ngai camphor, the produce of a large herb of the Composite, Blumea balsamifera, D.C., which grows up in abundance on deserted "Tonugyas" (hill clearings, where one crop of rice is raised after cutting and burning the forest) in Burma, Siam, and Southern China.

As in the case of the species of Dipterocarps previously described, the resin ducts in the leaves and young branches of Dryobalanops contain an essential oil known under the name of camphor oil, and this is obtained from incisions in the trunk.

The seeds of Dipterocarps as a rule contain no aril, but are filled up entirely by the embryo with two cotyledons, which in most cases are biform to the base. Generally they are thick and fleshy, or, if flat, much twisted and corrugated. In most species the cells of these cotyledons, as well as those of the radicle, are filled with starch, which, when the seed germinates, is expended to feed the seedling until the first green leaves have been formed, and the root has commenced to act. In some species, however, belonging to the genera Shorea, Isoperla and Vateria, the embryo grows up without any starch in the seed consist not of starch, but of a fat oil. This Fat, when pressed out from the seed, is not fluid like the oils of rape or linseed, but has the consistency of tallow. On the west coast of India the seed of Vateria indica, L., yields large quantities of a beautiful white tallow, known as pinny tallow or vegetable butter, which is made into candles and sold in the bazaars of Kanara. The Journal of this Society for 1884 (page 407 and 428) and for 1887 (page 501) contains valuable articles, translated from the Dutch on the subject of the "Tang Kawang" Fat or vegetable tallow, the produce of Isoperla bornensis, and of several species of Shorea, which grow on the island of Borneo. And the Museum of this
Society contains a most valuable collection of specimens of these trees, as well as of the "Tang Kauwang" fat, preserved in the original hollow bamboo in which it is collected by the natives of Borneo.

THE SPAGIRISTS.

BY JOSEPH INCE.
Lecturer in Pharmacy to the Pharmaceutical Society of Great Britain.

The 'Art of Distillation,' by John French, Doctor of Physick, has for a sub-title, 'A Treatise of the Choicest Spagirical Preparations Performed by way of Distillation.' The book also contains a discourse on divers spagirical experiments. In both instances the medieval adjective is used as synonymous with chemical, which is not the exact historical meaning of the word, but a later application.

It might, perhaps, be interesting to know what the sect of the Spagirists was, and what was intended by the arts spagirios, or spagiria; the subject may claim some pharmaceutical importance, and yet be of a truth untimely. Much fanciful farrago has directly influenced the science of to-day, and has received in the nineteenth century its fullest interpretation.

Many dictionaries adopt a popular definition of spagiria, and explain it as either alchemy or chemistry; other authorities say that Poraeceaus coined the word "spaher," the searcher; but standard works of reference, with great unanimity, derive the term from σφαῖρα, to separate, and σφαίρεω, to unite. This is further stated by some to point to the two chemical processes of analysis and synthesis, but considering the date of the text, which flourished during the sixteenth century, when exact experiment was rare and science was in a nebulous condition, this is giving more credit than is due. I would rather adopt the words, "to bind and to loose," which about expresses the truth.

Spagiria and alchemy cannot be considered as synonyms if history is to be taken into account; the Spagirist was the successor, and infinitely superior to the alchemist, and Vossius may be quoted as an authority:

"Poraeceaus dici a duobus artes officia qua sunt resolvendae composita et resoluta componere. Nam, σφαῖρα tradit, extrahere: σφαίρεω, congregare."

I think, however, that arts are said to be spagiritic from two functions, which are: to separate things combined, and to combine separate things. For σφαῖρα means to draw; to draw out: σφαίρεω, to comb ne3.

Coming to closer definition, we find that Paracelsus was the first who applied the term to chemical medicine. Spagiria was the revolt, or rather the emancipation from, the restricted medicine of the age which sought for remedies only in the vegetable kingdom; the Spagirists enlarged the boundaries of therapeutics by the introduction of remedies drawn from inorganic sources; the first outcome of the new departure was the exhibition of antimony as an emetic. The chemist studied the nature and reactions of chemical substances; the Spagirist devoted himself to their use in the healing art; the alchemist dreamed dreams and saw visions of the elixir of life and the philosopher's stone.

The sect of the Spagirists is accurately described in the 'Dictionary of Medical Science' by Robley Dunglison (1839): "A sect of physicians pretending to account for the changes in the human body in health and disease in the same way as the chemists formerly explained those of the organic kingdom." 'Le Dictionnaire Encyclopédique des Sciences Médicales' (1881), edited by A. Dechambre, other French writers, various English medical dictionaries, and, lastly, Dr. Paris in his 'Historical Introduction,' give particulars relating to the professors of the art spagirici. Basili Valentine led the way by experimenting on the nature and internal administration of antimony; up to this date metallic remedies (iron excepted) had been confined to external application.

In the 'Triumphant Chariot of Antimony,' Brother Basil (b. 1394) writes: "The shortness of life makes it impossible for one man thoroughly to learn antimony, in which every day something of new is discovered."

Paracelsus (1490), charlatan and chemist, afterwards became the champion of antimony, and was the first to introduce the internal use of mercury. Van Helmont recommended alum in uterine hemorrhage; while numbers whose names need not be chronicled followed in the same path.

Joseph Du Chesne (Quebecanus), physician to Henry IV. of France (1553), Israel Harvet, and Guillaume Baucinet (both from Orleans), Andre Libavius, and their immediate followers, raised the study and practice of chemico-medical therapeutics in a remarkable manner, and obtained results as important as unexpected.

The system was officially recognised in the reign of Henry IV. (mentioned already) when the title of Physician-Spagirist to the King (medecin-spagiriste du Roy) was conferred on Mathurin Morin, a post which was continued during subsequent reigns.

A celebrated Spagirist under Louis XIII. was Guillaume Yvalin (1611-1613), four official Spagirists flourished under Louis XIV., and one, Eloy Picot, retained a court position so late as Louis XVI.

Great excess characterised the early stage of this movement, in itself excellent and exoelior, but that was the tone and temper of the age. The chemists, as a sect, traced every obscure disease to the presence of some hostile acid or alkali; the Spagirists, as a sect, maintained that chemical bodies were a panacea for all the ills to which flesh is heir; the orthodox physician despised them both. The Galenists began to tremble for their reputation, and war, which waged for two centuries, was openly declared. In France, the Paris Faculty of Medicine rose up and denounced the system. Guy Patin was a special opponent, virulent and sarcastic. Spagiria was called the true doctrine of the pest (la pure et vraie doctrine de la peste); amongst innumerable diseases was one on 'Spagirico Impostors: A Treatise against the rash presumption and intolerable imposture of the Spagirists,' with kindred specimens of gall and bitterness.

The Supreme Council of Paris (1566) was appealed to, for a time successfully, to put down the insurrection against the hitherto received canons of medical practice. The progress of discovery could not, however, be arrested, and in 1668 calomel, the very type of the spagiric art, was made known. In the midst of these disputes the
term "medical orthodoxy," or "orthodox medicine," originated. The Hon. Robert Boyle [Works, vol. 1, fol. 463] regretted the extremities to which both parties were committed. The chemists, he said, looked upon the Spagirists as a company of mere irrational impostors, whose services might be serviceable to apothecaries, and perhaps to physicians, but were useless to a philosopher who aims at curing no diseases but that of ignorance. The Spagirists looked upon the corpuscularians (chemists) as a sort of empty and extravagant speculators who pretended to explain the great book of nature without reference to the phenomena which the spagiric art had revealed.

Towards the middle of the 17th century, the word spagiric ceased to be used in a restricted sense, and received the wider acceptance of "chemical," which accounts for some apparent contradictions in works of reference.

It may be repeated, that the term "spagiria" indicated the medical application of substances taken from the inorganic world; the Spagirists were the sect who introduced and practised that system—it is what is called, in French, "La Chimie Médicale." The moment it was set free from irrational dogmatism, and was recognised as an integral part, but not as the whole, of medical treatment, its influence was immense and permanent. It wonderfully strengthened the physician's hands, and gave him a new power. Pharmacopoeias of all nations (after a certain date) exhibit a long array of spagiric remedies. Pharmaceutical research laboratories are one of the latest developments of spagiria.

The difference between the old system and its modern application is, that those concerned with medicines have discarded the vain imaginations and fancied claims of imperfect knowledge in favour of the accurate methods of investigation of the present day; but should they, despising the florid verbiage of their ancestors, fail to recognise the teaching of the pioneers of the spagiric art, they must cancel many pharmacopoeias and close all research laboratories in connection with, and devoted to, the chemistry of medicine.

**NOTES ON OPOPANAX**

BY E. M. HOLMES, F.L.S.

Curator of the Museums of the Pharmaceutical Society of Great Britain.

The name "opopanax" (i.e., the juice of Panax) is better known at the present day in connection with a perfume so called, than with the gum-resin which under that name was at one time extensively used in medicine. With the exception of sagapenum, hardly any other gum resin is now so little known. Even its botanical origin has been, up to the present time, involved in obscurity, and with the exception of Merat and De Lens, most writers on materia medica assumed that it was obtained from a plant indigenous to Greece and Eastern Europe, viz., Opopanax chironium, Koch. This error probably arose from the fact that these panaxes, or Panax plants, are described by Dioscorides.

The authors of 'Pharmacographia' remark concerning this error:—"We have never seen a specimen obtained from this plant, but can say that the gum-resin of the nearly allied Opopanax pericicum, Boiss, as collected by Loftus at Kirrind, in W. Persia, in 1851, has neither the appearance nor the characteristic odour of official opopanax. Powell, who endeavoured to trace the origin of the drug, regards it as a product of Persia ("Economic Products of the Punjab, 1868," p. 403). Opopanax was very common in old pharmacy, but has fallen out of use, and is now both rare and expensive."

The above is the most trustworthy account of the drug that I have seen. I have tasted the leaves of Opopanax chironium as cultivated in the Apothecary's Garden at the Sibthorpe Botanic Gardens, and find that the plant has not the least resemblance to opopanax in flavour. I can also confirm Powell's suggestion as to its geographical source. I have learned through Messrs. G. N. Souratty and Co. that it is imported from Persia. Acting on this information I endeavoured some years since to obtain the plant, but, owing to various causes—amongst others the prevalence of cholera in the district where it grows—I was unable to get specimens. About two years ago Mr. W. Martindale kindly informed me that Dr. E. Treacher Collins was going to Persia to attend the son of the Sultan, and would be very pleased to make enquiries about any Persian drugs. The results of his enquiries (which I suggested should include the botanical sources of opopanax, sagapenum, and galbanum) were received about two months ago, and the opopanax brought by Dr. Ollis proved useful in tracing the source of the drug. Judging from the specimens received, the gum resins, when carefully collected from the stems and flowering tops, has a most powerful odour and an equally strong taste of celery. It is then in small grains and has a pale brownish-yellow colour. In the specimens that have been gathered from the root the gum resin is more disagreeable, and possesses the characteristic odour of bruised ivy leaves which old or inferior specimens of the drug invariably give off, but even these possess the celery taste. In Persia the name of the plant is "Kalasos," or wild celery. This flavour in opopanax was quite new to me, but it throws some light upon the drug. Under Levisticum, which has also a celery flavour, Dioscorides remarks that it is called by other writers Panakes or Panaee, indicating that the drug Panakes, or opopanax, had a flavour like that of Lovage (Levisticum officinale, Koch), and the genuine opopanax, attributed to a species of Heracleum, apparently possesses the same flavour. The use of the drug in Persia as a condiment and stomachic suggests the possibility that this might have been the Asa dulcis of the Romans, since such a flavouring agent would have been much more acceptable than saffedita, and a small quantity of opopanax would be much more powerful, and therefore more economical, than Lovage.

It is remarkable that, although the same odour is found in a number of plants and in different natural orders, its chemical nature has never been determined. The following plants, Trigonella foenum-graecum, and Melilotus carulea in Leguminosae; Levisticum and Osmorhiza in Umbelliferae; and Umbra fulva in Urticaceae, etc., possess it in a remarkable degree. Concerning the botanical source of the opopanax, I can only state that the drug is collected from plants growing on the mountains to the south-east of Isfahan.

A specimen of opopanax recently presented to the Museum by Messrs. T. Christy and Co. exactly
corresponds with Dr. Collins' specimens. I understand that this gum-resin has recently been exported to Germany in considerable quantity for so rare and expensive a drug.

With regard to the perfume called oppopanax, I find that the oil of oppopanax of perfumery is obtained from a gum-resin which has a totally different origin, being derived from *Commiphora kotsch* Eng. Borrerraeae. It is the "Bisabol" of Pharmacopoeia (2nd Ed., p. 145), and the perfumed bdellium of Dymock, Mat. Med. India, p. 158-9. In appearance it resembles oppopanax and myrrh also, but it has a lightly pleasant and quite distinctive odour.

**EUCALYPTUS OIL.**

*BY E. M. HOLMES, F.L.S.,
Curator of the Museums of the Pharmaceutical Society of Great Britain.*

Oil of eucalyptus holds a somewhat anomalous position in perfumery. It is official in the Pharmacopoeias of Great Britain, the United States, France, Japan, and Belgium, but is not so in those of Germany, Holland, or Switzerland. Indeed, it is stated by one of the largest manufacturers of essential oils in Germany that there is comparatively little public demand for the oil in Germany, and that the same is the case in France.

Yet it has been stated in some of the leading medical periodicals in this country and on the Continent to be three times as strong as carbolic acid in preventing the development of bacteria. In this country it was so largely used as a prophylactic during the epidemic of influenza that at one time it was scarcely procurable in commerce. But the quality and character of the oil have always been uncertain. This inequality has arisen from the fact that different species have been used for the distillation of the oil. At first *Eucalyptus amygdalina* was used, then *E. oleosa*, *E. dumosa*, *E. globulus*, *E. cneorifolia*, *E. odorata*, and probably other species were used. These oils differ greatly in composition.

In some phellandrene has been found, and in others eucalyptol as a principal ingredient.

The reputation of the oil rests upon a very unsatisfactory basis. On the one hand, eucalyptol is claimed to be the active ingredient, whilst on the other, phellandrene is the constituent in the oil on which partly its reputation is based. We do not know at the present moment how far the antiseptic action is due to ozone, to eucalyptol, to phellandrene, or to some of the aldehydes which are known to be present in the oil. It may even be to one of the latter class of bodies, and it is likely that some aldehydes—formaldehyde, for instance—are powerful antiseptics. The chemistry is, in fact, far in advance of the therapeutic and physiological knowledge of the oil. The principal object I have at present in view is to direct attention to the statement that eucalyptol can now, by virtue of Faulding's new patent process, be prepared in a perfectly pure state by the decomposition of its phosphoric compound and that it is therefore quite possible for pharmacologists to determine its real value or otherwise by actual experiment. If it be proved to be the most important ingredient in the oil, its adoption in the Pharmacopoeia, instead of an oil which may be uncertain in its percentage of eucalyptol, and certainly is often variable in its odour according to its botanical source, would be much more satisfactory; in all probability not only to the prescriber and the dispenser, but to the patient.

Should, eucalyptol however, not prove to be the most valuable constituent of the oil, it may be useful to direct attention to the other known constituents of the oils of eucalyptus that have been offered in commerce, and to give a brief description of one of the most recent processes adopted for their distillation, inasmuch as the methods of distillation probably exert some influence on the character of the products.

The chemical examination of some of the eucalyptus oils has shown that nearly 25 per cent. of the bulk of the oil usually consists of some terpene, apparently limonene in most cases, but in others pinene, the remainder being composed in large proportion of eucalyptol, or in a few cases of ketones.

There have also been found in the eucalyptus oils of commerce, phellandrene, and a heavy saponifiable oil, each in the proportion of about 10 per cent., and, in smaller quantities, various bodies, some of which belong to the class of aldehydes. The latter possess the property of irritating the air passages when the oil is inhaled. Whether any of these bodies are actually present in the leaves of the plant, or are formed under the influence of heat, by the aid of the natural acids present in the leaf, has not yet been determined. In any case they differ in different species, some coming over in the first part of the distilled oil, and others in the last part. Thus cuminie aldehyde has been detected in the oils of *E. cneorifolia* and *E. hemiphloia*, valeric aldehyde in *E. rostrata*, and butyric, caproic, and valeric aldehydes in *E. globulus*, as well as ethyl and amyl alcohols. Some doubt has been expressed as to the occurrence of phellandrene in the oils as distilled from the plant, although it has certainly been found in several of the oils of commerce.

For the following account of the method of distilling the oil in Australia I am indebted to Mr. E. E. M. Payne, who has seen the process conducted in that country.

"The process commonly adopted for the distillation of the oil is as follows:—The fresh leaves are packed in the still without water and steam is passed through them. The steam on condensation leaves in the receiver an oil which in the case of *E. cneorifolia*, *E. goniocalyxe*, and *E. incisa* is of a dark colour; in the oil of *E. odorata* the colour is of a faint green."

"The crude oil thus obtained is mixed with a solution of caustic soda and re-distilled in order to remove the irritating bodies and saponifiable oils of high specific gravity, 950—970; the aldehydes do not appear, however, to be entirely removed by this process. The distilled oil thus obtained forms the ordinary eucalyptus oil of commerce."

"About 10 per cent. of the original oil is left in the still, partly in combination with the sodium hydrate, forming an acid soap insoluble in water. This impure liquid soap is of a dark colour and syrupy consistence. It is commonly known amongst distillers as 'eucalyptus tar' or 'resin oil,' although it does not contain any true resin."

*Paper submitted at an Evening Meeting of the Pharmaceutical Society, on December 12.*
Australia it is sometimes employed as an ingredient in cheap disinfectants and for adding to perfumes for soaps, but it is often thrown away. By acting upon this eucalyptus tar with a strong non-corrosive acid a heavy oil can be separated (of specific gravity 0.970) in the case of K. oil, which differs in odour and character according to the variety of Eucalyptus from which it is made. In no case, however, is its composition accurately known."

It may here be remarked that the removal of 10 per cent. of a heavy oil, by reducing the volume of the original product, naturally increases the apparent percentage of eucalyptol. The amount found in commercial specimens of the oil has been estimated at 60-70 per cent. According to Mr. Payne's experience, however, this is decidedly above the average amount contained in the crude or natural oil. In some careful experiments conducted by him with the view of determining the average amount of eucalyptol present in the leaves of E. odorata during the season from October to May, the whole of the produce (1500 tons of leaves) collected during that time was examined, and the average was found to amount to exactly 50 per cent. of eucalyptol. The percentage varied a little according to the weather, a rise of temperature increasing the amount of eucalyptol, and a fall decreasing it.

In none of the oils examined, viz., E. odorata, E. mcerifolia, E. incrassata, E. goniocalyx, and Melaleuca uncinata, did he find the percentage to exceed 55 per cent., nor did it fall below 45 per cent.

The specific gravity of the oil cannot always be taken as an indication of its richness in eucalyptol, for in a sample of the oil distilled from the young leaves of E. odorata of less than one year's growth, the specific gravity was lower than usual, owing to the absence of the heavy oil, and to the larger proportion of limonene, although it contained the average amount of eucalyptol.

Eucalyptol is now separated by adding syrupy phosphoric acid to eucalyptus oil, when a crystallised compound separates out. The "phosphate of eucalyptol," so formed is decomposed in contact with water, and the eucalyptol can then be obtained in what is affirmed to be a perfectly pure state, inasmuch as it possesses no odour of the aldehydes, but does possess the melting point, specific gravity, boiling point, and activity as regards polarisation, that characterise the pure article. This method, which has been patented for manufacturing purposes as "Faulding's process," can therefore be utilised as a test of the presence of eucalyptol in any given oil, or of the purity of eucalyptol itself. It is employed for the determination of eucalyptol in eucalyptus and other volatile oils, and its extraction from the same oils.

Seeing that the properties of the other ingredients of eucalyptus oil are unknown, and may yet be of value an oil has been placed in commerce, derived from E. odorata, and standardised to contain 50 per cent. of eucalyptol. This is intended to serve as a perfectly pure oil, containing all the normal constituents in the average proportion, for use in cases in which such an oil may seem preferable to eucalyptol.

THE NEW EDITION OF THE PHARMACOPEIA.

REPORT OF THE PHARMACOPEIA COMMITTEE.

The following is the text of the report of the Pharmacopoeia Committee, as received and entered on the minutes by the General Medical Council on December 5, and published in last week's Lancet:

"The Registrar reported that, since the last meeting of the Council in November, 718 copies of the British Pharmacopoeia, 1885, have been sold; that the total number of copies sold up to the present date have been 41,718; and that 1090 remain in stock; further, that 579 copies of the Additions of 1890 have since been sold, that the total number sold to the present date have been 13,304, and that 193 copies of the Additions remain in stock.

"The Committee has to report, in connection with the proposed extension of the operation of the Pharmacopoeia to India and the colonies, that a large number of very satisfactory official communications have been already received by the President, through the Privy Council, from those distant dependencies of the Crown, and recommends that the thanks of the Council be returned for the same, with a request that the several Indian and colonial medical and pharmaceutical authorities be well enough to continue to aid in the production of this edition.

"The Committee recommends that, in accordance with the instructions of the Council, and as in the production of the British Pharmacopoeia of 1885, and its Addendum of 1890, the President of the Council apply to the respective medical authorities of Great Britain and Ireland, asking their co-operation and assistance in the compilation of the proposed new editions of the Pharmacopoeia, more especially as regards omission alterations, and additions, the authorities being requested to reply before March next.

"The Committee, remembering the valuable assistance given to the Medical Council by the Pharmaceutical Society of Great Britain in the production of the Pharmacopoeia Addendum of 1890, recommends that the invitation to that Society to assist in the compilation of a new Pharmacopoeia be forwarded at once, as regards the obtaining of trustworthy statistics respecting well-recognised non-official remedies which are largely in demand, and respecting those official remedies which appear to have become superseded, the Society to reply before March next. Further, the Committee recommends that the Council of the Society be invited, as heretofore, to give to the Medical Council, before May next, the names of pharmacists who would be willing to serve on a Pharmaceutical Pharmacopoeia Committee, under the guidance of the Society's Council such Committee finally reporting, with the concurrence of the Society's Council, to the Medical Council, through the Pharmacopoeia Committee of the latter Council.

"The Committee has taken note of the opinions expressed in the Council on the question of associating with Professor Attfield one or more persons conversant with other than the pharmaceutical aspects of the work of the editorship. The question whether
this is necessary and practicable will be carefully con-
sidered by the Committee and will be reported upon
to the Council at its next session. The Committee
thinks it most important that the Council should be
fully informed as to the method adopted in preparing
previous editions of the Pharmacopoeia, and more par-
cularly the last edition. It first appointed an editor
or editors in pursuance of the terms of section 54 of
the Medical Act, 1858. The Committee then adopted
the following memorandum:—

"The Committee is desirous of enlisting the
co-operation of the several medical and pharmaceutical
authorities, and of such persons as may be able to
furnish useful information, with the view of rendering
the work as complete and accurate as possible. In
furtherance of this object the Committee invites, and
will be happy to receive, such suggestions as may be
made to it by the above-mentioned authorities, and
to give these suggestions most attentive con-
sideration."

"This memorandum was sent to nineteen medical
authorities, thirty-two pharmaceutical authorities, and
forty-one persons known to be competent to advise
and assist the Council. In response about 350 replies
were received. These were arranged, printed, and
submitted to each member of the Pharmacopoeia Com-
mittee. The replies had reference, not only to the in-
sertion of new medicines and the omission of obsolete
ones, but to many alterations and changes in the
composition of medicines, to doses, and the like
Especially valuable were the replies upon these points
from the Royal College of Physicians of London. The
Committee proposes to address a like communication
to the several authorities as on previous occasions
and to invite them to send to the President such sugges-
tions as they may be pleased to offer before the end of March next. All such suggestions will then be
arranged in a convenient form, printed, and sent to
each member of the Pharmacopoeia Committee prior
to the next session of the Council. The Committee
will then consider whether its members feel capable
of themselves deciding upon the medical questions
raised by the various suggestions, as they have hitherto done, or whether they feel it necessary to
seek assistance of this nature outside the Committee.
This point will be best determined when the whole of
the suggestions are before the members. The Com-
mittee further recommend that at the Council's meet-
ing in May next, the constitution of the Pharmacopoeia Committee be considered."

 pound or preparation.

The Pharmaceutical Journal

FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, DECEMBER 15, 1894.

Editorial Department.

Communications for the Editorial department of the
Journal, books for review, &c., must be addressed to the
"Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to
"Street Brothers," 6, Serle Street, Lincoln's Inn
London, W.C. where copies of the Journal may be
purchased. Cheques and money orders must be made
payable to "Street Brothers."

Instructions from Members, Associates, and Students
respecting the transmission of the Journal must be
sent to the Secretary—Mr. Richard Bramridge,—
17, Bloomsbury Square, London, W.C.

THE REVISION OF THE PHARMACOPEIA.

At the meeting of the General Medical Council, on
Tuesday, December 4, the report of the Phar-
macopoeia Committee was discussed, but the motion of
Sir Dyce Duckworth, that it be received and
entered on the minutes, was defeated, and an amend-
ment carried that it be re-committed. Dr.
Tuke, in moving the amendment, objected that the
Committee had had no adequate opportunity of
studying and considering the report, the draft of
which was presented at the hour of meeting only,
and he urged that, under the proposed arrange-
ments, the new work would be purely a pharmacists'
pharmacopoeia. In his opinion, also, one expert
physician from each part of the kingdom should be
associated with the editor in the work, whilst the
sum proposed for the remuneration of the editor
was excessive, being out of proportion to his view
of the work to be done.

The President, Sir Richard Quain, Bart., said
that Dr. Tuke had formed misconceptions on the
subject owing to his ignorance of the facts of the case,
and he believed the main ground of offence was the
proposed consultative committee, consisting of four
English members—the President, Sir Dyce Duck-
worth, Dr. Leech, and Mr. Carter. That com-
mittee, however, would have no authority what-
ever, the object being simply to have some one on
the spot in cases of doubt, to whom the editor
might refer. There had been a suggestion for
the introduction of pharmacology into the Phar-
macopoeia, but the Medical Council had no power
and no funds for that purpose. Drs. Leech, Mac-
Allister, and McVay also supported the amend-
ment, whilst Dr. Bruce said they seemed to be
drifting into a pharmacists' pharmacopoeia, instead
of a medical one. On a vote being taken, the
amendment was carried by 12 to 9.
The subject, having been re-considered in the interval by the committee, was again brought up on Wednesday, December 5, when Dr. MACALISTER stated that the first and second paragraphs, of the report presented on the previous day by Sir DYCE DUCKWORTH stood as originally drafted, but certain alterations had been made in subsequent paragraphs and others were deleted in their entirety. Finally, the report, as amended, was adopted. The full text of the report will be found at page 502), of the Journal.

THE TREATMENT OF Diphtheria.

Dr. SIMS WOODHEAD, the director of the research laboratories of the Royal College of Physicians and Surgeons, read a paper at the Examination Hall, on December 7, on the antitoxin treatment of diphtheria, under the auspices of the British Institute of Public Health.

The lecturer first dealt with statistics of the incidence of diphtheria in England during the last five years, and pointed out that the mortality had diminished during that period in this country, so that at the present time it was only about 23 per cent., against an average of about 50 per cent. in France. Not only had that fact to be kept in mind when dealing with the statistics of the antitoxin treatment, but also the ages of the patients: the disease has been found to be much more fatal in children under three years of age than in older subjects.

The history of the antitoxin treatment was traced much as it has already been given in our columns, and the morphology of the bacillus and the methods of cultivation were beautifully illustrated by line-light projections. The colonies grow quickly—more quickly than those of any other bacillus usually met with in the human mouth—and form rounded white colonies with crenated margins. The method adopted by the State authorities in America for the bacteriological certification of diphtheria consists in supplying the practitioner with a small cardboard box enclosing two test-tubes, of which one contains solidified nutrient serum, and the other a steel probe with a pad of sterilised cotton wool at its lower end. Both tubes are plugged with sterilised cotton wool. The practitioner removes the plug from the tube containing the probe, presses the padded end of the latter, first on the surface of the suspected membrane in his patient’s throat, and secondly on the slanting surface of the serum. This done, the culture tube is re-plugged, the probe and the plug are replaced in the other tube, and the whole apparatus despatched to the bacteriologist, who is able to make a diagnosis within twenty hours. Clinical diagnosis will not, however, be entirely relinquished, even by the most advanced phystologists, for Dr. WOODHEAD informed his hearers that sometimes the bacilli disappeared from their habitat—the surface of the diphtheritic membrane—long before the case was over, and, on the other hand, they had been found in the mouth some weeks after the membrane had disappeared and convalescence had set in. The latter fact is of great importance for the investigation of epidemics in schools.

The lecturer showed in full detail, by photographs, the method of preparing the supply of toxin for use in immunising animals. A shallow layer of nutrient broth is placed in a covered glass dish, furnished with two openings. After inoculation, one of the openings is fitted with a tube, which brings a current of air filtered through cotton wool and saturated with water by being passed through a wash-bottle. The stream of air is kept up by the ordinary method of aspiration, that is by passing a continuous jet of water over the extremity of a glass tube fitted to the second opening in the culture-dish, and the whole apparatus is so arranged that it can be kept in an incubator at a temperature of 37° C. In this way large quantities of the toxin can be prepared in a few weeks. The manner in which the strength of the antitoxin is gauged was also explained. Equal quantities of toxin of known potency are placed in a series of test-tubes, and then antitoxin is added to the tubes in amounts which decrease from (say) one-fifth of the amount of the toxin in the first tube, to one-fiftieth in the tenth. It is then found by experiment what is the lowest proportion of antitoxin which completely neutralises the poison. After reviewing the whole of the evidence, the lecturer most earnestly advocated a full trial of the antitoxin in this country, and at the same time urged his hearers not to regard the success of the treatment as already proved.

Lord PLAYFAIR, in proposing a vote of thanks to Dr. WOODHEAD, said that he hoped the mistaken action of a certain body of persons, whose motives he approved, would not prevent this country from doing its plain duty, and vindicating its claim to common sense in having the new method of treatment fairly tested.

PROCEEDINGS UNDER THE PHARMACY ACT.

We have from time to time commented upon the difficulties that interfere with the proper administration of the Pharmacy Act of 1868, and the case at Mansfield, of which we publish a report on page 519, exemplifies a difficulty which most decidedly ought not to exist. In this case the defendant appears to have had some pharmaceutical experience in his early days, but he had not seen fit to become registered under the Act before commencing business on his own account, and the manner in which he supplied poisons to his
customers was such as to render the proof of sale extremely difficult. The County Court judge was not satisfied that the case was thoroughly made out, and, accordingly, gave the defendant the benefit of the doubt, but he thought the Society was quite justified in bringing the case forward, and disallowed defendant’s costs.

The main interest in the case, however, centres in the fact that the defendant was apparently aided in the unlawful supply of poisons by a registered pharmaceutical chemist, who himself gave evidence for the defence. This indicates a state of affairs which cannot be too strongly deprecated. If the Society, in its efforts to protect the interests both of the public and of pharmacists, is to be not merely unsupported by at least the sympathy of the trade but thwarted in its endeavours, it is a little difficult to see upon what ground those who help themselves so little can expect to be protected from the evil effects of their own misdeeds.

If any registered man objects to the policy pursued by the Pharmaceutical Society and abstains from connection with it, he is in no degree absolved from the unwritten yet general rule that the members of a given craft should be prepared to sink all differences when the Act under which he is registered is being infringed. The least that is expected from him is to behave honourably to his fellow-pharmacists, and this he certainly does not do when he assists unregistered individuals, directly or indirectly, in their attempts to infringe the provisions of the Pharmacy Act with impunity.

On the same day a very similar case was heard at Aberavenny, where a grocer named Pegler had sent out for a bottle of Fellows’ syrup and supplied it to the purchaser. Here, however, the proof of sale was less difficult, a receipted bill having been given, and judgment was given for the Pharmaceutical Society. A report of the case will appear in next week’s Journal, as will also that of a case at Oldham, on Thursday, when judgment was given for two penalties and costs against W. Schofield, medical botanist.

**NAVAL DISPENSERS.**

It appears, according to a communication received by the Council of the Pharmaceutical Society of Ireland from the Director-General of the Naval Medical Department, that persons registered under the Irish Pharmacy Act are regarded as ineligible for the post of dispenser in the Royal Navy. Considering the high standard of education maintained by the Irish Society, this exclusion of its graduates from the public service is both impolitic and unjust, and it is to be hoped that the present inequality under which they suffer in this respect may soon be removed.

**MISCELLANEOUS NOTES.**

At the moment of going to press we learn from Mr. Thomas Hanbury that he has received a telegram stating that Professor Flügge is dead.

At a meeting of the Privy Council on the 11th inst., the recent appointment of examiners by the Pharmaceutical Council was confirmed.

The chemists’ twenty-ninth annual ball will be held at the Portman Rooms, Baker Street, W., on Wednesday, January 16, 1895. Mr. Dan Godfrey’s quadrille band will be in attendance, conducted by Mr. Dan Godfrey. Applications for tickets (ladies’, 12s. 6d.; gentlemen’s, 17s. 6d.), which must be accompanied by a remittance, should be made to the Honorary Secretary, Mr. A. J. Phillips, 156, Cromwell Road, South Kensington.

At a recent meeting of the members of the Blackpool Scientific Society, Mr. C. H. Turver, chemist and druggist, read a paper on “Money, its uses and origin,” in the course of which he pleaded for the adoption of the decimal system, and moved the following resolution:—“That it is the strong opinion of this meeting that the system of weights, measures, and coinage at present in use in this country is inconvenient, anomalous, expensive, and detrimental to trade and commerce, as well as to the interests of society; and it is strongly urged that steps be immediately taken to introduce the metric system.”

Illustrations of the soldering of aluminium by the process of M. Ludwig Oliven were given at the offices of the Planet Electrical Engineering Company on Thursday, November 29. The details of the process were not made public, but it is stated that several articles were soldered so effectually that when sufficient force was applied to tear the metal, the joints remained perfectly firm.

At the examination for open science scholarships held last week at St. John’s College, Cambridge, Mr. G. S. Warry, son of Mr. Wm. Warry, chemist, Bradford, headed the list of successful candidates, and was awarded a foundation scholarship of eighty pounds per annum.

The chemists of Dumfries and Maxwelltown held a very successful ball, which was attended by over fifty couples on Tuesday night, the 11th inst. It was opened by Mr. William Allan, local secretary to the Pharmaceutical Society, and president of the local association.

On Monday last, Professor W. R. Smith, Director of the Laboratories of State Medicine, King’s College, and President of the British Institute of Public Health, was the recipient of a testimonial—consisting of a silver salver, tea service, etc.—presented by the Lord Mayor, at the Mansion House, London, on behalf of a number of gentlemen interested in medical science, who wished to show their appreciation of the services he has rendered to forensic medicine and during the recent meeting of the Public Health Congress, of which he was president.
ELECTION OF ANNUNTIATES.

A General Meeting of the Members and Associates of the Pharmaceutical Society and Donors to the Benevolent Fund was held at the house of the Society, 17, Bloomsbury Square, on Tuesday, December 11, at 12 o'clock, for the election of four annuitants. Mr. MICHAEL CARTHEGNE, President, in the chair.

The notice convening the meeting was read by the Secretary, scrutineers were then appointed, who elected Mr. E. N. BUTT as Chairman, and proceeded to examine the voting papers.

On bringing up the report the Chairman said the Scrutineers who were duly appointed at the meeting for the election of four annuitants on the Benevolent Fund of the Pharmaceutical Society had examined all the voting papers which had been placed before them, and had unanimously agreed to submit the following report:

**Scrutineers’ Report.**

We, the undersigned Scrutineers, appointed at the thirtieth election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following result:

- Board, Thomas F. ...................................... 2616
- Bromfield, Charles ..................................... 4997
- Ellis, Elizabeth ........................................ 4834
- Kershaw, Ellen ......................................... 5581
- Troughton, Christopher .................................. 3625
- Watson, James B. ....................................... 5317
- Willson, Elizabeth A. .................................. 1541

4044* voting papers were received, of which number 73 were informal (45 unsigned, representing 172 votes and 25 incorrectly filled up, representing 66 votes).

**EDWARD N. BUTT, Chairman.**

W. PRIOR ROBINSON. ............................................. 2616
WILLIAM WARNER. .............................................. 4997
CHARLES J. MILES. ............................................ 4834
W. MURTON HOLMES. ......................................... 5581
R. FISHER YOUNG. ............................................. 3625
A. E. TANNER. .................................................. 5317
T. P. GOSTLING. ............................................... 1541
THOS. HENRY POWELL. ....................................... 4044
HENRY BAY. .................................................... 2616
GEORGE WYLD. .................................................. 4997
December 11, 1894.

THE PRESIDENT then declared the following duly elected Annuitants:

- Bromfield, Charles
- Ellis, Elizabeth
- Kershaw, Ellen
- Watson, James B.

The PRESIDENT moved a vote of thanks to the Scrutineers for their services, which was duly carried, and suitably acknowledged by the Chairman, Mr. E. N. BUTT, and, after a similar vote by the Scrutineers to Mr. BUTT for acting as Chairman, the proceedings terminated.

---

DONATIONS.

At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 12th inst., the Librarian and Curator presented the following report of donations to the Society’s Libraries and Museum:

**To the Library in London.**

DIREKTOR VAN A‘ LANDS PLANTSTUHL S TWINSEN:
Mededelingens uit Laards Planteskool, Nr. 11-12.
Smithsonian Institution, Washington:
U.S. Surgeon-General, Washington:
Index-Catalogue of Library, vol. 15.
Nova Scotian Institute of Science:
New York State Pharmaceutical Association:
Proceedings, 1894.
F. M. Bailey, F.L.S., Brisbane:
Queensland, Botany Bulletin, No. 9, 1894.
Philosophical Society of Glasgow:
Chemists' Assistants' Association, London:
Proceedings, 1893-94. Two copies.
British Pharmaceutical Conference:
Year-Book of Pharmacy, 1894. Two copies.
To the Library in Edinburgh.
British Pharmaceutical Conference:
Year-Book of Pharmacy, 1894.
Mr. R. I. Macdonell, Leith:
Photograph of Edinburgh Chemists' Trade Association Picnic Party at Norham Castle.
To the Museum in London.
Mr. S. Bithorp, London:
Specimen of Santolina chamomylaris, imported from France.
Messrs. Burgoyne, Burnbridge and Co., London:
Specimen of Malambo bark.
Mr. J. C. Wright, London:
Seeds of Megonia glabrata.
Messrs. F. H. Paulding and Co., London:
Specimen of the natural oil of Eucalyptus emorriola, rectified, containing 65 per cent. of Eucalyptol; standardised oil of the same plant, containing 50 per cent. of Eucalyptol; Phosphate of Eucalyptol, and chemically pure Eucalyptol; Resin oil left after rectification; heavy oil obtained from the resin oil; Oil of Eucalyptus siderata, and heavy oil separated from the residual resin oil after rectification; natural oils of Eucalyptus gono calyx, E. inorassata, and Melaenua uncinata.
The Imperial Institute:
Bark of Chiones glabra from Trinidad.
Mr. D. Greenough, London:
Specimen of Wheat thirty years old.
Mr. G. Curtis, Chislewick:
Photograph of fine specimens of Bryony root.

EVENING MEETING IN LONDON.

The second evening meeting of the Session was held on Wednesday, the 12th inst., when the chair was taken by the President, Mr. Michael Cartelgha.

The first paper read was by Sir Dietrich Brandis, K.C.L.E., F.R.S., on—

MEDICINAL PRODUCTS OF THE DIPTEROCARPIAE, an abstract of which appears at page 497.

Professor ATTFIELD, in proposing a vote of thanks to the lecturer, described Sir Dietrich Brandis as one of those rare men who observe accurately, and reflect and describe accurately. He had had opportunities such as had occurred to few men, and was thus able to give much useful information respecting the actual practice observed in the treatment of those trees.

Mr. Charles Umney, in seconding the vote of thanks, said that he had learned a great deal from the lecture. Now that students were studying the products of plants more than they used to do, the description given of the way in which the oleo-resin is formed in the different parts of the plant, and how the oil cells are divided, would prove exceedingly instructive. The tallow collected in bamboo tubes had been called attention to some years ago. It possesses the quality of melting at a very low temperature, slightly above that of cocoa butter, and it will keep for a considerable time without becoming rancid, besides having little odour.

The President recalled the fact that a distinguished member of the Society, the late Mr. Daniel Hanbury, who devoted the greater part of his life to original work in materia medica, had studied wood oils very closely. Such a lucid and helpful lecture as the present would have materially assisted the Major candidates, who in the old days were rather terrified at the prospect of an examination in the subject by Mr. Hanbury.

The vote of thanks was adopted unanimously, and Sir Dietrich Brandis, in acknowledging the resolution, said that the late Mr. Daniel Hanbury had proved that true scientific research and excellence in practice might well go hand in hand. The young men who studied in the excellent School of Pharmacy established by the Society should bear in mind that any moment they might in their researches hit upon some discovery of lasting importance. Possibly in the Dipterocarps there might be some substance which would be of importance in dealing with disease, and its discovery might be the work of one of the youngest students.

Mr. Joseph Ince then read the paper on—

"THE SAPHEIRISTA,

which is printed at page 499.

On the motion of the President, a vote of thanks was accorded for the paper.

Mr. E. M. Holmes then read his—

NOTES ON OPPONAX AND EUCALYPTUS OIL, which are printed at pages 500-501.

Mr. Payten said he had for nineteen months been engaged in the distillation of eucalyptus oils. He was not prepared to state the composition of the oils of the 180 different species existing in Australia, but he knew something of the composition of two of them. Many samples had been produced, derived from the different distillates and the various separated principles. The chemistry of eucalyptus oil was one which occupied a very large amount of attention, owing to the great difficulties attending the examination of essential oils generally as now known, but, for the first time, pharmacists were now given eucalyptol in a state of absolute purity, which could be prepared from the phosphate of eucalyptol. Unfortunately, there was an enormous amount on the market at present. One sample had been produced that night of eucalyptol, so-called which did not contain more than 75 per cent. of pure eucalyptol, and was deficient in its specific gravity. There were five or six other different kinds of eucalyptol. It was present in every kind of oil, the percentage being in every instance above forty-five and never above fifty-five in the samples examined by him.

Mr. Umney said that in the port of London eucalyptus oil seemed to be judged mainly by its odour. From the chemical point of view, it was well that they should be able to handle a substance of which they really knew something. They knew now that there was such a substance as eucalyptol, and that it could be separated by a number of processes. The old-fashioned process, which he had used in his laboratory, was to digest with caustic potash, rectify, and separate at a boiling point of about 175° C. The process described in the paper was very excellent, simple, and inexpensive, and, if it were true that it would give pure eucalyptol in the face of all that had been the process to go for. Personally, he rather objected to a standardised eucalyptus oil, because it was certain to vary; the eucalyptol might be constant, but there would remain the varying odours; it would be preferable to keep simply to eucalyptol. Mr. Umney then referred to the report on this subject from Australia, recently appearing in the Pharmaceutical Journal, and said that the solid substance or gum obtained from the eucalyptus was undoubtedly valuable, but he was not prepared to say whether rectified eucalyptol had the efficacy attributed to it, from a medicinal point of view. In fact, one could not help, in reading this correspondence, suspecting that one good friend the colonists had their own axe to grind in seeking to put eucalyptus oil into the Pharmacopœia.

Mr. Allen remarked on the differences in the physical characteristics of the various eucalyptus oils. According to his experience, no single thing in the Pharmacopœia caused so much trouble to the pharmacist in the compounding of remedies as eucalyptol oil. It would be a good thing if we could either deal solely with eucalyptol, or with some standardised oil that would have at least an approximation to a general characteristic odour.

The President said that it was a considerable step to have got something as definite as eucalyptol, and, when experiments had been made upon it with oxidising and reducing agents, still more satisfactory knowledge would be acquired. He believed that a very large part of the therapeutic effect, whatever that might be, was common to not only eucalyptol but a number of other oils. He proposed a hearty vote of thanks to the reader of the papers.

Professor Attfield, in seconding, said that, as a chemist and a scientific man, he welcomed eucalyptol, but, as an editor of the Pharmacopœia, he considered they had not as yet very definite information about the new article. So far, pharmacists and chemists had done even more than could have been expected of them in connection with eucalyptol oil; they had gone ahead of the therapists, and the next movement ought to be made by the medical profession.

The resolution was carried unanimously.

Mr. Holmes, in returning thanks, said the main object of his paper was to show that in eucalyptol there was a definite subject for pharmacologists to deal with.

The proceedings then terminated.
Proceedings of Societies in London.

CHEMICAL SOCIETY.

A meeting of the Chemical Society was held on Thursday, December 6, the President, Dr. Armstrong, F.R.S., in the chair. The following papers were read:—

THE USE OF THE GLOBE IN THE STUDY OF CRYSTALLOGRAPHY.

BY J. Y. BUCHANAN, F.R.S.

The author described the use of the globe in the study of crystallography, it being so arranged that lines and geometrical figures could be traced on the surface and the globe rotated in any direction; then by suitable means the lines obtained projected on to a plane surface.

Lantern slides were then shown by Miss Walter and Mr. Bourne, and described by the latter, of an apparatus exhibited at the conversations of the Royal Society for applying the above method to the actual measurement of crystals.

The next paper was on

THE RELATIVE BEHAVIOUR OF CHEMICALLY PREPARED, AND OF ATMOSPHERIC, LIQUID NITROGEN.

BY PROFESSOR DEWAR, F.R.S.

When gases, such as nitrogen, oxygen, or air, are liquefied in large quantities, the impurities present in the gas interfere with investigations on their relative behaviour at low temperatures. When liquefaction occurs, the impurities—which may be water, carbonic acid, or organic vapours from the pumps—accumulate, and ultimately are found admixed with the liquefied gas in the solid state. When the impurities, which may amount to 1 per cent. in liquefied air, separate as a solid, filtration may be used to separate the solid from the liquid, but this method does not give a perfect separation owing to the difficulties in filtration at such low temperatures. If smaller quantities of gas as previously purified by chemical methods are used from a gas holder, by the use of rubber tubes, tanks, etc., the traces of moisture are found which cause opalescence on liquefaction and thus vitiate results. By the use of a special apparatus, however, small quantities of perfectly pure and dry gases may be examined, and, furthermore, the experiment repeated as often as desired with the same specimen of gas.

The apparatus used consists of an ordinary distilling flask with a side tube. A capillary tube is sealed on to the mouth of the flask, and bent so as to have the free limb parallel with the neck of the flask. The flask containing phosphorus pentoxide is first exhausted, the pure gas introduced under known conditions of temperature and pressure, and the flask then sealed. In order to examine the relative behaviour of two gases at low temperatures, two flasks are taken, filled with the two gases under similar conditions, and the capillary tubes are inserted through a cork into a vessel containing liquid oxygen. This vessel is then partially exhausted, the oxygen begins to boil off, a reduction in temperature ensues, and the behaviour of the condensed liquids in the capillary tubes is carefully noted.

In this way any two or more gases can be compared, and the temperatures noted at which they liquefy, as well as their behaviour on suffering fractional distillation when the temperature is raised.

During this liquefaction in the capillary tube there is a reduction of pressure in the flask, and this might be measured by attaching a manometer to the side tube of the flask instead of sealing off.

If, however, such liquid gases are always compared with oxygen and the variations in the vapour pressure determined there is no need for the attachment of a manometer. Knowing the pressure at which the gas is introduced and temperature of liquefaction, it is possible to calculate the pressure by drawing the curve of vapour pressure, and comparing with oxygen, and in this way we obtain the vapour pressure of the liquefied gas at the given temperature is obtained.

When pure nitrogen (either made from air or from various chemical compounds) and pure oxygen were examined by this method, no solid was obtained, proving that the substance obtained from air must be an impurity. Nitrogen made by the ordinary method of passing air and ammonia over copper always contains oxides of nitrogen.

An examination was now made of nitrogen obtained from different sources, that had been passed over hot magnesium which would combine with some of the nitrogen and either give up a gas as impurity or not absorb any impurity in the nitrogen.

By this method experiments were made on nitrogen from air, and nitrogen from ammonium nitrite, nitric oxide, or which had been passed over hot magnesium.

The residual gases appeared to behave almost exactly alike on liquefaction, the nitrogen from the air liquefying at a slightly higher temperature than the other samples. The difference is, however, extremely small. The conclusions, then, point to one of three possibilities:—

(i.) The nitrogen from the air contains no marked impurity of higher working point than nitrogen.

(ii.) Nitrogen, and the impurity or other substance contained in nitrogen from the air, have the same boiling point.

(iii.) The impurity does not liquefy at 200°.

With this apparatus it is also possible to examine gases under different pressures, and to observe the liquefaction of air, when it is found that the oxygen liquefies at about 1° above the temperature of liquefaction of nitrogen.

The next paper described a

NEW METHOD OF PREPARING DIHYDROXYTARTARIC ACID.

BY H. J. H. FENTON.

In continuation of his previous researches on the oxidation products of tartaric acid by hydrogen peroxide, the author found that dihydroxytartaric acid is easily prepared by oxidising tartaric acid by bromine water and acetic acid. He also proposed to make use of the sparing solubility of the sodium salt, as a qualitative test for sodium. The acid is dissolved in water, and, on adding a weak solution of a sodium salt, a white crystalline precipitate is produced.
he last paper was on—

ESSENTIAL OIL OF HOPS.

BY A. C. CHAPMAN.

Further investigation of this oil shows that by
fractional distillation under reduced pressure three
products are obtained:—
(I.) A hydrocarbon giving figures on analysis for
formula C_{10}H_{15}, but which is probably a mixture of
hydrocarbons of formula C_{10}H_{14} and C_{10}H_{16}; the latter
being probably a tetrahydrocyrene.

(II.) A very small fraction of hydrocarbon C_{10}H_{17}.

(III.) The sesquiterpene, C_{10}H_{14}, before described
(Proc., 83, 177), which does not appear to be identical
with any hitherto described. It contains two dyad
carbon atoms, and yields a crystalline compound with
nitrosoyl chloride, and an unstable hydrochloride with
hydrogen chloride. The physical constants obtained
were in accord with above conclusions.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting held on Thursday, December 6, a
paper was read, entitled—

CAN WE STOP "COMPANY" PHARMACY?

BY H. R. CARR.

It was pointed out that the present state of
affairs with regard to the competition of stores had been
foreseen as long ago as 1889, but, in spite of all
attempts to thwart it by those who saw the danger, it
had steadily grown, and been fostered in many
cases at the hands of pharmacists themselves, who had
taken up "cutting" without being in any way compelled.
The greatest attempt against it had been made by the
Pharmaceutical Society in the famous prosecution of
the London and Provincial Supply Association; and
the result of that and other cases had shown that the
pharmacist was only privileged with respect to the
twenty-six articles in the Poisons Schedule, and that
the law gave no monopoly in the sale or compounding
of even these, caring only for the safety of the public.
Nor could it be shown that safety was less ensured in
the pharmacy of a company than in that of any
individual pharmacist. All that could be done to
obtain fairer legislation would be to ask plainly for
greater privileges; but the hope from this was frail,
as so few were in sympathy with the pharmacist,
many people even now believing that his average
profit was ninety-nine per cent. It was suggested that
there were only two ways of making company phar-
macy impossible—one, by controlling the supply of
drugs; the other, by forming a trade union of all the
chemists on the Register. Experience had shown
that it was impossible to carry out the former method,
while, as to the latter, even supposing that ninety per
cent. of all qualified chemists joined a trade union,
the only result would be an easy opportunity to the
remaining ten per cent. to make their fortunes.

In the discussion which followed, most of the mem-
bers agreed that the pharmacist of the future would
have to depend on the confidence he could inspire in
his personality.

At the meeting held on Thursday, December 13, a
paper, of which the following is an abstract, was
read:—

THE FUTURE OF PHARMACY.

BY H. A. D. JOWETT, B.S.C.

Pharmacy at the present time occupies an anomalous
position which forbids all comparison or analogy with
any other trade or profession. It is both a trade and
a profession, and this combination at present yields
unsatisfactory results. The pharmacist has to face
and meet the competition common to all trades, and
at the same time to render professional services which
require the application of varied knowledge. As a
result, he is viewed by the public as a tradesman,
and his remuneration is fixed accordingly. That this
is so is proved by the status of the men attracted
to pharmacy, by the social status of the phar-
macist, and by the pecuniary inducements held out
in to assistants.

The present unsatisfactory condition of pharmacy
may be referred then to two causes. First there is
that arising from the trading part of pharmacy; here
as in other trades the pharmacist is subject to the
keen competition due to the present state of over-pro-
duction and unequal distribution of population and
wealth.

Then on the professional side the causes are many.
Dispensing is now frequently done by doctors them-
selves, and sometimes it happens that in addition to
dispensing the doctor sells such articles as chest
protectors and proprietary medicines. Then there is
the excess of supply over the demand for pharmacists,
and lastly, but not least, the incompetence of the average
pharmacist himself. He is not, as a rule, educated
up to a professional standard, and consequently the
public judge accordingly, classify all pharmacists from
the few they come in contact with, and the result
is that they occupy a similar position in the public
esteem to a grocer or draper. Advertisements for
a dispenser whose wife will cook and attend on the
medical officer, or offers of the magnificent salary of
£104 yearly to Major men, only prove conclusively
that the pharmacist is not viewed as a professional
man, and his remuneration is fixed accordingly.

Then how will these causes affect the future of
pharmacy? In answering this question we must
divide it into two headings—(1) the future of
the trading part, (2) that of the professional side. With
regard to the former, there can be little doubt
that the day of the small tradesman is past. In
future we shall see further developments of the store
system, then these will be brought into competition
with each other, and ultimately they will probably
be taken over by the nation and managed by them
as gasworks, waterworks, &c., are now managed.
In the case of trading, pure and simple, it is obvious
that the fittest in the struggle will be those with
the greatest capital and turnover, and they accord-
ingly will survive.

On the professional side, however, the personality
of the pharmacist must for ever be the most potent
and the determining factor. His services will be in
requisition, and his remuneration determined by the
amount of confidence reposed in him by the public
There is always a demand for the best advice, and here the individual is master of the situation, and only on this side is there any hope for improvement in pharmacy. But if the future pharmacist is to attain this position he must recognize as the outset that he is entering a profession and about to incur all the risks attaching thereto.

He must be prepared to go through a long course of training and to acquire very varied experience before he can hope to make a bare living, and according to the time spent in the acquirement of such knowledge and the power of applying such, so will he possess the confidence of the public and be likely to succeed in life. He must possess a much better general education than is required now, and above all he must learn to adopt professional methods; he must not cover the rocks and country side, or even Nelson’s monument with advertisements. Such procedure may be legitimate trading, but it is not professional.

In fact, the future pharmacist, if he is to maintain his individuality and not become a servant of a limited company, must “become a scientifically educated technical expert entitled to professional fees for his professional services.” “He must be equally well prepared for the best professional service at the prescription table, to aid the physician as the chemist of the medical profession, to act as public analyst, to undertake the work of the manufacturing laboratory, or for any related technical pursuit.” He must, then, retain all the professional element that he now possesses, and, in addition, regain much purely professional work, such as analysis, which has slipped away from him owing to the incompetence and lethargy of former pharmacists. But here let me warn you that you will come into competition with another body of chemists who, differently trained, are nevertheless equally competent to undertake similar work as analysts.

It may be urged that this kind of work is limited, that the supply is already in excess of the demand, and that may be so; but what trade or profession is not overcrowded? All depends on the individual himself. There is always room for the best; and the leaders in any profession, be they chemists, doctors, or barristers, are overloaded with work, whilst the struggling crowd of mediocrity have none.

Finally, does future legislation hold out any hopes for the future pharmacist? I think it is quite certain that you will never be able to stop company pharmacy, nor would it be just, so long as companies employ duly qualified men. The number of scheduled poisons may be extended, but one can hardly look on the selling of poisons as professional. Dispensing will, I am afraid, continue to be done by doctors, for there are many people who cannot afford to pay both doctor and chemist. The title may be protected, for it is possible that legislation will be enacted for the proper use of all scientific titles, and the chemist might well be included.

What, then, will be the position of the future pharmacist divorced from trade?

With pharmacy recognised as a profession, requiring a long course of study in the attainment of proficiency, and constant new application of knowledge already gained, those who follow it will be respected by the public, and may then hope to obtain professional remuneration for their services. The physicians will recognise in the pharmacist a fellow-worker in science, will regard him as a helper, and we shall then see more cordial relations between these closely allied professions.

Lastly, but not least, with increase of professional spirit we shall see the death of that petty jealousy so general amongst us nowadays; we shall see pharmacists banded in a society, the present one, I hope, but greatly increased in numbers, striving not only for self-protection, but for the furtherance of knowledge amongst themselves, and thus in the application of such will there be advantage to the human race.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting was held on Thursday, November 29, H. T. Durant, vice-president, in the chair. A paper on the history of the word “Chemistry” was read by C. S. Ellis, who gave several possible derivations, among which he instanced Chemis as the tradition relating to the art taught by the sons of God to the daughters of men before the deluge; from this it came to be more particularly applied to the art of making gold. An ancient name of Egypt was Chemis, on account of its black soil, and the word was also used to designate the pupil or black part of the eye; hence it may have come to signify the black or mysterious art. The Arabic Kema, to hide, and the Greek Theo, to melt, or Chymas, juice, were also given as very probable origins. Whatever the original root may have been, it came to us through the Arabic, as shown by the prefix al, which was used with it during the Middle Ages. A discussion followed, in which the Chairman, Secretary, Messrs. Maunder, Read, and Goulding took part.

A paper on Sugar was then read by Sidney Davis, who gave a full description of the manufacture of sugar from the sugar-cane and beet, and the processes used in refining; other commercial sugars such as glucose and sugar of milk were also treated of more briefly. The paper gave rise to a discussion, in which the Chairman, Messrs. Read, Moore, Smith, and the Secretary joined.

The Secretary announced that the Executive Committee had appointed the following Reporters on Science:—Pharmacy, W. Moore; Botany, R. Goulding; Materia Medica, C. J. Taylor; Physics, H. T. Durant; Organic Chemistry, C. S. Ellis; Inorganic Chemistry, A. T. Hill; Analytical Chemistry, R. G. Gwyer.

The meeting then adjourned.

SMOKING CONCERN.

The annual smoking concert of the football and cricket club in connection with the Association was held in the concert hall at the Holborn Restaurant, on Tuesday, December 11.

Professor J. Reynolds Green, Dean of the School of Pharmacy, occupied the chair, and was supported by Messrs. C. B. Allen, Alexander Bottie, Thomas Greenish, and Walter Hills, members of Council; Professor Greenish, Dr. Harding Bremridge, Dr. Inos, Messrs. Bateman, Birn, Richard

* Dr. O. Oldberg (Pharm. Journ., ante, p. 211).

Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

At a meeting on Thursday, 15th inst., Mr. Jas. Robb was called to the chair, and the following paper was read:—

ALL ROUND THE B.P.

BY ALEX LAING.

For the first time in the history of pharmacy, pharmacists are afforded an opportunity of airing their opinions on those substances and preparations the medical profession is desired to recognise as standard medicines, which it is chiefly their duty to make ready. It is a responsible position, for it is not our province to know the influence of drugs upon the system, and how we are to offer an intelligent view unless such knowledge is allowed it beats me to understand. In doing that, as I intend just now, I am content to hide myself as a pharmacist, and touch the different points as a spectator who has some interest in the rise and progress of the art and practice of medicine from an increase-of-general-knowledge point of view, and my observations carry no weight but such as my appeal to the sense of those who are the judges.

There are some statements I feel called upon to make, quite apart from the Pharmacopoeia, yet more important than what I have to say with reference to it, for we have duties in respect to the public generally as well as to the medical profession, and though it sounds nice to hear it said, "the public must be protected," I would like it to be shown that it is entirely honest. I hold the same opinion as Dr. Johnson, who was a metaphysician, that a man of forty years is either a fool or a physician, inasmuch as by that time he ought to have an intelligent perception of the functions of the organs in the human body, and he ought to know what is hurtful to himself. The use of drugs gets beautifully less amongst the more intelligent classes in the community, while the abuse of drugs, kindly fostered by the laws relating to patent and proprietary medicines (save the mark!) grows beautifully greater. And any effort made to educate the public towards a definite standard combination of drugs for a definite purpose is directly frustrated by the Board of Inland Revenue. Even pecos. and squills, recommended for a child's cough, would be "liable to stamp duty." It should be our duty, and the duty of the medical profession as well, to stamp the other duty out, and I wish the medical profession would read some of the pamphlets relating to these patent nostrums and learn from them what influences the mind or imagination can have in persuading ignorant people to get well when a gentle stimulus to the bowels or kidneys is given. But for their ignorance they would not have been reduced to such wrecks as their testimonials make them; and either we should endeavour to dispel that ignorance, or they should die right off, and save humanity from the quacks and charlatans who thrive on its fears and credulity. The 'Family Physicians,' written for the public by eminent medical gentlemen, are hardly so mischievous, because in serious cases or in symptoms of fever they are not relied upon. But they are useless for the purpose of instructing humanity or the heads of households in those simple preliminary attacks of illness that may mean anything or nothing—in which a stitch in time may save nine. Accounts of the courses of fevers are not for family application, and may mislead more than help.

I think, too, some remarks on the bacteria find, which is so much with us at present, will not be amiss. Bacteria we have had always with us, and, taken all in all, they are not only harmless but purifying, inasmuch as living organisms are better than putrid matter. With a healthy mind in a healthy body, the deadliest microbes can get no hold; and in surgical cases the process of healing is from within, therefore the first aim should be to strengthen the system. Possibly the daily press misrepresents the medical profession in the wretched attempts it makes to inform the general public of scientific researches in the world of medicine, but the authorities from whom the information is derived ought to study their words and use them with strict regard to their legitimate meaning.

Just now there is great activity in experimenting with serums and glands from each and every part of the animal economy, and injections of these are to work a revolution on the body of a long-suffering humanity. It is to me a disgusting piece of folly, which I would infinitely prefer to die rather than submit to and live. Let us learn to eat pure, and drink pure, and breathe pure, and think pure, and all these serums and condensed animals and animaliauses may be sent to the British Museum to show future generations what stupid and abject methods were prosecuted to prolong life.

Under present conditions we cannot expect the highest service from the individual physician, as the "first law of life" claims too much attention; and until that is remedied by making him an official in the State, a pariah doctor, in se nescio, not much progress will be made in educating humanity how to keep well and die gracefully.

My remarks directly on the B.P. are only of a general character, as several opportunities will be afforded during the session of approaching it more closely.
I would like, in the next B.P., a better recognition of apothecaries’ weights, even to replacing the present avoidurops in tintuaires, and every other preparation.

It would be well, as an introduction to the metric system, to put the alternative quantities in grammes and litres. With the solutions of strychnine, etc., altered from 1 grain in 2 fluid drachms in the previous edition to 9 grains in 2 fluid ounces, I have never felt sympathy, as our standards of measure were more in accord with the 1 in 120 solution. I remember several letters appearing in the Journal referring to a deposition of crystals in lig. strychnine, which I could only account for by assuming that the alternative quantities in parts were the source of an error; one part of strychnine being taken as one drachm, instead of one eighth of an ounce. With the metric system that could not happen.

The pills in the B.P. seem to be there for an illustration of what to avoid in prescribing, as they are more honoured in the breach than the observance. They are generally too big at five grains in each, and only pil. rhei, or, ruined in shape by glycerin, and pil. colocyntum et hyosc, with ext. coloc. co, preferred to mass pil. coloc. co, have much attention paid to them. A mode of coating should be approved by the Medical Council, and that suggested and used by Martindale is simple, efficient, and elegant.

Infusions in a concentrated form would be an advance; macerating at first with water containing sufficient spirit to preserve the finished product; percolating until a certain quantity was collected to be set aside; the marc exhausted with water; and the percolate evaporated, until, on being added to the spirituous percolate, the desired quantity was made.

Tinctures also should be made by macerating in sufficient spirit to exhaust the various ingredients of their active virtues, and percolated until, having ceased to drop, the last of the fluid can be expelled by water to make the requisite bulk. In these days of total abstinence and liquor traffic agitation, we could assist the community by adopting the happy medium of reducing the quantity of spirit to the least necessary, and at the same time circumvent the increased duty on spirits inflicted upon us by a grandmitherly government. With rectified spirit tinctures, such as cimicifugs and myrrh, we would soon know to a nicety how much could be expelled from the marc before the water mingled, and sufficient spirit added before the water would entirely do away with the tincture press.

I hope the coming B.P. will give us a series of syrups to redeem us and the medical profession from the legion of “distinctions with no difference” we are obliged to keep to suit the idiosyncrasies of different prescribers, including a syrup hypophosphites co, and Easton’s syrup. Both of these are troublesome to the retail chemist, but I hardly approve of the public being supplied on demand, especially with the latter. Containing strychnine, they come under the first schedule of the Poisons Act, but if made with an equivalent quantity of nux vomica extract, they would fall under the second, and a simple poison label fill all the claims of the law; besides, the colouring matter in the nux vomica would disguise the iron oxidation which makes Easton’s syrup unsightly on keeping any length of time.

Pulv. rhei co. should be recognised made with heavy calcined magnesia as well as light. Pil. plumbi co o, and all the horrid astringent tintuaires and powders of the catechu calibres, should be blotted out as relics of a barbarous age.

If the object of negative tests is indicated in the future by the words “absence of so-and-so” it will be of great assistance to budding pharmacists; and some negative tests, especially of oils, would not be amiss.

Finally, here is a list of things I would like omitted as affect relics of barbarism, which I would part from without one tear of regret:

All synonyms excepting “cream of tartar,” sal ammoniac, and for theaicea, golden syrup.

The Chairman, Mr. Robb, in inviting members to give their opinions, said Mr. Laing’s idea would commend themselves to students generally, and there would not be much of the B.P. left if his advice were followed.
Mr. Boyd considered that the study of bacteria was likely to increase. He mentioned the decrease of the death-rate in hospitals since the introduction of the antiseptic treatment. Treatment by glands was a new production, but castor, which was dropped in the last B.P., was still in use, and he had dispensed it recently. Extract of thyroid gland, and of the suprarenal capsule were used with good effect in cases of myxoedema and Addison's disease, but it was a question more suitable for doctors to decide. Enemata of asafetida and turpentine were still in use. In pills we might have a useful formula for pil. phosph. co., which was often prescribed. There was a superfluity of syrups, such as mulberry and hemidesmus and an absence of syrups very much prescribed. The change in the strength of the liquors of the present B.P. was not a good move. It was easier to remember 4 grains to the ounce, and easier every way. Dropping Troy weight had complicated matters, but the metric system was not so good as avoirdupois. It was easier to write grains ½, ½, than the Chemists, as the mind could better grasp a vulgar fraction.

Mr. R. Brodie was averse to discarding preparations from the list, as he liked to have the formula of anything in demand convenient to his hand. He also disapproved of the metric system, and was in favour of Troy weight.

Messrs. Russell, Bruce, and Blair also took part in the discussion, and, in concluding, the Chairman asked for a vote of thanks which was unanimously acceded.

**PROVINCIAL TRANSACTIONS.**

CAMBRIDGE PHARMACEUTICAL ASSOCIATION

A very successful smoking concert was given by the members of this Association and their friends in the Alexandra Assembly Rooms, Cambridge, on Friday, November 30. Mr. Alderman D. acted as chairman, and there was a very interesting programme, in which Messrs. R. Ope, A. A. Walker, H. T. Wing, Markham, F. Dale, E. T. Rider, A. R. Hill, E. H. Church, H. Clare, P. S. Campkin, W. L. White, H. Bryan, and A. Plumb took part. At the conclusion of the programme, most of the performers having been encored, votes of thanks were passed to the chairman and performers, especially to Mr. E. H. Church, who had arranged the concert.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.

JUNIOR SECTION.

The monthly meeting of the above was held at the Foresters Hall, Octagon, on Thursday 6th inst., at 8.30 p.m. Among those present were Messrs. F. A. Goodwin, Chairman, H. O. Westcott, Secretary, Wood, Fisher, Newman, E. T. Cocks, Whitlock, Dentney, Hodge, Darke, Downing, Fairweather, Barber, and Burden. The members regretted receiving the resignation of Mr. A. Goodwin, who had so ably filled the chair, and was leaving the neighbourhood. Mr. E. H. Newman was elected to occupy the same. At the conclusion of the general business, an interesting paper on "Volumetric Analysis" was read by Mr. F. A. Goodwin and illustrated by experiments. He estimated Hg, soda ash, etc., at the close a vote of thanks to the author was passed for his instructive paper, proposed by Mr. E. H. Newman, seconded by Mr. R. A. Hodge.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

A meeting of the Manchester Pharmaceutical Association was held on Wednesday, December 12, at the Victoria Hotel, Manchester. Mr. G. T. Woolley presided, and the attendance was large.

The President, in introducing Mr. Taylor, mentioned that there was with them this evening Dr. Paul, editor of the Pharmaceutical Journal.

The following paper was then read:

**A PHARMACEUTICAL WANT LIST: AN ADDRESS ON TRADE TOPICS.**

BY JOHN TAYLOR.

The list I lay before you I have compiled myself. It does not profess to contain all the things we want, nor are you to infer anything as to the relative importance of the items from the places they occupy on the list. In considering our wants, I speak, of course, primarily for myself. Still, I think I shall voice the sentiments of many pharmacists, both present and absent. I cannot claim novelty for any of the topics, or newness of treatment either. I only ask you to believe that, in responding to the call of our Secretary for an article on trade matters, I have a sincere desire to aid in the supplying of our wants.

Our first want is a stringent first examination. I shall not say much on this question as you discussed it at your last meeting. But I wish to notice the objection usually raised to an alteration of the Preliminary. It is said the prospects of the drug trade do not warrant the mental and monetary cost of a severe first examination. The trade is "not worth it," is the phrase used. That, I submit, is a view of the matter which concerns us who are in the trade very little.

It is, however, a point well worth the consideration of those who wish to enter the trade. Our object is to lessen by all fair means the number of qualified competitors we must meet. Not only that, but to secure that all who do come in shall have reached an educational status which will do justice to, and bring honour upon, the pharmaceutical body.

The existence of a well educated, highly skilled body of pharmacists may not necessarily lead to increased profits or lessened outside competition; but I am convinced that if the education and mental calibre of the body of pharmacists does not command public respect we shall never get the public to meet such of our wants as can only be met by legislation.

We want equality in membership of the Society. At present, as you know, the Council of the Society (its legislative and executive body) consists of twenty-one members. These are elected by a constituency in which obtains the principle of "one man, one vote." So far all is well.

The suggestion that the members who retire annually should do so in rotation instead of by ballot is a good and sound one. In matters of this kind nothing should be left to chance.

But whilst there is equality of voting power and subscription paying, there is a difference of status as regards other things, notably as to membership of the Council. Two-thirds of the Council must be pharma-
ceutical chemists, the other third being chemists and druggists. The inequality is greater than at first sight appears, for the third, consisting of chemists and druggists, must be men who were in business when the Act of 1868 was passed. So then, whilst the youngest pharmaceutical chemist on the Register is eligible for the Council if he subscribes, it is, as regards chemists and druggists, a case of “no young men need apply.”

This is a grave inequality. The number of chemist and druggist members is constantly dwindling, and time alone is throwing the affairs of the Society into the hands of the pharmaceutical chemists entirely. So you have this state of things—that a large number of subscribers (considerably over one-third of the whole) have no right to sit on the Council. They pay a subscription equal to that of any member of the Society, but are denied any direct representation on the Council. This is neither fair nor wise. It is unfair because, where all pay alike, there should be disabilities imposed on none. It is unwise because disqualification invariably brings on discontent or indifference, or both. It bars out every Associate, no matter how able or willing he may be to serve on the Council. Whatever a man’s qualification may be—if he has lacked time or money or ability to pass the Major—he may not aspire to a seat on the Council unless he was in business in 1868—that is, unless he has probably seen the best of his days. A trade union which reserved a majority on its executive body to one section of its members would soon cease to exist, and rightly so. A man will serve his fellows with more zeal if he has an outlet for his ambition, surely a laudable one when it leads him to serve his brother-craftsmen. We Associates are denied that outlet for our ambition, if we have it. Our part is strictly limited to payment and criticism. Under such circumstances the criticism is apt to become harsh and unreasonable.

I feel confident that until our Society is put on a thoroughly democratic basis, as well as to qualification for office as to voting power and subscription, we shall meet with discontent and apathy on the part of the trade.

Here let me anticipate possible criticism from pharmaceutical chemists. I would not have gone so much into this question if it had not been that I know many Major men are jealous of any interference with present arrangements. It is not the title of pharmaceutical chemist we want. There may be on the part of some a desire to place those initial letters after their names. I am not of the number. I do not care the proverbial “tinker’s curse” for the title of Ph. C. or any title which I have not earned in a fair and legitimate way. If as a “man” I have not a right to a position, I do not want it on any other ground.

What I want—may I not say what we want—is not title, it is the reality of power. We can have that without robbing any man of his rights. We want to meet, as regards the working of the Society, on perfect equality. Equality of subscription, equality as members, equality in having the right to fill any office to which the constituency may think it proper to elect us. Give us these things, and, as regards titles of honour and merit or scholarship, let them go to the men who honestly earn them.

You will gather from this that I do not think the pharmaceutical chemists have a prescriptive right to any given number of seats on the Council. I do not. Their title always being safeguarded and maintained as an honourable distinction, I do not see that they have any rights or interests superior to those of the humblest associate in business. I recognize only one title to a seat on the Council—that given by a majority of votes. I believe that if this principle of equality had obtained all along, much of the difficulty, indifference, and discontent on the part of the trade would never have been met with.

Another thing we want is the power to remove a chemist’s name from the Register. As registration bestows certain privileges (not worth much just now) on a man, it is only fair the public should have some guarantee that these privileges shall be rightly used. It is fair, too, that a man’s colleagues should have the right to expunge his name from the trade roll if he act treacherously towards, or disgrace his calling.

A power like this would need to be safeguarded and used judiciously. The Legislature, if it grant us this power, will see to that.

We have already power to expel a man from the Society; it needs to be supplemented by power to remove his name from the Register.

One or two local associations have banded themselves with drafting a code of pharmaceutical ethics. They may spare themselves the trouble. If they will help us to get this want supplied, then round the power to expel a man from our Society, and to disqualify him, or suspend him from practising as a pharmacist, a code of ethics will soon begin to grow.

The next of our wants I shall notice is one on which there is probably greater difference of opinion than on those last noted. It is the dividing of the constituency into districts. At present, in electing a Council, the subscribers to the Society vote as a single constituency. The result is that we all vote more or less blindly as regards the candidates. Thickly peopled cities like London, Birmingham, and Manchester, can always put in their man. To get that result, they often have to forego voting for any other candidates, however good they may be. Only a comparatively small portion of the electorate vote at all, the rest care too little about it. They have come to feel it makes little difference.

Now, without attempting to draw up any scheme of district representation, let me point out its advantages. If the country were divided into, say six districts and a representation of Councilors allotted to each on some fair plan, it would be possible for candidates to get personally into touch with their constituents. At a small expenditure of time and money, the candidates could address meetings of the trade in a few centres. This, by interchange of opinion, would enable the voters to form a fair estimate of the qualifications of the man who sought to represent them. The candidate, on the other hand, would get a first-hand knowledge of the wants of the trade, as such wants are felt
by business men of a class different from his own. I think man would soon cease to be apathetic as to who represented them, when they found that their members were to be got at and conversed with.

But there is an advantage about electoral districts which outweighs this. You well know that when a man gets on the Council it is a matter of the utmost difficulty to get him off again. This point was touched on at your last meeting. Apart from any question of libel, it is a disagreeable thing to have to object to a man whom you never saw. At present, it can only be done in a way that creates a suspicion of personal bias and jealousy, which, as likely as not, will defeat the purpose in view. When a man can only be attacked by circular or letter to a trade journal it is a most invidious task to attempt. His conduct as a Councillor may be fairly open to discussion, only there is at present no fair means of discussing it. It is not necessary to suppose the candidate guilty of any low or mean or reprehensible conduct. He may simply not be a good representative, or he may neglect his duty. The result is the same in each case.

No fair opportunity is given to call him to question, and anything like concerted action is impossible. Now I contend that if we had district representation this difficulty would disappear. A man who had not the confidence of his local fellow-tradesmen would have no other voters to return him. It would soon lead to all Councillors following the good example of our excellent representative, Mr. Young, in giving a more or less formal account of their stewardship. I need not dilate on the consequences of contact like this between voters and representatives. It would not usher in a golden age of pharmacy, but I firmly believe it would do much to make us more at one in our common interests.

It would certainly give us a just and easy way of getting rid of undesirable men; for, knowing them and being able to meet them at trade gatherings, we should be able to do our work of question or criticism without on the one hand, being exposed to the dangers of public letter-writing, or on the other hand exposing the Councillor or candidate to public contempt.

Again, I think district representation would give us all the advantages of the projected Federation of Pharmaceutical Associations without the disadvantage of duplicate organisations. I sympathise much with the objects of those who promoted the Federation. But I think it a waste of energy, and little likely to succeed. The Federation will probably never become sufficiently definite and compact to do any work. Even if it did, for want of a body within reach on which to place its blows it will effect little. If it could get at Councillors or candidates it might do something, but it cannot. The size, and if I may use the term, the amorphous properties of the constituency absorb its efforts and nullify them.

Another of our wants is, some alteration regarding the sale of poisons.

The schedule wants extending and re-arranging. I am not going into the carbolic acid question. That is a public want even more than a pharmaceutical one. The point I shall briefly note is this—that at present the principal restrictions on the sale of poisons are rightly placed on the retailer. To those restrictions no reasonable pharmacist will object. But this question has arisen in my mind, are there sufficient restrictions on the wholesale sale of poisons? At present there are none except the labelling with the name of firm, name of article, and word “poison.” I do not think these are sufficient. Plainly, I think it should be illegal to supply poisons wholesale to persons not on the medical or pharmaceutical registers. Exceptions would of course, be made in the case of hospitals and manufactories, large or small. What we want is to stop the supply to herbalists and unqualified traders, who can only want them for illegal sales. There are many wholesale houses who will not open accounts with any unregistered men. There are many who not only open accounts with them, but actually canvass them for orders. These houses are assisting them to break the law whenever poisons are supplied.

I am well aware a clause like this would give rise to much dispute, and would be difficult to enforce. It could be enforced, however. I think, too, that those houses who are loyal to the retail drug trade would welcome it, for it would help them against the competition of men of easier principles. You know what Government can do with a clause like this in the case of methylated spirit. It could do as much with our help, with a poisons clause drawn up on like lines. Of course, the analogy of methylated spirit holds good only up to a certain point, and there I must leave it for the present.

The next is perhaps our biggest want. It is the abolition of company pharmacy.

I am sure I do not need before this audience to discuss the fairness or justice of company pharmacy. I shall term it unjust to the individual pharmacist. It is from the point of view of its injustice that I shall deal with it, for it is that aspect of it that appeals most strongly to me. I care little how fierce the competition I have to face from a private firm of pharmacists or a brother trader qualified like myself. If in the struggle I go down, I can at least go down knowing that no unfairness has directed the blows that slay me. No sense of injustice will embitter my pharmaceutical end. But it is otherwise with the competition of a limited company. In that case I am fighting dividend-hunters, or what is really an unqualified trader who has taken into partnership “his sisters, his cousins, and his aunts.” It is the sense of the injustice of this kind of trading that galls me.

Now, can this want be met? If so, how? It will be difficult to destroy company pharmacy, that goes without saying. It is in possession. It represents in some cases large vested interests. It appeals to the public pocket, an appeal always listened to attentively. So that there is a hard task to be got through before we get what we want here. Because the task is great, are we to sit down and say “it is done and we cannot undo it?” That may be your opinion, it is not mine.

The very first thing we have to do is to create all through the retail drug trade the feeling that com-
pany pharmacy is to be fought. We must fight it and not give up the fight until we are thoroughly beaten in Parliament and have made sure that we are beaten. There should be no backsliding on this point. Some wholesale houses and large retail traders are disposed to hesitate. It ought to become the test question of a pharmacist's loyalty to his calling, whether he is or is not in favour of the abolition of Company Pharmacy. If he be disposed to hesitate or inclined to do nothing because of the magnitude of the task, he is not one of our friends. In this, as in higher questions of human affairs, "he that is not for us is against us." Some of you will be disposed to think I am now fighting a shadow. I am not. There is more lukewarmness than you think in the higher ranks of pharmacy. Only last year Mr. Leo Atkinson boldly said at the annual meeting of the Society that he thought we ought to give up the agitation against company pharmacy. If you happen to know any wholesale dealers who have accounts with these firms ask them what they think about it. You will soon see the necessity of bringing the trade into line on this matter. All are concerned. In the story of Tarquin it was the tallest poppies he cut down first. In this case they will live the longest, but our Tarquin will cut them down if he be not cut off himself.

Mr. Carteighne only spoke at Edinburgh the soberest truth when he said that there was no hope of successfully dealing with the companies unless the trade was united. To get a united trade you will have to give some people an uncomfortable hour or two, and not leave them until they find "salvation."

When we have got all pharmacists who are in the business, wholesale or retail, into line on this question, we shall be better able to deal with those men who, by serving the companies, enable them to carry on business. I am not just now going to throw stones at these men. The companies they serve have a legal position, and so I cannot regard them as quite outside the pale of reason. Besides, they have at least one good excuse. I set aside all the talk about their better conditions of employment, etc., etc. In some cases it is true, in many it is untrue. These companies would not change assistants so often if their shops were quite the Edens they are represented to be. No, these men have a better reason—it is that they are only doing with their labour what other and higher placed pharmacists do with their goods—selling to the limited companies. It may be quite right for A.B. to sell his specialties or drugs to company pharmacists—and quite wrong for C.D. to sell his services to the same firm.

I, however, cannot see where the difference comes in. The casuistry which makes it right to do the one thing and wrong to do the other is beyond a plain Lancashire lad like myself. I can only say "such knowledge is too wonderful for me, I cannot attain unto it." I am willing to admit there may be a difference in degree of offence, but none in kind. But when we have all done our heart-searching, and got rid of all interested views of this thing—when we have got something like solidity of opinion in the trade, and are prepared to treat both classes of offenders as they may deserve—any appeal we may make to those company servants will stand any infinitely better chance of a favourable response than at present.

Then we need to do another thing. We need to imitate the Parliamentarians of Cromwell's day by passing a self-denying ordinance. We need to get rid of the "Widows' Clause," and consent to a limitation of the number of pharmacists a single trader or firm may conduct. To go to Parliament with the maintenance of these two things inscribed on our banner is to invite defeat. Our strongest point is that, although simply traders as regards the bulk of our business, yet, as the State-licensed retailers of poisons, we have a personal qualification which gives us a professional side.

It is this personal licensing and personal qualification on which the Pharmacy Acts insist, and on which we base our claim. But the "Widows' Clause" cuts out our contention and leaves us practically speeches. The multiplicity of branches owned by one man is not perhaps so logically unsound, but it is dangerous to our plea. How can a man owning eight, ten, or twenty branches give that personal attention to his businesses which the Acts suppose he will give and the public have a right to expect. I will leave that, but about the Widows' Clause I have a little more to say. Is the clause one really valuable to pharmacists as a whole? I think not. It is there for every man's use if need be. In the vast majority of cases it is unused. Is it not a fact that in most cases where a deceased chemist has left no son ready to succeed him, that the best thing the widow can do is to sell the business as well and as quickly as possible? Is it not generally done? If I am right in putting the questions that way I should like to ask if it is worth while trying to retain this clause at the expense of perpetuating company pharmacy? I think not.

It should be, and is, possible to devise a plan by which the estate of a chemist dying without a qualified son to succeed him, may be safeguarded from a disastrous forced sale, other than the plan of allowing his widow or executors carry on the business. This being done, cases of hardship would be reduced to a minimum.

Let us look now at the matter from another point. I have heard it said that the public, being interested in getting goods at lowest prices, will not listen to anything like creating a monopoly for pharmacists. Consequently, it is said, we need not hope for legislative redress of our grievances. We are not without answer to these objections.

In the first place, we ask for no monopoly except that of dealing in poisons, and this only because the State forced personal qualification on us. Theoretically we have that monopoly. Practically, owing to the wording of the Act of 1888, we have no exclusive right to sell poisons. We only ask that the public, through the State, should be consistent and treat us justly.

Then you must not forget that even if company pharmacy be made illegal we shall by no means be free from company competition. It would only destroy utterly the man who gets relatives to form a limited company, and then practically is in business
for himself. From the large Civil Service Stores, Household Stores, and firms like Lewis's, it would only take the right to sell and dispense poisons, and preparations containing poisons sold under the Stamp Act. It would not destroy, and, perhaps, ought not to destroy, these firms. They would be left free to compete with us in everything else we sell besides poisons, and they would effectually secure the public from the suggested ravages of the protected pharmacist. From their competition in all but pure pharmacy we have no right to legislative protection, and we shall never get it. To ask it is a childish crying for the moon, unworthy of men engaged in serious occupations.

I feel so strongly on this point, that I cannot understand why certain pharmacists are willing to bring in a Bill containing a clause restricting the sale and dispensing of B.P. preparations to registered men. If the public will not let us put down company pharmacy, they most certainly will never grant us the sole right to make, sell, and dispense B.P. preparations. I pointed this out when Mr. Carteigh was here a few years ago, and he has not yet answered the objection, so far as I know.

Again, the public can be shown that their interests will be sufficiently safe, even if there were none but personally qualified men in the drug trade. Competition in our own ranks is keen enough to protect the public against exorbitant prices. Many chemists have gone permanently into the cash trading system, and more will follow. These and the natural growth of competition will keep prices at what, from a public aspect, are reasonable and fair. Whether they will be reasonable and fair from our point of view is another story, as Rudyard Kipling would say. But for that grievance I see no redress, and care little to ask for one.

We want these views embodying a Bill introduced by the Pharmaceutical Society. The President of the Society frequently asks for support and direction from the trade. I think that kind of appeal has been made enough. The Society has done too much waiting for orders to march. It is time they began officially to lead. They waited until they were directed by medical opinion to proceed with the strict enforcement of Clause 17. It will be more statesman-like and dignified if the Society as represented by its official heads were to initiate a forward movement in the shape of promoting a thorough Pharmacy Act Amendment Bill. Until some big imperial questions are settled, and the House of Commons has become once more a machine for transacting public business, the chances of the Bill will be very few indeed. But whilst we are settling the big public questions, the time can be usefully employed in defining our wants, in closing up our own ranks, and in educating those to whom we shall ultimately have to appeal. Then when our opportunity comes we shall be able to make the best of it.

Finally, we want a greater feeling of comradelship between pharmacists of all ranks. Our Society is really a trades union. We ought all to belong to it. We have common interests to promote, and common foce to meet. We should do both unitely. The man who has the same interests and objects in life as a few thousand other men ought to join himself to them. If he does not, he is not only a source of weakness to them, he is false to his own interests. He deliberately handicaps both them and himself in the race for trade and living. A good trades union looks after the rights of its members. What does that mean but that its members look after their own rights? So with us. We have in the Society a trades union. Let us make it one worth something to us. To do that we must not only belong to it and take an intelligent interest in its proceedings, we must regard all our fellow-pharmacists as men having like interests with ourselves, and work to promote unity of aim. To do this we shall need to get rid of the petty jealousy which mars too many of our efforts. We shall have to learn better how to compete in a friendly way with each other, and at the same time unite for trade purposes, offensive and defensive. We live and work, I think, too much alone. We want to come more together, and in the equality that comes of intercourse we shall lose much of our narrowness and angularity.

With Ruskin, I do not wonder at what men suffer, but I often wonder at what they lose. I do not wonder that we suffer from competition, from the capacity of outside traders, from the heat and pressure of the time and age. Such is the lot of almost all men. But I do wonder that we lose the help, the solidity, the public respect, the sense of comradeship, above all the material success which are the rewards of unity of feeling and action.

In the course of it he interpolated the remark that he had not included photographers among the unqualified persons who should not be allowed to sell poisons, but the remarks he had made about photographers applied to them equally.

The President, opening the discussion, remarked that Mr. Taylor had suggested that more stringent regulations should be enforced for the wholesale sale of poisons. Mr. Taylor was of opinion that poisons of should only be sold in a wholesale way to registered persons. That he (the chairman) believed could never be done. The moment an attempt was made to put stringent restrictions on the wholesale sale of poisons the cry would be raised, "You are interfering with the arts!" Still, there was room for considerable improvement of the regulations, which might well be made more strict than they were. Mr. Taylor had made reference to dividend hunters, but these were not the only men they had to contend against. They had to compete with men who were selling the goods of chemists and druggists at nearly cost price in order to decry the public into their establishments, in the hope of inducing the public to buy goods upon which there was a much larger profit. He (the President) quite agreed with Mr. Taylor on the subject of the widows' Clause. He was particularly convinced of the desirability of widows disposing of the businesses as quickly as possible. In the present state of trade it was not possible for a woman to engage a qualified assistant and carry on the business successfully. That could not be done in nine cases out of ten, and he thought the "Widows' Clause" would not be such a great sacrifice as was supposed, if the trade could make up its mind to
part with it. In reference to some recent prosecution
for particula
tions, Mr. Taylor must not forget that those prosecu-
tions were only a fraction of a very large section of
chemists and druggists in the country. Concluding,
the President moved a vote of thanks to Mr. Taylor
for his valuable and interesting paper.
The motion was seconded by Mr. Kirkby, and
supported by acclamation.
Mr. Taylor was received with applause,
first referred to the glaring inequalities of which
Mr. Taylor had spoken, among those who were
connected with the Society. He reminded the
meeting that in 1883, when there was to a
certain extent a general federation of the whole
trade under the Act, then passed, the Society
consisted of only about three per cent.
The general federation of the trade, and the registering
of chemists and druggists, were steps taken, not on
the principle upon which the Pharmaceutical Society
had been established, but simply and solely as a
State matter for the protection of the public. The
Act was not designed to protect the public, but rather
as a means of securing a-class system for the
industry, the object of which was to prevent
the low-priced goods from being sold to
the public. The general federation of the trade
would be a chemical trade, and a trade directly,
in any way whatever, although it was proposed at the time that chemists
and druggists, who then became recognised as
registered persons should be admitted to the Society—
the idea was that they were only a vanishing quantity
and that the course of time and trade would cease to exist altogether, and every man in
the trade would be a chemical trade. It was
under those conditions that the number of chemists and
and druggist members of the Council was confined to
one-third. However, the idea of the founders of the
Pharmaceutical Society had not been obeyed in effect.
The men who had qualified since 1888 on the
Minor basis were very numerous. They numbered
something like 3,000, against upwards of 2,000 phar-
aceutical chemists. Under those altered conditions
it was very reasonable that there should be an
alteration in the constitution of the Society, and
that view had been accepted and recognised by the
Council of the Society for years past. It had been
included in the several Bills which had been intro-
duced into Parliament. Parliamentary interference
was necessary in this matter. All those Bills had failed to
pass, and it rested with the chemists and druggists to
enforce their principles. The Council of the Society was perfectly willing to
adopt the change. The "Widows' Clause" Mr. Taylor
had spoken of as an insuperable obstacle to dealing
with company trading. He (Dr. Paul) did not think
that was the case. There were very few cases in
which it was not possible to get rid of the widows.
The business of the whole sale of poisons (Dr.
Paul continued) was fully provided for in the Act.
The Act said that wholesale trading in poisons should
be exempt from the provisions of the Act, so far as
ordinary wholesale trading was concerned, and the
seventeenth section made that position still more
clear by stating the ordinary course of wholesale
dealing to retail dealers. Registered men alone were
able to retail poisons, and the Act contained a pro-
vision that the wholesaler supply should be secured by qualified retailers. That provision,
ever, had never been acted upon. One point which was
especially deserving of the attention of chemists and
and druggists at the present time was the want of more
regard for the educational basis of their qualifi-
cation, as it was by only safeguarding and improving the present position that chemists might hope to
effect any good for themselves.
The work of trade protection would never
be done by the Council of the Pharmaceutical Society.
It was a work which must be done by the
chemists themselves, by active association.
It was not possible to see company trading supported
by qualified men, especially as they knew that
company trading could not exist for a day if it were not
for the support of qualified men. Chemists had in their
own hands the means of putting a stop altogether to
company trading so far as there was any legal protec-
tion accorded by the Act. In his opinion legislative
protection was required with regard to the general
exercise of pharmacy, dispensing, and the preparation
of medicines, quite as much for the sale of poisons.
The conditions of competent qualification in his opinion
were far too little to ensure the protection of trade inter-
estes. The interests of the trade were very materially
larger, by "value" of other people who had failed to pass
their examinations. The engagement of apprentices who had
not passed the Preliminary examination was another cus-
tom which was materially detrimental to qualified men.
The future prospects of the trade depended much
more largely upon organisation among the members of the trade, to make sure that the examination questions,
their own and the examinations of others, were passed.
There was no knowing how a Bill would be mauled in
Parliament, no matter how well drafted and how
reasonable it might be.
Mr. Pendlebury complained that among the examin-
ning body were men who did not know properly the
subject in which they examined.
Mr. J. R. Young, of Warrington, pointed out that,
though chemists and druggists were entitled to one-
third of the seats on the Council, they had never seen
fit to increase their representation beyond three. He
argued that if the Council sought to abolish the
"Widows' Clause" 50 per cent. of the trade would
be against them.
Mr. H. Kemp agreed with Mr. Taylor that there ought
to be an Act preventing wholesale dealers in poison from
selling to herbalists. There would not be half the
illegitimate trading that there was if the whole dealers
were restricted to those for legitimate retail traders.
He agreed with Dr. Paul that the "Widows' Clause"
ought to be restricted, and not abolished, and contended
that the best interests of the trade would be served by
making the examinations of the students stiffer.
Mr. Taylor having briefly replied, the discussion
ended.

SHEFFIELD PHARMACEUTICAL AND
CHEMICAL SOCIETY.

A meeting of the Sheffield Pharmaceutical Society
was held in the Society's Rooms, on Wednesday night,
to discuss some aspects of pharmaceutical politics.
Mr. J. E. Bailey presided and there was a fair attend-
ance of members and associates.
The Chairman introduced the subject of the debate
by reading some long extracts from a recent speech by
Mr. Carteige at a meeting of the Glasgow and West
of Scotland Pharmaceutical Association, in which that
gentleman gave a sketch of the history of pharmacy
legislation, with special reference to the operation of
the "Widows' Clause," and the tendency of it to foster
company trading. Mr. Carteige declared that the
pharmacy law was defective in many ways, and that
it would be useless to attempt any reform without the
full support of the trade. The Chairman added some
strong expressions of approval of Mr. Carteige's views,
and that the great trouble seemed to be the
"Widows' Clause."

Mr. W. Ward said he wished that the subject for
discussion had been pharmaceutical econo-
mias, because his experience had led him to conclude that a discussion of pharmaceutical politics was of very little use. They were bound to admit the fact that one of the underlying mischiefs of the present conditions had been simply appalling. He could come to no other conclusion than that one great reason for the position into which the trade of the pharmacist seemed to have fallen, was their want of a united and a common family among the chemists and druggists of the United Kingdom. Experience had taught them also that they could not look to the State for help. The State had done as much as was possible in the general condition of free trade principles, and it seemed to him that pharmacists would have to fall back on their own resources, and exercise their own judgment in determining how they might make the best of the unfortunate circumstances in which they were placed. Mr. Cartelhe had said a good deal about the effect of the "Widows' Clause," but what was now being said was simply what he himself foretold several years ago when he delivered a speech at Leeds on pharmaceutical politics. He then expressed his regret that such a clause should be introduced into the Pharmacy Bill, but no one took his view of the matter. Events had proved, however, that the inclusion was unfortunate, and was plain to them all that it would be a difficult thing to get the clause engrafted. He believed it would have been to the advantage of the widows themselves if the clause had never been inserted, and he would now strongly go in for the expunging of it. In some further observations he dwelt upon the absolute necessity for greater unity in the profession.

Mr. H. J. Cobb said for his part he thought it was useless to try to eliminate the "Widows' Clause" or to stop company trading, for the judges had laid it down that it did not matter who found the capital as long as a proper man was employed to conduct the business. Though the abolition of the "Widows' Clause" if it could be secured would not do away with company trading, still there was a good deal that the Pharmaceutical Society could do. They might look to the Colonial laws for guidance in many things, especially in the direction of securing the registration of the managers of pharmacy establishments, and of securing that the name of the actual vendor should be placed on the poisons.

Mr. C. G. Morrison agreed with what had been said about the difficulty of amending the pharmacy law in the direction indicated, and said that, as practical business men, they must ask themselves whether such an amendment as the expunging of the "Widows' Clause" would result in the public being better protected. If they went to the House of Commons with a Bill, this would be the first question they would be asked, and on their answer everything would depend. He said it was a shame and a disgrace that a company could assume a title by simple combination which an individual could only take by examination. He believed, however, that the professional professorship of the business was now as much in the hands of pharmacists as ever it was. To maintain this, they must commence with the apprentices. It was high time that the preliminary examination was stiffened, and he thought, too, that they should have a curriculum. The object of all such things did not consist in idea, but was internal education, and they ought to be ashamed of themselves for it. Another thing was the lack of union, which was most deplorable.

Mr. Greaves and Mr. Davy endorsed the observations of Mr. Morrison, and subsequently Mr. G. Squire, honorary secretary, Mr. Halting, and others spoke. The Chairman summed up the discussion, but no resolution was put.

Afterwards the subject of establishing a price list was discussed.

SUNDERLAND CHEMISTS' ASSOCIATION.

The annual dinner of the Association was held at the Grand Hotel on Wednesday, the 12th inst. The President, Councillor Harrison, J.P., president, and there were also present the following officers of the Association:—Mr. R. H. Bell, Secretary, Mr. Leadbitter, Treasurer, Messrs. White, Ranken, Walton, Asken, and Todd, members of council, and a large number of members and friends. After the loyal toasts had been duly honoured, Mr. C. Bell proposed "The Pharmaceutical Society," which was suitably responded to by Mr. C. Ranken, the Local Secretary of the Society.

The President, in responding to the toast of his health, congratulated the members on the increased and vital influence thus shown by the Association, and expressed his earnest desire to see its sphere of usefulness largely increased by the extension of opportunities for the consideration and discussion of matters connected with the craft. He referred also to the work of the Pharmaceutical Society, and pointed out how its influence for good could be greatly increased if only the majority of those engaged in the practice of pharmacy would join its ranks. Other toasts followed, and an enjoyable evening was spent.

Parliamentary and Law Proceedings.

PROCEEDINGS UNDER THE PHARMACY ACTS.

ACTION AGAINST AN UNREGISTERED PERSON.

At the Bow County Court on Friday, December 7, before his Honour Judge French, Q.C., the Pharmaceutical Society sued F. F. Ward, of 1, Tredegar Road, Bow, for two penalties of £5 each, one for keeping open shop for the retailing of poisons, and the other for assuming or exhibiting the title of Chemist contrary to the Pharmacy Act of 1868.

Mr. T. R. Grey (instructed by Messrs. Flax, Thompson, and Flax) appeared as counsel for the Pharmaceutical Society. The defendant appeared in person.

The defendant at once admitted his liability, and his Honour gave judgment for the plaintiffs, with costs.

SALE OF POISONS BY AN UNREGISTERED PERSON.

At the Mansfield County Court, on Monday, before Judge Masterman, D.C.L., Edwin Buckland, shopkeeper, was sued at the instance of the Pharmaceutical Society, who sought to recover a penalty of £5 for an infringement of the Pharmacy Act of 1868.

Mr. T. R. Grey (London), instructed by the solicitors to the Society, appeared in support of the summons, and Mr. E. H. Fraser (Nottingham), defended.

Mr. Grey, in opening the case, said that the defendant carried on business at Sutton-in-Ashfield, near Mansfield, under the style of 'Buckland's Drug Stores,' and the prosecution was instituted under 31 and 32 Vict., cap. 101, which was an Act to regulate the sale of poisons. On October 17 last, a witness, who would be called before the court, went into the defendant's shop and asked for some soap liniment and laudanum. The defendant replied that he was out of one of the ingredients, and he sent a boy for it. The boy returned and handed the bottle to the defendant, and they were together. On the same day the witness asked for another compound, containing oil of peppermint, paregoric, oil of aniseed and laudanum. The defendant, observing that he was just out of laudanum, again sent the boy out, and when he returned the defendant mixed the ingredients from other bottles in the shop. Both bottles were afterwards handed over by the witness, and on their con-
tents being analysed they were found to contain laudanum. Mr. (Gray) did not know what the defence would be, but it was no defence to say that he sent out for the poison and got it from a chemist, as the person who sold the substance was liable. The defendant did not only send the poison, but his shop was kept open for compounding it within the meaning of the Act.

Arthur Foulds, an inquiry agent, of Salford, stated that he was instructed by the Pharmaceutical Society to make certain purchases at 14, King Street, Salford-in-Ashfield, and on going there he found a small sign, upon which were the words "Buckland's Drug Stores." Witness asked to be supplied with two pennyworth of laudanum and two pennyworth of soap liniment mixed. Defendants said that he was out of one of them, but he did not say which, and then sent his boy for it. Witness afterwards asked for a cough mixture, consisting of one pennyworth each of oil of peppermint, oil of aniseed, paregoric and laudanum, and the defendant said, "I am just out of some of them, but if you will wait, I will send for them." Witness afterwards received the mixture, and, sealing both bottles up, handed them to Mr. Stroud, managing clerk to the plaintiff's solicitors.

Cross-examined by Mr. Fraser, witness stated that he was not aware that there were two persons of the name of Buckland carrying on business. He was not informed that the defendant did not sell laudanum. He never saw any ingredient put into the first bottle before it was taken from the shop, nor did he see that the label on the bottle was that of G. W. Briggs, Suttonin-Ashfield. When defendant's boy returned with the second bottle there was a small quantity of liquid at the bottom. The boy handed it to defendant, who poured in other liquids from large bottles in the shop.

Mr. T. W. Stroud then deposited to having received the bottles from the last witness, and that they were both sealed.

Mr. E. J. Eastes, analyst, said that he received the bottles from Mr. Stroud on November 3, and analysed their contents, finding that the first preparation contained opium. The amount of morphine present was 2.2 grains. The second purchase also contained opium, but to a smaller extent.

For the defence, Mr. Fraser contended that there was no evidence to prove that the contents of the bottles could not have been changed in the meantime. The ingredients taken from the shop were two sealed bottles, and two other bottles were afterwards delivered to some body. The defendant commenced business in the month of August, when he opened the shop for the sale of any drugs except poisons. He had never dispensed a single prescription, or sold a single poison. When a person came in for an ordinary drug he sold it, but if a poisonous drug was wanted he sent for it to Mr. Briggs, a qualified chemist. The defendant always required the money for it before it was sent for. The whole of the cough mixture was compounded in the shop of Mr. Briggs, and all the profit was taken by him. As far as he could judge, there seemed to be a complete absence of the caution which was generally exercised in such cases. When any article was purchased for the purpose of analysis, it was necessary that the salesman should be informed of it.

Edwin Buckland, the defendant was then called, and said that he never had any laudanum except when he asked the chemist to go for it. The compounds in the bottles produced were not compounded in his shop, but by Mr. G. W. Briggs. With regard to the second bottle, that bore the label of Mr. Briggs, and witness got no profit on it. Cross-examined, defendant admitted that he might have said that he was out of one of the drugs. He was prepared to swear that Foulds gave the boy the money for the first purchase. Witness never touched the bottle when the boy brought it back. Foulds taking it off the counter.

The defendant's boy having corroborated this statement, George William Briggs, pharmaceutical chemist, Sutton-in-Ashfield, stated that he occasionally supplied goods to Mr. Buckland, but rarely in poisons. Witness, however, supplied the compound in question, and placed a label on it.

Cross-examined: On the second bottle witness put his own label and also a poison label, but these must have been removed.

His Honor gave an opinion of judgment, said that he was satisfied that the prosecution had not thoroughly made out their case, and he would therefore give the defendant the benefit of the doubt. As to the question of costs, he thought the Pharmaceutical Society were quite justified in bringing the case forward, and he therefore could not allow the defendant's costs.

Answers to Correspondents, etc.

R. H.—The addition can be made, but it will be necessary to send the instrument to an optician for the purpose. Baker, of 243, High Holborn, London, could effect the alteration for you.

Correction.—On page 484, column 1, line 31, for "kleinost®" read "kleinost".

Diary of the Week.

MONDAY, DECEMBER 17.

Imperial Institute.

House Dinner, at 6.45 p.m.

"The Papuan at Home; or a Visit to British New Guinea," by Ballyse Baildon, at 8.30 p.m.

Society of Arts, at 8 p.m.

"Modern Developments in Explosives" (Lecture 1V.), by Professor Vivian B. Lewes.

TUESDAY, DECEMBER 18.

Central London Throat and Ear Hospital, at 4.30 p.m.

"Doubt in Diagnosis as Determined by Clinical Observation," by Lennox Browne.

WEDNESDAY, DECEMBER 19.

Imperial Institute.

Concert Dinner, at 6.30 p.m.

Ladies' Concert, at 8.30 p.m.

Society of Arts, at 8 p.m.

Royal Pharmaceutical Society, at 8 p.m.

Ordinary Meeting of the Society.

Western Chemists' Association (of London) at 9 p.m.

Introductory Address by the President, at 1, Crane Road, W.

THURSDAY, DECEMBER 20.

Imperial Institute, at 4.30 p.m.

Linen Society of London, at 8 p.m.

Chemical Society, at 8 p.m.

"An Improved Form of Barometer," by Dr. N. Collie.

"The Chemical Constituents of Piper Ovatum," by Professor Dunstan, and H. Garnett.

"Note on the Active Constituent by the Pelletrary of Medicine," by Professor Dunstan, and H. Garnett.

"The Preparation of Adipic Acid," by Dr. W. B. Ince.

FRIDAY, DECEMBER 21.

Quedelt Microscopical Club, at 8 p.m.

Ordinary Meeting.

COMMUNICATIONS, LETTERS, etc., received from Messrs. Addison, Bannerman, Bell, Blackburn, Brown, Browne, Clarke, Cocks, Cross, Crowhurst, Dewar, Dunn, Harrison, Henry, Hill, Jones, Ken, Kershaw, Lewis, Martin, Martindale, Moffat, Phillips, Powell, Prince, Taylor, Thirlby, Tocher, Tarver, West, Young.
THE DISCOVERY OF OXYGEN.

(Continued from page 438.)

JOSEPH PRIESTLEY.

Joseph Priestley was born on March 13, 1733, at Fieldhead, near Birstal, in Yorkshire. He was the son of a woollen-cloth dresser, possessing only moderate means, and was educated as a Nonconformist minister. After taking charge of congregations at Needham Market, in Suffolk, and, later, at Nantwich, he was appointed classical tutor in a Nonconformist academy at Warrington. Subsequently he took charge of Mill Hill Chapel, Leeds, and adopted Unitarian ideas, and, finally, he removed to Birmingham, where his chapel and house were burnt down in 1791 by a mob which associated him in error with a dinner held to commemorate the capture of the Bastille by the French revolutionists. All his manuscripts, apparatus, and other valued material possessions were destroyed, and the labours of years wasted. Leaving Bir-

mingham, he spent three years in Hackney, and in 1794 proceeded to Northumberland, Pennsylvania, where he died on February 6, 1804.

Whilst a student, Priestley acquired three modern languages, in addition to Latin, Greek, Hebrew, Chaldean, Syriac, and some Arabic. Mathematics, natural philosophy, logic, and metaphysics, also occupied much of his attention, and after settling at Nantwich he devoted much time to the study of chemistry and electricity. He received the complimentary degree of L.L.D. from Edinburgh whilst at Warrington, and in 1766 his work in electricity procured his election to the Royal Society. The following year he published his ‘History of Vol. LV. (Third Series, Vol. XXV.), No. 1278.

Electricity’; in 1774 his ‘Experiments and Observations on Different Kinds of Air, etc.’ began to appear; and in 1800 he published a treatise entitled ‘The Doctrine of Phlogiston Established, and that of the Composition of Water Refuted.’

According to Roscoe and Schorlemmer, no one obtained more important results or threw more light upon the chemical existence of a number of different gases than Joseph Priestley. In 1772, he proved that the burning of combustible bodies and the respiration of animals both deteriorate air and diminish its volume. Attributing these effects to the addition of phlogiston to the air, he gave the name "phlogisticated air" to the gas (nitrogen) left after treatment of the impure air with milk of lime, which removed the carbon dioxide (fixed air).

The air deteriorated by combustion or respiration he afterwards found could be rendered again capable of supporting combustion by the action of living plants, which he assumed to be capable of removing the phlogiston.

On August 1, 1774, he first obtained oxygen gas (dephlogisticated air) from red precipitate, and his was the first printed account of its discovery. He was also the first to prepare nitric oxide (nitrous air), nitrous oxide (diphlogisticated nitrous air), and carbon monoxide; and to collect over mercury ammonia gas (alkaline air), hydrochloric acid gas (marine acid air), sulphurous acid gas (vitrilic acid air), and silicon tetrafluoride (fluor acid air). He devised the "pneumatic trough," as we now know it, in the course of his experiments. In addition, he observed that an increase of volume occurred and a combustible gas was formed on passing electric sparks through ammonia gas; that nitrogen gas (phlogisticated air) was evolved on heating ammonia with coke of lead; and that water aerated with carbon dioxide could hardly be distinguished from salt water. In commenting upon the fact that "the pressure of the atmosphere assists very considerably in keeping fixed air confined in water," he virtually suggested the idea of the manufacture of so-called "soda-water."

PRIESTLEY’S WORK ON OXYGEN.

In the third section of his "Experiments and Observations on Different Kinds of Air," Priestley remarks that there were few maxims in philosophy that, at the time he commenced his investigations on the subject, had laid firmer hold upon the mind than that atmospheric air freed from impurities was a simple elementary substance, indestructible and unalterable. He proceeds to say that he was soon convinced of the error of this opinion, "for that the phlogiston with which it (the air) becomes loaded from bodies burning in it, and animals breathing it, and various other chemical processes, so far alters and depletes it as to render it altogether unfit for inflammation (combustion), respiration, and other purposes to which it is subservient; and I had discovered that agitation in water, the process of vegetation, and probably other natural processes, by taking out the superfuous phlogiston, restores it to its original purity."

He had previously been led to conclude that common air consisted of marine (hydrochloric) 1

1 The portion of this work bearing on the discovery of oxygen is reprinted in a convenient form by the Alemia Club (Edinburgh: W. F. Clay).
acid and phlogiston, his method of reasoning being as follows:—The union of marine acid vapour and phlogiston, by the action of the acid on certain metals or inflammable substances, produces inflammable air (hydrogen); and “inflammable air, by agitation in water, ceases to be inflammable, and becomes respirable, like ordinary air.” Though he could never make the residue quite so good as common air, he thought it very probable that vegetation, in more favourable circumstances than any in which he could apply it, quently became sufficiently purified by vegetation to be fit for respiration. On this hypothesis it was apparently assumed that plants previously flourished in the absence of an atmosphere, or that they were developed simultaneously with, but yet independently of, it.

**Experiments and Results.**

The results of a series of observations now undertaken by Priestley, however, compelled him to give up this hypothesis, and led him unexpectedly to the solution of the great problem which he had “had in view ever since his discovery that the atmospheric air is alterable, and therefore that it is not an elementary substance, but a composition,” the problem being “what this composition is, or what is the thing that we breathe!” In his experiments he placed various substances in vessels (a, fig. 1), which were then filled with quicksilver and inverted in a basin containing the same metal. Ignition of the enclosed substance was then performed or attempted by means of a large burning-glass or mirror, this operation being performed in much the same manner as represented in fig. 2. Any gas or vapour given off, displaced part of the mercury in the vessel a. Under this treatment *mercurius calcinatus per se* (mercuric oxide prepared by heating mercury in the presence of air) yielded “a kind of air” very readily. A candle burned in this air with a remarkably vigorous flame, “very much like that enlarged flame with which a candle burned in nitrous air (nitric oxide) expired before the iron and sulphur.” But as Priestley had got nothing like this remarkable appearance from any other kind of air besides this particular modification of nitrous air, and knew no nitric acid was used in the preparation of *mercurius calcinatus*, he was utterly at a loss how to account for the phenomenon. In this case, also, though he did not give sufficient attention to the circumstance at the time, the flame of the candle, besides being larger, burned with greater brilliancy and heat in the new kind of air than in the modified nitrous air, whilst “a piece of red-hot wood sparkled in it, exactly like paper dipped in a solution of nitre, and it consumed very fast.”

---

3 The most accurate method of procuring air from several substances by means of heat is to put them, if they will bear it, into phials, such as a, a, a, full of quicksilver, with their mouths immersed in the same, and then throwing the focus of a burning-mirror upon them. (Priestley).

4 Nitrous gas (nitric oxide) being exposed to a large surface of iron during two months, was rendered capable of maintaining flame, and even enlarging the flame, although it continued highly noxious. The same effects were produced by exposing nitrous gas to liver of sulphur (in a mixture of iron filings and to a mask of iron filings and sulphur). (Appendix to Macquer’s Dictionary of Chemistry.) The explanation of the above is that, by reduction of the nitric oxide, which is normally a non-supporter of combustion, nitrous oxide (dephlogisticated nitrous air) was formed. The latter gas, as is well known, closely resembles oxygen in many of its properties, and especially as a supporter of combustion. Priestley’s test as to whether a gas was respirable or not was based on this. He observed by himself, that ruddy flames of nitric peroxide are formed when nitric oxide is mixed with air, which, naturally, constituted his standard of respirability and purity amongst gases. This phenomenon also occurs, and is immediately, in the case of pure oxygen, but in the instance quoted by Macquer the admission of fresh nitric oxide would, of course, be followed by no such effect, as the absence of red flames was mistakenly assumed to indicate unfitness of the nitrous oxide to be respired.
The fact that red precipitate prepared from a solution of mercury in spirit of nitre (nitric acid) yielded a similar air to the mercurius calcinitus led Priestley, bearing in mind his previous experiments with nitric oxide, to think that this evolution of gas depended upon something proceeding from the nitric acid. Further, he considered that since the mercurius calcinitus is formed by the action of heat in the presence of air, it had, whilst in a heated condition, absorbed some essential constituent of nitre from the atmosphere. In arriving at this conclusion, Priestley unconsciously fell back upon the suggestion published by Mayow long previously. This, however, appearing to him much more extraordinary than it ought to have done, he entertained some suspicion that the mercurius calcinitus, on which he had made his experiments, “being bought at a common apothecary’s, might, in fact, be nothing more than red precipitate; though, had I been anything of a practical chemist, I could not have entertained any such suspicion.” Ultimately, this thoroughly justifiable suspicion was dissipated and expelled from the experimenter’s mind after the examination of a specimen supplied by a friend who warranted it genuine. This being treated in water was deprived of its power of supporting combustion, ten times as much agitation failed to produce any sensible change in the new gas. The latter also mixed with common air without the mixture decreasing in bulk as was the case when nitric oxide was added. Again, when one measure of nitric oxide was mixed with two of the new gas, it was found that the total volume of gas diminished, and the mixture remained a red colour, just as had been observed was the case with a similar mixture of nitric oxide and common air. Priestley concluded, accordingly, that the air from mercurius calcinitus was fit for respiration and had all the other properties of common air, but yet remained of opinion that the explanation of the matter was that the compound had extracted spirit of nitre (nitric acid) from the atmosphere.

Confirmatory Experiments.

Fortunately, a lighted candle was by chance introduced into the mixture of the new gas with nitric oxide and found to burn steadily, whereas it had been previously observed that in a similar mixture made with common air the flame was extinguished. Further, a mouse remained lively for twice as long in a vessel filled with the new air as it would in common air, and, though apparently dead when removed, subsequently revived, whilst the usual atmosphere of the vessel in which the experiment had been performed proved to be purer than common air, combining with a much larger proportion of nitric oxide than the latter would, and even then supporting respiration in the case of another mouse. Eventually, then, the belief was forced upon Priestley that the new air must be better than the ordinary kind. “Being now fully satisfied with respect to the nature of this new species of air, viz., that, being capable of taking more phlogiston from nitrous air, it therefore originally contains less of this principle, my next inquiry was, by what means it comes to be so pure, or, philosophically speaking, to be so much dephtlogisticated; and since the red lead yields the same kind of air with mercurius calcinitus, though mixed with fixed air (carbon dioxide), and is a much cheaper material, I proceeded to examine all the preparations of lead, made by heat in the open air, to see what kind of

---

2 Nitrous oxide is soluble in three-fourths its volume of water. In this experiment, therefore, it would be practically all removed in the process of washing. Oxygen, on the other hand, is but slightly soluble in water.

3 It was discovered also that the new air exploded much more violently with inflammable air (hydrogen) than did common air, the best result being attained when the hydrogen constituted two-thirds of the mixture. Priestley estimated that his factitious air, the density of which, as compared with ordinary air, he gave as 132 to 153, was capable of producing five or six times the effect of the latter, the contamination of which he attributed to the phlogiston contained in the vapours mixed with it.

4 Probably due to the presence of lead carbonate in the great oil, from which the air was formerly prepared by the application of gentle heat. As an intermediate stage maseccot, or yellow lead, was formed. The physical changes involved in the chemical decomposition of metallic oxides and other compounds under the influence of heat, were not now observed for the first time, but had in most cases been familiar to experimenters from remote antiquity. The only novelty consisted in the recognition of the fact that previously unknown gaseous bodies were evolved, which possessed distinct properties. Bayen had previously noted that a gas was given off from red oxide of mercury when heated, but did not investigate the matter further, though he subsequently claimed the discovery of oxygen when the facts had been established by Priestley.

---

Fig. 2.—Apparatus used by Mayow in his experiments in pneumatic chemistry. Combustion of the enclosed substance is being effected by means of a burning-glass. The bent tube served to introduce air or various gases into the vessel, and the lighted candle as a test of the power of supporting combustion possessed by the gas evolved from the ignited substance.

As yet, Priestley—taking it for granted that what he was examining was identical with nitrous oxide—had no idea that the new gas was wholesome. But a larger supply of it was now prepared and examined as to its properties. Its extraordinary power of supporting combustion convinced him that there was a very material difference between it and the modified or phlogisticated nitrous air. Whilst the latter, after a few moments agitation in
air they would yield, beginning with the grey calx (impure lead oxide), and ending with litharge."

As a result of these experiments, the "dephlogisti-
cated" air (oxygen) was obtained from massicot, lead ore, grey calx of lead, and litharge. The next step was to moisten red lead with vitriolic (sulphuric), marine (hydrochloric), and nitrous (nitric) acids, respectively, and dry and powder the resulting mixtures, which were then heated separately in a gun-barrel. The portions that had been treated with the first two acids became white and gave off no gas on heating, as was to be expected seeing that all the oxygen would have been previously driven off in the process of drying. The third portion, which would contain lead nitrate and, probably, undecomposed carbonate, became deep brown, and yielded a mixture of fixed air and dephlogisticated air (carbon dioxide and oxygen).

The red lead and other substances, which had yielded all the oxygen that could be extracted from them by this process, were further found to yield as much as at first after being moistened with fresh nitric acid and treated as before. Priestley was now convinced, therefore, that, agreeing to his original conjecture, it was the nitric acid which the red lead, etc., had acquired from the air, which had enabled them to yield the dephlogisticated air. "Finding also... that the same kind of air is produced by moistening with the spirit of nitre any kind of earth that is free from phlogiston, and treating it as I had done the red lead in the last-mentioned experiment, there remained no doubt in my mind but that atmospheric air, or the thing we breathe, consists of the nitrous acid and earth," with so much phlogiston as is necessary to its elasticity; and likewise so much more as is required to bring it from its state of perfect purity to the mean condition in which we find it."

PRIESTLEY'S SUGGESTIONS AND CONCLUSIONS.

In the course of numerous experiments, Priestley subsequently obtained the dephlogisticated air from nitre, alum, and a large number of other substances, such as flowers of zinc, chalk, clay, gypsum, magnesia alba, wood ashes, flints, Muscovy tallow, and even usels; and being to heat the substance alone, or after moistening with nitric acid and drying, in a gun-barrel, or a phial into the neck of which was fitted a bent glass tube (c, d, fig. 1). The gas was collected over water, and there was found to be a great variety in the purity of the dephlogisticated air procured from the same substances. But this will not be wondered at, if it be considered that a small quantity of phlogistic matter, accidentally mixing with the ingredients for the composition of this air, depraves it."

"In making the experiment in question, it was not very necessary that air be not very rapid, there will be time for the phlogiston to be disengaged from the iron itself, and to mix with the air."

Sometimes, therefore, the gas given off was fairly pure, but occasionally it was "so charged with phlogiston as to be perfectly noxious," or, again, it consisted to a greater or less extent of nitric oxide, whilst the red lead employed was perhaps reduced to the metallic state, and the residue difficult to remove from the gun-barrel.

In discussing the latter difficulty the necessity of keeping the apparatus used in proper order is enlarged upon by the experimenter, who quaintly summarises the matter in the following terms: "If, therefore, any person shall propose to make dephlogisticated air in large quantities, he should have an apparatus appropriated to that purpose; and the greatest care should be taken to keep the instruments as clear as possible from all phlogistic matter, which is the very bane of purity with respect to air, they being exactly plus and minus to each other."

Priestley suggested that his hypothesis, "that atmospheric air consists of the nitrous acid and earth," accorded well with the facts relating to the production of nitre, which he attributed to a decomposition of the air, and the combination of the resulting nitric acid by "such kinds of earth" as were supposed to have an affinity for it. He also accounted for the disappearance of the nitric acid, on the denotation of nitre, by assuming that it combined with some "earthly or inflammable matter, with which it forms some of the many species of air, into the composition of which this wonderful acid enters." Further, he inferred that the introduction of a quantity of very pure dephlogisticated air into a room "in which much company should be confined" would agreeably qualize the noxious air of the room, "so that from being offensive and unwholesome, it would almost instantly become sweet and wholesome. This air might be brought into the room in casks, or a laboratory might be constructed for generating the air and throwing it into the room as fast as it should be produced."

Other ideas that suggested themselves to him were: to fill the interstices of gunpowder with dephlogisticated air rather than common air, so as to increase the force of the explosion; to increase the force of blows by blowing them with the pure air; and to aid the lungs in throwing off "the phlogistic putrid effluvium" in certain morbid cases. In this connection it is sagely remarked "that though pure dephlogisticated air might be very useful as a medicine, it might not be so proper for us in the usual healthy state of the body; for, as a candle burns out much faster in dephlogisticated than in common air, so we might, as a secondary cause, be let out too fast, and the animal powers too soon exhausted in this pure kind of air."

Ultimately, Priestley concluded that common air is composed of one volume of "dephlogisticated air" to four volumes of "phlogisticated air." These proportions accord well with those in which oxygen and nitrogen are now known to exist in the atmosphere. At the same time he did not recognize..."
n the latter constituent a distinct substance, but regarded it simply as a combination of pure air (oxygen) with phlogiston.

VALUE OF PRIESTLEY'S WORK.

It will be seen, then, that in spite of his want of system, and perhaps even on account of it, Priestley not only discovered oxygen but anticipated much of what we now know regarding it, though, as already mentioned, he failed to fully comprehend the bearing and importance of the phenomena he observed during the course of his investigations. He retained until the end of his life a firm belief in the truth of the phlogiston theory, thus affording an instance of the truth of his own statement that "We may take a maxim so strongly for granted, that the plainest evidence of sense will not entirely change, and often hardly modify, our persuasions; and the more ingenious a man is the more effectually he is entangled in his errors, his ingenuity only helping him to deceive himself by evading the force of truth."

Nevertheless, he was mainly though unconsciously instrumental in destroying this theory by his life-work, and particularly by his discoveries with "phlogisticated air," which was the chief of the remarkable results he attained in his prolonged work on gases. When confirmed later by the publication of Scheele's work, the matter was left in such a position that it only required the clear perception of a mind like that of Lavoisier, unbiased by the eccentricities of the phlogiston theory, to appreciate the full significance of the facts observed, and arrive at the only logical conclusion by the application of the method of induction.

Priestley was far from systematic in his work, and believed that all discoveries are made by chance; this idea being doubtless fostered by the fact that so little was then accurately known in the department in which he elected to work, whilst so many of Nature's secrets lay as it were close to the surface, ready to disclose themselves at the touch of the most inexperienced hand. The easily-won riches of the mine in which he worked were more likely to demoralise than discipline him as an investigator; and, accordingly, it is not surprising to find that he passed so rapidly from one subject to another that he quite failed even to notice many great truths, the revelation of which was more or less due to his investigations. His work may be described as consisting in great measure in the accumulation of masses of valuable material, which it was left for others to make effective use of. His mind has been described as of rare quickness and perceptive powers, which led him to the rapid discovery of numerous new chemical substances, but it was not of a philosophic or deliberative cast, and though he made and recorded innumerable observations of primary importance in chemistry, their interpretation was left to others.

It has been pointed out\(^8\) that, though Priestley's ingenuity in devising apparatus and skill in carrying out experiments were very remarkable, and placed him amongst the foremost workers in science of his day, many of his experimental results were highly inaccurate, and his conclusions frequently hastily drawn and erroneous. Berthelot, also, has described Priestley as the enemy of all theory and every hypothesis, and as drawing no general conclusion from his "beautiful" discoveries. A passage in the concluding chapter of Priestley's great work, however, goes far to discredit this assertion, for he states that "It is always our endeavour, after making experiments, to generalise the conclusions we draw from them, and by this means to form a theory, or system of principles, to which all the facts may be reduced, and by means of which we may be able to foretell the result of future experiments." As a matter of fact, the careful study of his published results leaves little if any ground for doubting that he adopted the best means available for arriving at the truth, and experimented on the lines indicated in a passage written by a contemporary, that is as pertinent to-day as it was during Priestley's lifetime:—"We cannot too much recommend to chemical operators to be exceedingly upon their guard against imposing and deceitful experiments, which frequently present themselves in practice. A circumstance seemingly unimportant, or not easily perceptible, is frequently sufficient to give the appearance of a great discovery, by means of certain effects, which, nevertheless, are found to proceed from some other cause. Chemical experiments depend on so many accessory things, that all of them can seldom be attended to, particularly when the subject is new; hence, we frequently find that very different results proceed from the same experiment, and at different times. We therefore must not decide after the first success; but the experiment must be repeated several times, and even varied till no doubt can remain."

\(^8\) Preface to Alembic Club Reprint, No. 7.

CINCHONA CULTIVATION IN INDIA.

The cinchona plantations are divided into two categories: (1) Government plantations, and (2) private plantations.

Of Government plantations, the Sikkim plantations in Bengal, under the charge of Dr. King, C.I.E., F.R.S., consist of 2342 acres planted with *Cinchona ledgeriana* (1000 acres), Cinchona "hybrid" (700 acres), and *Cinchona succirubra* (600 acres). The other Government plantations are in the Madras Presidency on the Nilgiris under the charge of Mr. M. A. Lawson, M.A. These consist altogether of 900 acres, but the area under each variety has not been reported.

The private cinchona plantations are situated in the Bengal Presidency at Darjeeling; in the Madras Presidency at Madura, Malabar, the Nilgiris and Coorg; and in the two Native States of Mysore and Travancore. The area under cultivation on private plantations amounts to 6278 acres. Of these 4807 are in the Madras Presidency, and chiefly on the Nilgiris. The out-turn of bark for the year 1892-93 from the Government plantations was 423,873 pounds, and from private plantations 1,458,707 pounds; total, 1,872,580 pounds.

On March 31, 1893, the total number of mature plants on Government and private plantations was estimated at nearly 10,000,000 trees.—*Kew Bulletin.*
TABLET TRITURATES.

Among the modern remedies, or rather means of applying medicines to disease, none seems to have attained such a large share of popularity with the physician as tablet triturates and hypodermics. It is not necessary in a paper of this kind to call attention to any of their advantages as remedial agents, and from the standpoint of the pharmacist alone this would be quite out of place.

Most of the new remedies and special preparations on the market to-day are of such a nature that when their vogue shall have ceased they will go to swell that already large corner in most stores called dead stock. But this is not the case with tablet triturates, for with the outlay of but a small amount, the pharmacist can place himself in a position to supply any demand that may arise for these goods; not only can he supply the demand, but he can do so at quite a large profit to himself over what he would pay the manufacturer, besides doing away with having to keep so many sizes and combinations in tablets always on hand. It is claimed by some that they do not succeed in preparing these goods to equal those of the manufacturers. And while this is no doubt true, yet there is no denying the fact that many pharmacists are turning out tablets of their own manufacture the equal of any made. The wonder is that so small a number are preparing them themselves, when we consider how easily they are made. It is true there are some formulas more difficult to work than others, and that sometimes success does not crown our efforts in a first trial; but by using that discriminating judgment that the pharmacist must possess in order to be successful in his business, there is no reason why he should not easily overcome any difficulty in their manufacture which may arise. Every formula should be carefully noted in a special book, and every detail of manufacture carefully observed.

Many have failed to make as smooth tablets as they would like, simply because the diluent was not in fine enough powder. In making tablets the powder should be fine enough to pass through a 120 sieve. The finer the powder the smoother the tablet.

Some have not secured adhesion enough in the tablet for the reason that they have tried to make one diluent or base work satisfactorily with every formula, or by using the wrong strength of menstruum for moistening. Others have made the mass too soft, and been disappointed with the resulting product. If on mixing the active ingredients with the diluent and menstruum we find that the mass is not adherent enough, we must look for the remedy in two directions:—

1st. In so changing the diluent or base that we may thereby increase its adhesiveness.

2nd. In changing the strength or character of the liquids used to moisten, so as to bring about greater adhesion.

In the manufacture of tablet triturates many have failed from the simple reason that they have sought to use sugar of milk exclusively. This is no more than would naturally be expected from such a procedure, for while milk sugar serves an excellent and important part in the manufacture of many tablets, it is necessary often to combine it with varying quantities of cane sugar in order to secure the best results; while in making tablets like permanganate of potassium, the use of any kind of sugar is inadvisable, and recourse must be had to precipitated chalk or kaolin, and water used to moisten the mass. In making hypodermic tablets, pure powdered cane sugar alone should be used as a base, and alcohol to moisten. And if the sugar is fine enough and care is used, no difficulty will be found in obtaining a product that is excellent in appearance, and equaling those of the market in every way.

Tablets may thus be properly divided into four different classes:—

1st. Those in which cane sugar in its finest possible powdered form should be used as the base or diluent.

2nd. Those in which powdered milk sugar is used.

3rd. Those in which 5 parts of milk sugar and 1 part or more of cane sugar is used.

4th. Those in which precipitated chalk or kaolin should be used.

For moistening liquids the following are employed:—alcohol; alcohol 20 parts, and water 1 part; water; ether; chloroform.

Some recommend mixtures of ether and alcohol, and chloroform and alcohol, which will be found very useful sometimes, but it is difficult to see any advantage in using benzine, as is sometimes recommended.

The largest class of tablets are made with base or diluent No. 3, for example, tablets of calcium sulphide of bismuth subcarbonate, of bismuth subgallate, and of Dover’s powder. These, besides being representative of the largest class, are also the easiest to make.

The only tablets with which the pharmacist is liable to have any trouble are those containing extracts, fluid extracts, and tinctures. These may often appear troublesome from several causes:—

1st. The large amount of liquid ordered, as in the case of tablets containing tinctures.

2nd. Where the amount of solid extract exceeds one third of the bulk of the tablet, difficulty will be found in making a nice tablet.

In the first case, where the tincture is strongly alcoholic, it is best to mix it with a portion of the diluent, allow a portion to evaporate, then reduce to powder or smooth mass, and add the balance of the diluent when, if necessary, the mass can be moistened with alcohol and made into tablets. Sometimes the menstruum of the tincture is too astringent to admit of this treatment; in this case it is necessary to use an amount of fluid extract equal in medicinal strength to the tincture. By this method the advantage of the lesser bulk of the amount of fluid extract necessarily overcomes the difficulty. With this class of tablets pure sugar of milk will generally be found best, but sometimes they may be found too friable and break too easily. This may be remedied, and a harder tablet made, by using milk sugar and cane sugar in the proportion of 4 or 5 of milk sugar to 1 of cane sugar.

It will hardly be found possible to make nice tablets with solid extracts where the amount of extract exceeds one third of the weight of the tablet.
Another class of preparations which are sometimes called for, and can be readily made, consists of tablets composed almost entirely of the medicinal part. In this case it is necessary to rub the powder up with some adhesive substance like acacia, and moisten as in making a pill mass, then rub into the plate and otherwise treating as a tablet triturate. In this manner nice tablets can be made, and very easily. While this is not exactly a tablet triturate, being more in the nature of a lozenge, it is a very efficient way of making this class of goods. In fact, with a plate large enough, very excellent losenges can be turned out by this process. But on account of the cost of plates of this size, the losenge cutter may be recommended, as it is much cheaper, or easily improvised.

If the pharmacist will use care and judgment in this class of work, there is no possible reason why he should not be successful in making any possible combination of tablets triturates. The difficulties that arise cannot deters the working pharmacist, who believes in himself, from ultimate success. The material used in the experiment is not lost, but can be rubbed up thoroughly with a sufficient quantity of medicine and diluent to make the number of tablets required. Otherwise it could not be used, as it is readily seen that the amount of medicine is not evenly distributed throughout the tablets in the trial given.

In making tablets it is always best to make up an excess of mass, as it is much better to work with an excess than to attempt to work with an amount representing exactly the quantity desired.

In making such tablets as those of permanganate of potassium, and other substances that are decomposed more or less by organic matter like sugar or sugar of milk, kaolin is the best vehicle, and it is easily worked.

In some of the tablets similar to those in which the medicinal part composes the larger part of the tablet, it will be found necessary to use some adhesive to hold them together; for this purpose use acacia, and moisten very carefully with water.—Druggists' Circular.

THE OPium TRADE OF ASIA MINOR.*

Opium is perhaps the most interesting, the most valuable, and the most famous product of Asia Minor. This substance, which resembles a resinous gum, is extracted from the capsules of poppy-heads. Incisions are made in the capsules after the fall of the flowers, and the juice which runs from them is then dried and made up into blocks of various sizes. These are covered with leaves and sent in special bales to the market of Smyrna.

The poppy is usually cultivated in the central regions of Asia Minor on firm soil of sandy or chalky clay, richly manured. Several sowings are made throughout the course of the year, but the crops are grouped under two general denominations, the autumn and the spring crops. The autumn sowings are begun towards the end of the month of September, and produce the greater part of the harvest.

* From a report of the French Chamber of Commerce at Smyrna.
The seed is sown in fields which have been ploughed or dug up, and when the plants have appeared and many are destroyed in order to assure to each plant a clear space of about 75 centimetres. The earth ought to be stirred and hoed three times over before the time for picking the poppy-heads has come.

After the month of November the snow almost always covers up the young plant, which is thus preserved from frost and the severity of the winter until the snow melts; that is to say, until March. It then grows vigorously until it becomes from 1 to 1.5 metre in height. Each plant produces from 5 to 30 globular capsules, which are generally oval in form. The flowers are large, solitary at the top of the ramifications, and composed of four or five petals set in the form of a cross, and crumpled until they expand. They are of all shades from white to red. When the capsule is ripe it takes a pale yellow tint. This is the moment for making the incisions. They are always made at sunset; the juice which oozes from them in the form of tears is collected next morning, at dawn, in shells. It is then dried and moulded into the form of blocks, which are wrapped in leaves of the same plant. From its first appearance until the moment of harvest, the plant is exposed to all the intemperance of the weather, excess of rain, or drought, of cold or heat, violent winds, etc., and it is thus peculiarly liable to be injured on the nights which precede the incision of the capsule.

The seed is sown two or three times in spring, between the beginning of February and the end of April. This crop requires greater uniformity of weather especially frequent rains. The consequence is that the spring sowings are more delicate, and their product is sensibly inferior to that of the autumn crop.

The blocks are left to dry, and are then arranged in high baskets containing about 75 Kilogs., with certain leaves which have the property of keeping the opium in good condition, and of preventing the blocks from sticking to one another. The bales are then forwarded to Smyrna and Constantinople to be sold there to exporters. Turkish opium has produced during the last fifteen years an average of 6000 bales. One single year, which was absolutely exceptional, produced 11,000 bales. But this year we have only 3000, a figure just as abnormal as the preceding.

These are the various varieties of opium and their respective values:

1. Malatia, Tokat, Zihth.—Quality extremely fine, and the paste much appreciated by Chinese smokers for its delicate flavour. Amount of morphine very small, varying from 8 to 11 per cent., which is only obtained by means of a special selection.

2. Boghadich.—The best quality of Turkish opium, paste delicate and fine, greatly appreciated, especially by the smokers of Central America.

3. Yerli.—All opium which is grown in the neighbourhood of Smyrna is called Yerli. It is less valued than that of Boghadich, but is as rich in morphine. This is the quality which is used for drugs and in medicine.

4. Chaise.—This kind is so like that of Yerli that it may be included in the same category.

5. Salonica.—The cultivation of opium at Salonica is of relatively recent date. It has greatly extended, and produces about 800 bales per annum, half of which, of very fine quality, is more appreciated than even the Boghadich.

6. Karabissar.—This is the district which produces the most opium, and supplies, on a large scale, the trade of England, America, and Holland. The quality of this variety is very good; the morphine varies from 9 to 12 per cent.

7. Adeth.—Average quality brought from all parts of the interior. The Turkish word “adeth” means “usual.” It represents the ordinary type, which is easily sold for China and America, and the amount of morphine is almost uniformly 9.5 per cent.

8. Chinqui.—This name is given to a quality of opium from various parts of the interior. It is opium mixed with foreign matter; it contains morphine sometimes to the extent of 9 per cent.

9. So so.—Under this name are designated those opiums which are bought in the condition in which they arrive from the interior. There is a mixture of five kinds and of Chinqui. The morphine is from 9 to 11 per cent. It should be noted that mousy opiums of bad appearance, which are rejected, are often found figuring afterwards in the category of the “So so’s.”

These are, approximately, the quantities exported each year:

or cases representing, at the average price of 48 francs the kilogramme, 11 millions of francs.

The permanent stock, at the end of the season, which closes on the 15th of June, is valued approximately at 1000 bales between Smyrna, Constantinople, and the producing districts. The maximum price of opium of late years has been 40 francs the kilogramme, and the minimum price to which it has fallen has been 18 francs; but this fall only occurred once, and lasted but a very short time. In any case we are very far from that period when this article, which used to play a preponderating part in the export trade of Smyrna, sometimes reached very high prices indeed. The price used to go up and down, producing great profits and serious losses. But the speculative spirit which used to mark the opium trade has entirely disappeared, the variations of price are slight, and only follow the normal law of supply and demand, in consequence of the extent of the crops and the requirements of the consumer.—Board of Trade Journal.
Editorial Department.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to "Street Brothers," 5, Soho Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased. Orders and money orders must be made payable to "Street Brothers."

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Brambridge, 17, Bloomsbury Square, London, W.C.

PHARMACEUTICAL TESTING.

The circumstances of the case reported at page 536 afford an instructive illustration of the desirability of testing the various materials which the chemist has to deal with in the ordinary course of his business. Ordinary tradesmen are responsible for the nature and quality of the articles they sell, and though possessing no capability of applying tests other than those acquired by familiarity with the goods they deal in, they are liable to prosecution under the Food and Drugs Act if their wares are not what they are represented to be. In the case of chemists the necessity for giving attention to this matter is still more imperative. The very title under which they carry on their business, and to the use of which they claim exclusive right, conveys the idea that they are able to detect impurities in the articles sold by them. That capability should be more generally exercised by chemists, not only for the sake of enabling them to guarantee the quality of every article they sell and to inspire the public with confidence in them, but also for the sake of protecting themselves against the unpleasant consequences which may result from inadvertently selling a defective article.

At the present time, when factory-made chemicals and pharmaceutical preparations enter so largely into the stock-in-trade of the chemist, such precautionary measures are the more indispensable. Even articles made by the chemist may deteriorate by long keeping, and in such cases periodical testing is the only means by which absolute certainty as to quality can be secured. Nothing less than that ought to satisfy the conscientious chemist desirous of maintaining his reputation and of avoiding the risk of being charged with selling adulterated or defective articles. The excuse sometimes made for neglecting to examine articles, that too much time would be taken up, is not entitled to much consideration, for the necessary operations may be carried out in a very simple manner in the greater number of instances, and the chemist has always at hand appliances which can be turned to account for the purpose. Not long since Mr. Barnard Proctor published an excellent manual of pharmaceutical testing, in which he described methods of examining almost all the articles which are ordinarily met with in a chemist's shop. He showed, also, how such work can be carried out, with the materials and appliances usually to be found at the dispensing counter and by such operations as are in daily use in the work of dispensing. His opinion is that every chemist should test his chemicals occasionally, to see that their quality is up to the required standard. We fully endorse that opinion, and would impress upon all chemists the great importance of giving attention to it.

LECTURES ON Diphtheria.

Mr. Lennox Browne gave the second lecture of this course on Tuesday at the Central London Throat, Nose, and Ear Hospital, when "Doubts in Diagnosis as determined by clinical observation," were considered. Commenting on a general confession on the part of recent writers that the clinical distinctions between true and false diphtheria were so difficult, and even impossible of differentiation, as to be only settled by a bacteriological examination, the lecturer refused to accept such a wholesale surrender of the clinical fortress. He willingly admitted, however, that it was only by careful comparison of both physical and functional symptoms of the varieties of membranous sore throat, which were characterised by certain micro-organisms alone or associated with the diphtheritic bacillus, that medical men could hope to form a more accurate opinion than at present obtained at the bedside of the patient, and so to reduce the admittedly large proportion of cases treated as diphtheria which were not of that nature. Until that was done, not only were the returns of mortality very misleading, but the effects of treatment, whether by antitoxic serum or any other remedy, could not be properly determined.

The lecturer then proceeded to discuss the differential diagnosis from the various manifestations of the membrane in the throat, and also the varying effects on the general system. These were naturally of a technical nature, but they clearly indicated that by pursuing the lines laid down, there was a possibility of arriving at a more satisfactory degree of accuracy.
ROYAL SOCIETY.

In the course of a somewhat lively correspondence in the pages of the Times, "A Critic" tells "a little story of the actual management of the Royal Society." The latest recipient of the Rumford medal, it is stated, asked the treasurer, half in jest, what had become of the cheque for £60 which usually accompanied the medal. The treasurer was surprised and said no such payment was ever made, being confirmed on this point by the secretary. A week or two later, however, the treasurer, addressing the medallist, informed him that he had been right about the money, though it had not been paid on the last three occasions. The medallist said the Society might as well keep the money, as its funds seemed low, but the treasurer said this could not be, as the Rumford funds were trust funds. He therefore proposed to pay the medallist "£60" instead of £80. Comment upon such peculiar financial methods is unnecessary.

FRIGOTHERAPY.

According to the British Medical Journal, M. Raoul Pictet has extended his application of low temperatures to the treatment of dyspepsia, under the name of "Frigotherapy," and being a sufferer from indigestion, has ascertained, by experiments upon himself, that exposure to a very low temperature for several minutes relieves indigestion and excites hunger. By repetition of the treatment his stomach affection was entirely cured.

DEATH OF PROFESSOR FLÜCKIGER.

The Editor desires to give expression to his sense of obligation to Professor Schmer, for having so promptly responded to his request to furnish an obituary notice of his former teacher and predecessor at the University of Strasburg.

SCIENCE PROGRESS.

MISCELLANEOUS NOTES.

At the annual business meeting of the north branch of the Chemist and Druggist Association of Ireland, on Thursday, December 6, Sir James H. Haslett, J.P., was elected president for 1896, and it was decided to hold the annual social meeting in January, a sub-committee being appointed to carry out the arrangements.

It is proposed that the London County Council shall establish a municipal laboratory where, in cases of suspected cholera and diphtheria, bacteriological examinations shall be conducted.

The Metropolitan Asylums Board has decided that its managers shall accept the offer of the Royal College of Physicians and Surgeons to supply antitoxin for the treatment of diphtheria. Public funds will be therefore applied to maintain a number of horses for the supply of serum.

The death of Arthur Cowper Ranyard, editor of Knowledge, occurred on Saturday last, after a brief illness. Mr. Ranyard was a skilful astronomer and the intimate friend of the late Richard A. Proctor.

Mr. G. T. W. Newsholme, member of Council of the Pharmaceutical Society, has been re-elected unopposed as a member of the Sheffield Board of Guardians.

The Standards Department has been supplied with a new set of standard metric weights, constructed of iridio-platinum and ranging from 500 grammes to 0.01 grammes. A primary standard weight of 10 grammes, verified at the Bureau International des Poids et Mesures, has also been provided.

H. W. Collier, son of Mr. H. Collier, pharmacist to Guy’s Hospital, has obtained at the recent examinations of the University of London the degrees of Bachelor of Medicine and of Bachelor of Surgery.

At the recent Scholarship examinations at Cambridge, Stanley de Jersey Lenfestey—third son of Mr. W. Giffard Lenfestey, a member of the Pharmaceutical Society, and for some years local secretary at Faversham—was elected to an open mathematical scholarship at Peterhouse.

At a meeting of the Liverpool Medical Institution on the 6th inst., Dr. Caton reported two remarkable cases of lead poisoning arising from the use of water containing lead, amounting in one instance to two, and in the other to as much as three grains in the gallon.

In celebration of the quincentenary of the Salters’ Company, the Court of the Company has arranged a scheme for establishing Research Fellowships in Chemistry in connection with the City and Guilds of London Institute, in addition to those at St. Thomas’s Hospital and the Research Laboratory of the Pharmaceutical Society.

It is reported that as many as one hundred and fifty persons, living at Freiberg, in Saxony, are suffering from the effects of arsenic contained in breakfast rolls. An inquiry is being conducted.

PROVINCIAL TRANSACTIONS.

LIVERPOOL CHEMISTS’ ASSOCIATION.

A meeting of this Association was held at the Royal Institution, Liverpool, on Thursday, December 13. The President, Mr. J. J. Smith, took the chair.

Mr. T. H. Wardleworth showed specimens of Garcinia kola, which the New authorities had identified as kola, though he himself was disposed to think they belonged to the monozygote family. He would probably refer, to them again at the next meeting.

Dr. C. Syme expressed the opinion that, in view of the changes that were proposed in the next edition of the Pharmacopoeia, pharmaceutical associations in the provinces should take up the matter, and suggested that the Liverpool Association should devote an evening of the session to a discussion of the subject.

An address was then given as follows:—

THE DISTRIBUTION OF PLANTS.

BY PROFESSOR R. J. HARVEY GIBSON, M.A.

After explaining that distribution is not haphazard, but is controlled by certain influences and is in obedience to certain laws and conditions, a chart was shown in which the various influences were set forth—

1. Environment—\( a \) Inorganic: temperature, moisture, light, soil; \( b \) Organic: other living things, symbiosis, neighbours, parasites, man; \( c \) Powers of dispersal; \( d \) Barriers to migration; \( e \) Past distribution of plants.

Tropical plants have intense vitality, and form dense bushes and forests of high trees. In warm temperate regions there are no palms and heat-loving plants, but wheat and tropical grains, olives, etc. In temperate regions shrubs and greenhouse abound, and wheat and other northern grains grow. The sub-Arctic zone produces berries and pines, and the Arctic zone mosses, lichens, saxifrages, etc. Moisture and temperature together determine distribution.

The influence of moisture was next referred to. In very dry regions succulent plants, which lay up stores of water and are covered with a leathery integument to prevent evaporation, are found. A wet condition produces an absence of leathery, spiny, and dry characters, and also of hair, bloom, and wax. A tropical fernery is typical; ferns seek shade and dampness. The influence of neighbours is obvious, and a struggle for existence is continually taking place. The annual, in competition with the perennial, becomes crowded out.

Man produces and introduces, sometimes assisting and sometimes limiting distribution. The various means by which seeds and fruits are distributed were described, and examples shown.

Coming to barriers to distribution, a chart was shown pointing out that in the struggle the higher plants were beating others. Views of Bournemouth Valley, and of parts of Lancashire were shown. In the former place tropical trees grew in not very ancient times, and in the latter, remnants of tree ferns and fossils of reptiles had been found unlike anything now on the earth. The lecturer then proceeded to deal with the astronomical and geological evidence of the Ice Age of 250,000 years ago, and pointed out that, from the fact of there being no plants peculiar to this country,
it was evident that it had once been connected with the Continent.

The lecturer concluded with illustrations and descriptions of the different types of plants which occur principally in the different parts of Great Britain, and the address was copiously illustrated throughout with lantern slides.

A vote of thanks was accorded, and Professor Harvey Gibson afterwards replied to various questions.

Scottish Transactions.

EDINBURGH CHEMISTS', ASSISTANTS, AND APPRENTICES' ASSOCIATION.

The second meeting of the seventeenth session was held in the Pharmaceutical Society's House, 36, York Place, Edinburgh, on Wednesday, December 12, at 3.15 p.m. Mr. Alexander Sutherland, President, in the chair. There was a very large attendance.

The minutes of the last meeting were read and approved.

The following papers were read:—

NOTE ON CARBOLIC ACID.

BY GEORGE COULL, B.SC.

About six weeks ago a complaint was made to me that the carbolic acid supplied to a certain institution had caused one of the medical staff to contract an eczematous affection on his hands, whereas the use of another acid enabled the operator to work with it without any ill-effects occurring. Some five samples (all of them of different manufacture) were, therefore, procured, and a detailed examination made. It is on the material acording from this investigation that the present note is founded.

The two most commonly used tests for valuing carbolic acid are its boiling point and its melting point, besides which an approximate assay of the acid may be made by means of solution of bromine.

The samples examined were designated as follows:

2. Pure carbolic crystals or absolute phenol. M. pt. 40° C.
3. Absolute phenol.
4. Acid carbolic, purest.
5. Absolute phenol. Solid at 104° F.

On the label of No. 3 was kindly given a definition of absolute phenol, viz., "Absolute phenol consists of carbolic acid in a state of extreme purity." The label of No. 5 also stated that it was carbolic acid in a state of great purity and free from water, while across No. 4 was impressed the touching, and now, alas! too familiar legend—"Made in Germany."

Boiling Point.—The boiling point of carbolic acid given in the British Pharmacopoeia is "not higher than 371° F. (188° C.)," and in the United States Pharmacopoeia "not higher than 188° C. (370°-4° F.)." From a comparison of the boiling points in other pharmacopoeias as shown in Squire's Companion (16th ed., p. 16), it is seen that with the exception of the Codex (187°-189°) these are the two highest allowed. The others mostly average 184°; the Danish, German, and Russian standards are the most stringent in requiring a low boiling point, the latter two being 178°-182°, while the former is 173°-180°. The boiling point stated in different text-books, etc., also varies to a certain extent, although the figures there given are supposed to apply to a pure definite chemical body. Morley and Renssen give it as 180°, Bernthsen (2nd ed.) and Thorpe's Dict. as 181°, Watts' Dict. as 181°-5°, Allen's 'Org. Anal.,' and Roscoe and Schoenlemer as 182°, and Richter as 183°.

It is possible that these differences may be accounted for by some observers working with a purer acid than others, or by some using a more refined method than others. These discrepancies indicate the necessity for the greatest care and accuracy in all chemical work, more especially where there is any likelihood of a communication being accepted as authoritative. It is further evident that there will always be variations in the observed boiling points of organic substances until there is a definite fixed method of determining this constant, which all chemists must follow.

In very accurate determinations, beside the correction for the cooling of the mercury column not in the flask and for barometric pressure, there is another recently noticed by Lord Kelvin for the expansion of the thermometer bulb caused by the pressure of the mercury. For pharmaceutical purposes it may be assumed that these corrections are unnecessary refinements. I shall, therefore, simply state what occurred when the acid was heated in a small distillation flask with the bulb of the thermometer so placed that it was completely surrounded by the vapour, but not dipping into the acid. The thermometer used was lent to me by Dr. Dobbin, chief assistant to Professor Crum Brown, and may be relied upon as being accurate.

After melting, in the case of every sample of acid tested, the temperature rose rapidly to about 177°, and then more slowly to 180°, at which temperature the thermometer remained steady until the great bulk of the acid came over, and then it slowly rose to 193°-197°, the highest point being reached when the bottom of the flask was dry. This high temperature may have been due to a superheating of the vapour, or caused by the presence of a very small quantity of one of the cresols. There are three isomers of this homologue of phenol, the ortho, meta, and para modifications, whose boiling points are respectively 188°, 201°, and 198°.

It will be seen that determining the boiling point of commercial carbolic acid in the ordinary way does not give a definite result, owing to the circumstance that it is not absolutely pure. The thermometer bulb was therefore immersed in the acid, and another trial made, when it was found that all the acids boiled at the temperature 181°-181°-5°, until fully 80 per cent. was over, and the bulb no longer dipped into the liquid, but was surrounded by vapour. This, I suggest, should be taken as the temperature at which the acid boils, being more constant than the temperature of the vapour given off.

Melting point.—In regard to the melting point, the British Pharmacopoeia occupies a still more humiliating position in demanding that carbolic acid shall melt at a temperature not lower than 91°-5° F. (33° C);
This is lower than that of any other pharmaeopoeia. Squire (ibid.) compares the melting point also as given in various pharmaeopoeias. The Swiss and French require the highest melting point, namely, 42° (the m.pt. of absolutely pure phenol); some give a range of temperature between the limits of which the acid should melt, which I think is a mistake. It ought to be stated, as in the U.S.P. and B.P.—not lower than a certain temperature—anything above that, of course, could not be taken exception to.

The melting points of the above-mentioned samples were taken in the ordinary way by means of a capillary tube (containing the substance) fastened to the bulb of a thermometer and immersed in water. The following are the results—

The determinations were effected with a Fahrenheit thermometer, then calculated to the Centigrade scale. It seems to me that the melting point is a more definite, reliable, and easily applied test than the boiling point.

**Assay of Carboilc Acid.**—Landolt,* in 1871, first made use qualitatively of the reaction between bromine and phenol as a means of proving the presence of carboilc acid in a well-water, as little as 1 in 43,700 being capable of detection. In 1877, Koppeschaar† devised a volumetric process for the determination of phenol based on the same reaction, but instead of using bromine water he employed a solution of alkaline bromide and bromate, from which the bromine was set free by hydrochloric acid. An excess of the previously standardized bromate solution is added to a known quantity of carboilc acid dissolved in water, hydrochloric acid is added, and then potassium iodide in excess; the excess of free iodine and, therefore, of bromine, is then ascertained by titration with sodium thiosulphate. The amount of free bromine is to be deducted from the total bromine added; this gives the quantity that has replaced part of the hydrogen of the phenyi group according to the following equation

\[ C_6H_5OH + 3Br_2 = C_6H_5Br_3OH + 3HBr. \]

It has been shown by Weinreb and Bondit that the hydrogen of the hydroxyl is also replaced by bromine, forming tribromophenol bromide. But although this takes place it is said not to interfere with the usefulness of Koppeschaar’s process, for tribromophenol bromide under the action of potassium iodide and hydrochloric acid gives up its hydroxylic bromine, and tribromophenol is the final product of the reaction. Hence the above equation holds good, and is adopted in determinations of carboilc acid; it shows that one molecule (94 parts) of carboilc acid react with three molecules (480 parts) of bromine.

It may be mentioned that the formation of tribromophenol is promoted by the use of excess of bromine and shaking for half an hour. The experiment was tried of shaking for five minutes only, with the result that the figures came out about one per cent. less than in the above table.

This high result is possibly due to the formation of a small quantity of a higher substitution product, or it might be caused by the incomplete decomposition of the tribromophenol bromide.

**Conclusion.**—From the results stated above, it will be observed that carboilc acid may be obtained commercially, and, it may be added, at a moderate price, in a condition of purity far in advance of what the B.P. demands. I would therefore suggest that our standard be raised, by requiring that the melting point be not lower than 102° F. (38°-8 C.), and that the boiling point be not higher than 359°-6 F. (182° C.), the bulb of the thermometer being immersed in the acid. These two constants are not more exacting than necessary, as it has been demonstrated above that carboilc acid can be easily obtained having these characters. The desirability of including Koppeschaar’s process for the volumetric determination of the acid in presence of water, I would leave for further consideration. In my hands it has always registered too high; further experiment may elucidate the cause of this, and if the disturbing factor can be discovered the process might eventually be adopted. At present, as the United States Pharmacopoeia says, it gives only an approximate value of the acid.

**A Novel Impurity in Chloral Hydrate.**

**By Alexander Gunn.**

My attention was recently drawn to a bottle of chloral hydrate standing on a shelf among others. The bottle was of white glass and showed yellow spots among the contents, not only where the light struck, but in the hidden parts as well. Only one bottle showed the spots. The crystals were moist and distinctly acid to litmus. The yellowness gave the crystals the appearance of yellow crystals, but it was found to be only superficial. The yellow crystals were separated, and gave evidence of free hydrochloric acid. The appearance suggested the result produced by the action of hydrochloric acid on iron, and, on testing for this metal, its presence was at once demonstrated. On placing a quantity of the ordinary white crystals in a test tube, and adding a minute fragment of iron, it was found that, after standing a week, there was a production of yellow patches exactly

* Berichte, iv., 1770 (Year Book, 1572, 201).

* U.S.P., 1890, p. 10.
similar to those observed in the stock bottle. A minute black substance was found among the yellow crystals, but was lost before it had been examined. There seems little doubt, however, that the colouration was due to the accidental presence of a particle of iron in the stock bottle.

---

**Note on a Seidlitz Powder.**

**By Alexander Gunn.**

A box labelled "Improved Seidlitz Powders" was handed to me for examination. On proceeding to dissolve the contents of one of the blue papers in water, it seemed to take a long time, and, on looking closely at it, there was evidence of decomposition and a heavy precipitate was falling. On applying heat, there was active effervescence, the precipitate became denser, and rapidly subsided on removing the heat. The precipitate was found to be magnesium carbonate. On heating some of the original powder on platinum foil, there was no sign of charring. Sodium, sulphuric acid, and carbon dioxide were found. The powders, therefore, consisted of magnesium sulphate and sodium bicarbonate. The white papers contained tartaric acid. Evidently there had been a mistake, or else it was a bold attempt to cope with the cutting system and its cheap prices. One wonders that the makers should expect the unusual effect of trying to dissolve the contents of the blue paper to pass unnoticed. My thanks are due to Messrs. Fletcher, North London Chemical Works, in whose research laboratory this and the foregoing note were prepared.

**Codeine Sulphates with Hydrobromic Acid.**

**By William Duncan.**

The following prescription was handed to me for an explanation of the decomposition which ensues on dispensing:

B Codein sulphata ..........................ogra.ix.  
Acid hydrobromici .................. 51.  
Liq. strychnina .................... 2.  
Glycercini .......................... 3.  
Inf. rosae acid .................. ad. 3 1/2.  

Concentrated infusion was used. On dissolving the alkaloidal salt in water and adding the hydrobromic acid, abundant crystallisation resulted. The crystals re-dissolve on heating, but again separate out on cooling. On adding the other ingredients of the prescription the crystals slowly and almost completely re-dissolve, the glycercin probably exerting a powerful solvent action. The crystals, washed free from adhering acid, were found to be neutral to litmus, readily soluble in water, but only sparingly in dilute hydrobromic acid. Chemical examination proved them to be codeine bromide. It seems, therefore, that codeine bromide resembles strychnine and other alkaloidal salts in being much less soluble in acid than in water. It is therefore advisable in dispensing alkaloidal salts with excess of acid to put on a "Shake the Bottle" label to avoid any risk from unforeseen crystallisation.

---

The reading of the papers was followed by a discussion, taken part in by Messrs. Boa, Coull, Duncan, Hill, McKewan, Sutherland, and White.

Mr. Hill then exhibited and described an *Aspidistra lurida*, which had flowered in the Society's House. It showed the curious dull-purple flowers, with bell-shaped eight-cleft perianth characteristic of this genus of the Zingiberaceae. The flowers arise from the underground rhizome on one-flowered short peduncles, and seem to be resting on the soil in a position well adapted for fertilisation by the agency of snails, as was proved by Dr. John Wilson a few years ago. Though the plant is a very common one in cultivation, the flowers are not often seen.

Mr. Hill also read an amusing paragraph from a book on "Old Violins and their Makers," which had been sent by Mr. D. B. Dott. The interest of the paragraph consisted in its extraordinary statements with reference to alcohol used in making varnish. One specimen was as follows: "If wood spirit has been added, it combines so perfectly that its presence cannot be determined by any known process; but this latter does not injure the solving power of the alcohol."

On the motion of the chairman, a cordial vote of thanks was awarded to the authors of papers, and to Messrs. Hill and Dott, and also to Mr. Duncan, by whom the proceedings had been arranged.

---

**Glasgow and West of Scotland Pharmaceutical Association.**

At the meeting held on Thursday, the 13th inst., Mr. John McMillan, Hon. Vice-President, in the chair, the following paper was read—

**Notes on Compound Syrup of the Phosphates.**

**By Wm. Watson.**

Being persuaded that there is great diversity in the quantities of iron and lime phosphates present in commercial samples of this syrup, I decided to endeavour to assay the same. Two samples in particular which I have come across lately, bright in appearance, but with little or no astringent taste in them led me to think on this subject. The demand for cheapness, as also the want of an official recognition, leaves an open way for the sale of worthless imitations of this valuable medicine. In referring back to the *Pharmaceutical Journal*, I found that eighteen years ago Mr. Howie gave an able and exhaustive paper on "The Phosphate Syrups." On that occasion, he found by volumetric determinations that out of nine samples, the quantity of ferric phosphate varied from 169 gr. to 1118 gr. per fluid 3 1/2 of syrup. As to the lime phosphate, which was more indefinite owing to the greater difficulty of separating it from the sugar, his determinations indicated as from 58 gr. to 220 gr. per fluid 3 1/2 of syrup. The original syrup was at that time understood to contain 1 gr. of phosphate of iron, and 2 1/2 gr. of phosphate of lime in each fluid 3 1/2. But it was found that 1 1/2 gr. of phosphate of iron, and 2 grs. of phosphate of lime were more correct figures. Again, I find in the 1890 edition of "Squire's Companion," that in nine commercial samples recently tested, the quantity of phosphate of iron varied from 19 gr. to 66 gr. and lime phosphate from 5 gr. to 16 gr. per fluid 3 1/2 of syrup.

Since 1876 there has been great progress made in the process for the manufacture of this, as also Easton's Syrup. The old process of precipitating the phosphates, where it was impossible to prevent the
Parliamentary and Law Proceedings.

PROCEEDINGS UNDER THE PHARMACY ACTS.

ACTION AGAINST A MEDICAL BOTANIST.

At Oldham County Court, on Thursday, December 13, before Judge Jones, an action was brought against W. Schofield, medical botanist, Ashton Road, Oldham, by the Pharmaceutical Society for having sold poison, he not being a properly qualified person under the Pharmacy Acts.

Mr. Grey, counsel, stated that on August 27 and September 1, Arthur Foulks called at defendant's shop and purchased on each occasion a bottle of cough mixture, for which he paid 7d. The contents were analysed by Mr. Eastes, analyst, and the mixture was found to contain a quantity of opium. Evidence was given to the effect that he had been an herbalist for thirty years, and had always guarded against selling scheduled poisons. He denied having committed the offence.

His Honour said that this case was an action brought under the Pharmacy Act, which was passed for the protection of the public, so that no unqualified person should be allowed to sell what were poisons. In this case it had been proved that the defendant had sold a mixture containing opium. That being so, the defendant had offended under the Act on two occasions. It was the duty of the Pharmaceutical Society, under the provisions of this Act, to send persons round to ascertain whether people selling poisons were qualified, and if not it was the duty of the Society to enforce the Act. The defendant must pay the full penalty of five pounds in each case, together with the costs.

ACTION AGAINST A GROCER.

At the Aberavon County Court, on Monday, December 10, before Judge Owen, S. O. Pegler, grocer, Aberavon, was sued by the Pharmaceutical Society for having sold poison, he not being a properly qualified person under the Pharmacy Acts. Mr. R. E. Vaughan Williams, barrister, appeared for the Society.

George Pitt Pidgley stated that, on October 21, he went to defendant's shop and purchased some groceries, after which he asked for a bottle of Fellow's Syrup. Defendant said he did not keep it, but, when requested, sent out for it, and it was included in the bill for the groceries, which was duly received by defendant.

Mr. F. Gardner, solicitor, urged in defence that defendant was in the same position as the keeper of a refreshment room, who had no licence to sell beer, but could send out for it for his customers. If he had made no profit on the transaction, he further urged that the bottle was obtained by a trick, but the Judge remarked that people who broke the law could not be caught sometimes without tricks.

His Honour then said this was an action by the Pharmaceutical Society against a grocer, claiming (under information) a penalty of five pounds for (he being a person not a pharmaceutical chemist or druggist) selling a compound which was known to be poisonous and containing a large amount of strychnine. The man (Pidgley) on behalf of the Pharmaceutical Society, went in and asked for a bottle of the poisonous stuff called "Fellow's Syrup," and was told they did not keep it, but he was told if he called again, later in the day, it would be got for him. He ordered the syrup, and also some other small things, and when he called again, Mr. Pegler put the thing up and gave him a bill, headed "Bought of S. O. Pegler."
bill included a charge of 3s. 3d. for the syrup. Now it was said that Pegler did not sell. It might be a hard case, but the Act of Parliament was a wise one; it prevents people buying poisonous medicines, which many "patent" medicines were, containing a great deal of poison, and exceedingly dangerous to life. If he held that this was not a sale, he did not know what it was. The Act of Parliament was a good one. It was said it was a case from which defendant derived no profit, but yet he sold the thing, as was shown by the bill. He must give judgment for the claim for five pounds and costs.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACTS.

LAUDANUM DEFICIENT IN ALCOHOL.

At the Highley Police Court on December 7, before Alderman John Briggs and other magistrates, Arthur Noble Kersehaw, chemist and druggist, Corn Mill Bridge, was summoned by Arthur Randerson, the local inspector under the Food and Drug Acts, for selling laudanum not of the substance and quality demanded by the Act. Mr. A. M. P. Randerson, solicitor for the defendant. Mr. Randerson stated that on November 1 he bought a quantity of drugs from Mr. Kersehaw for the purpose of analysis, samples of which were sent to Mr. Allen, county analyst, of Sheffield, and all were found to be correct except the laudanum, which contained only half of the alcohol which would have been present had the laudanum been prepared according to the directions of the British Pharmacopoeia. It appeared that Mr. Kersehaw had prepared a gallon of laudanum at a time and kept it in a gallon jar. It was sold out in very small quantities, and by the constant removal of the cork and the heat of the shop some of the alcohol had apparently evaporated, but the medicinal part of the drug was there in proper quantity. The Bench thought that the offence was due to a little want of care, and only imposed a nominal penalty of 5s. and costs.—Bradford Observer.

ADULTERATED OLIVE OIL.

At the Worship Street Police Court, on December 8, Messrs. Walton, Hassell and Port, oilmen, etc., possessing shops in various parts of London, were summoned by the Vestry of St. Leonard, Shoreditch, for having sold in two instances at their shops in St. John's Road, Horton, and Kingsland Road, a certain drug—i.e., olive oil—which was not of the nature, substance, and quality demanded. Mr. Robinson, LL.D., vestry clerk, prosecuted; and a solicitor whose name was not given defended. The purchases at the respective shops were proved by a sanitary inspector and his agent employed by the vestry, and the analyst's certificate handed in showed that the article sold in response to a request for "olive oil" was adulterated with vegetable oils to the extent of 50 per cent. Dr. Bryant, medical officer of Shoreditch parish, was also called by the prosecution to show that as a "drug" olive oil was entered in the British Pharmacopoeia, and that the substitution of vegetable oils would be wholly opposed to medical intention. The witness was cross-examined as to whether the vegetable oils referred to might not be nut oil. He could not say, but was positive nut oil of any character would not be a permissible substitute for olive oil. It being suggested that the adulterating article was cotton-seed oil, the defence denied it. The article known as olive oil should be olive oil. The defence suggested that the article sold was what was commonly sold as salad oil, but admitted that, olive oil having been asked for, there was no answer to the charge. To prove that nothing injurious had been sold to the public, as the article in question was the ordinary commercial oil, Mr. Henry Joseph Hassell, one of the defendants, was called. He said the firm had seventy shops in London, with a manager for each. The article "nut" oil was perfectly pure, and cost £38 to £40 per ton. He invoiced it from the firm's warehouse to the shop managers as "salad" oil. That was done because the public asked for salad oil, and "olive " oil was an unknown article—"a cavil to the multitude." Cross-examined as to why, if nut oil was a pure article, it contained 50 per cent. of olive oil; the witness said the statement was untrue, and the analysis incorrect; there was no olive oil at all in the article. He was aware that the Italian Chamber of Commerce had taken up the matter and complained of the substitution of other oils for olive oil as affecting the export. He denied that the article was cottonseed oil, but admitted that cotton-seed oil was largely used, and was one of the "foreign fats" frequently worked up into butter. After a lengthy hearing, Messers. Walton and Co. were ordered to pay £10 fine in respect of the first summons, and £5 fine in respect of the second.—Times.

WHITE WAX OR PARAFFIN WAX?

On Thursday, December 13, at the Edmonton Petty Sessions, before a full bench of magistrates, Stephen Bately, chemist and druggist, of 692, High Road, Tottenham, was fined £1 and £2 12s. costs for selling as white wax an article adulterated with 85 per cent. of paraffin. Mr. Beale, solicitor, appeared to prosecute, and Mr. Avery defended. From the evidence it appeared that on November 8 the inspector of the Middlesex Council purchased at the defendant's shop sixpenny-worth of white wax, which on analysis proved to be contain 85 per cent. of paraffin. It was stated that white wax was used as a medicine in the making up of pills, and should be pure bleached beeswax. When pure it cost about 5s. a pound, whereas paraffin-wax could be purchased at 5d. For the defence it was contended that the wax was not sold as pure.—Daily Telegraph.

POISONING CASES AND INQUESTS.

POISONING BY LAUDANUM.

Thomas Grove, aged 45, died at Wolliscote on Saturday, November 24, from the effects of laudanum, self-administered. Verdict: "Suicide whilst in a state of temporary insanity."—Worcester Journal.

AN OVERDOSE OF NARCOTICS.

James Swanson Cobb, aged 73, a retired surgeon dentist, suffered from sciatica and gout, and was in the habit of relieving pain and procuring sleep by taking chloral hydrate and morphine lozenges. On Tuesday, December 11, he was found unconscious and suffering from symptoms of narcotic poison. Death ensued on the Wednesday morning, and an autopsy clearly showed it to be due to narcotic poisoning. Verdict: "Death by misadventure."—Morning Advertiser.

POISONING BY OXALIC ACID.

Solomon Hills, aged 55, died at Taunton on Saturday, December 8, from the effects of oxalic acid, self-administered. Verdict: "Death by taking oxalic acid during temporary insanity."—Somerset Herald.

POISONING BY LAUDANUM.

John Emmerston, aged 37, was found dead in bed on Friday morning, December 14, from the effects of laudanum. Verdict: "Temporary insanity."—Times.

POISONING BY CARBOLIC ACID.

Joseph Stananought, aged 46, died on the way to the Charing Cross Hospital on Friday, December 14, from the effects of carbolic acid, self-administered. Verdict: "Suicide whilst of unsound mind."—Times.
Reviews and Notices of Books.

The sections of this work devoted to the consideration of pharmaceutical operations are practically identical with the same sections of the second edition. They contain a mass of valuable information, and furnish the pharmacist with an extremely useful account of the principal forms of apparatus employed in the various operations, and the manner in which they are used. Both the pharmacist and the student of pharmacy may study with advantage the chapters devoted to filtration, distillation, percolation, etc. They will be found, in the main, to be fairly well up to date, although occasionally useful adjuncts to the dispensing counter are missed. Thus, under the name "koneels" a form of the Morstede cachet apparatus is described, but the very useful little graduated glass tube with vulcanite plunger for measuring (instead of weighing) powders has been omitted. Considering that the work is apparently designed principally for retail pharmacists, it is to be regretted that neither amongst the stills or presses described is one really suitable for a laboratory in which space is limited.

This objection cannot be urged against the chapter on percolation, which is eminently practical. In fact, it is just in the carrying out of pharmaceutical operations that the author is evidently most at home; in his definitions he is not quite so happy. Evaporation cannot surely be defined as the separation of a volatile liquid from one which is less volatile (def. 1), and distillation does not necessarily involve the separation of two liquids (def. 2). Nor are the two following definitions (3 and 4) as precise as they might and should be. The manufacture of granulated effervescent salts has increased in this country, at least, enormously, and it is quite practical for the retail pharmacist to make the majority of them economically, in small quantities as required. But probably neither retail or wholesale druggists would attempt to mix the dry powders with tartaric acid, sodium bicarbonate, and alcohol, press the pasty mass through a sieve, and dry the granules.

The glossary is a new feature in this edition of The Practice of Pharmacy, which will undoubtedly be of much service to a perplexed pharmacist, although to explain "sal microesomicum" by quoting as a synonym "salts of urine," is surely "ignotum per ignorantem."

In Part iv. the Chapters xlix. to lxi. include the organic substances employed in pharmacy, classified under the following headings:—"The Cellulose Group;" "Amylaceous and Muclulinae Principles;" "Sugars and Saccharine Substances, and Derivatives of Sugars;" "Aldehyde: its Derivatives and Preparations;" "Products of the Action of Ferments upon Acid Saccharine Fruits;" "Volatile Oils;" "Official Drugs and Products containing Volatile Oil with Soft Resin;" "Resins, Oleoresins, Gum Resins and Balsams;" "Fixed Oils, Fats and Soaps;" "Drugs containing Glucosides, &c.;" "Drugs containing Saponi-

A good deal of space is devoted to a list of the non-official drugs or preparations under each chapter, the name, botanical source, and dose of each being given. These doubtless prove very useful to the student, when in business, for reference, but he could hardly be expected to remember them all. Indeed, this part of the work seems more properly to come under materia medica. If, in a future edition, the space occupied by these non-official drugs could be devoted to giving a fuller account of the conditions under which the active principles exist in each drug, and the action of solvents upon them in the natural state, it would probably be more useful knowledge to the student of pharmacy.

The chapter on volatile oils is scarcely up to date, the known constituents of the more important volatile oils of lemon, bergamot, lavender, cajuput, etc., not being mentioned. The chapters on fixed oils, glucosides, and alkaloids would also be improved by a little more attention in bringing them up to date. The extent of ground covered in the work is, however, so enormous that a little deficiency in the parts which more strictly belong to materia medica may be left out of consideration on account of the great value of the parts that relate to pure pharmacy and dispensing. Like the 'United States Dispensatory,' Remington's 'Pharmacy' is a book for reference, as well as for use in the class, and will be kept on the shelves as a friend by the student long after he has passed all his examinations.

The volume contains so much information that English pharmacists will find it an invaluable addition to the shop library, whilst to pharmaceutical students it can be strongly recommended as treating of pharmaceutical processes and pharmaceutical apparatus more thoroughly than the majority of other similar works.

Books, etc., received.

FRIEDRICH AUGUST FLÜCKIGER.

The death on December 11, at Berne, at the age of 66, of Dr. Friedrich August Flückiger—an Emeritus Professor of the University of Strasburg, and one of the honorary members of the Society—is an event which will produce throughout the entire world, in pharmaceutical circles where science is valued, the deepest regret and the greatest sympathy. Since there is no doubt that at a subsequent period a complete biography of this prominent authority and investigator will be published in some German journal, only a short sketch of his life and partial recognition of his scientific achievements will be attempted on the present occasion.

F. A. Flückiger was born on May 15, 1823, at Langenthal, a small village in the Canton of Berne. The son of a merchant, he received an education partly in his native country, partly in Berlin, at a commercial institute very celebrated at that time, and he was intended for a pharmaceutical career. He passed through the whole pharmaceutical curriculum, having been placed as a pupil, in the year 1847, with an apotheker in Solothurn. He was then engaged for a short time in France, Germany, and Switzerland, as an assistant, concluding his pharmaceutical studies in the year 1851-52 at Heidelberg, where, in the position of chemical assistant to Professor Delfs, he obtained the degree of Doctor of Philosophy by means of a dissertation upon the fluorine compounds of antimony, which was distinguished by the care and precision of the work.

In the following year he worked in Paris with the well-known chemist, Wurtz, and after adding to his knowledge in London, began, in 1853, his career as a practical apotheker and part-proprietor of a pharmacy in the small town of Burgdorf, near Berne. There he prosecuted his occupation until 1890, together with incidental scientific and literary studies, and then took the position of manager of the State pharmacy in the town of Berne, to which place he transferred his residence. He occupied this position—with which several other officials, (for instance, the members of the Sanitary College and the Pharmaceutical Examiners) were connected—and at the same time that of forensic chemist to the Canton of Berne until 1873.

A year after taking this new position in Berne he began to give public lectures on pharmaceutical subjects, especially pharmacognosy, as tutor at the University of Berne, and in 1870 he was elected extraordinary professor in recognition of his academic activity.

In 1873 he accepted the very complimentary invitation to take the professorship of pharmacy and directorship of the pharmaceutical institute at the newly-established University of Strasburg, where he continued for nearly twenty years as an ornament of its mathematical and natural science faculty, and where his death is now lamented as a great loss. With the greatest success and indefatigable loyalty he continued his labours as teacher, investigator, and author until 1892, when, at the age of sixty-four, he resigned, with the object of spending the evening of his life in the undisturbed quiet of literary work in the chief town of his native canton, after having devoted the best years of his life to the academic representation and promotion of his calling.

At the invitation of a friend he visited New York during this year, returning from there with many pleasant and instructive recollections at the commencement of October. Very soon afterwards indications of a complaint, which had no doubt long been latent, manifested themselves and in a very short time terminated his life.

Flückiger's scientific achievements and merits cannot of course be sufficiently acknowledged in a short sketch of his life, but only mentioned in a cursory manner. Indefatigable industry in scientific investigations was a characteristic of his work, assisted as it was by remarkable powers of memory, and an astonishing acquaintance with all departments of literature relating to pharmaceutical and natural science. This is the key to an almost astonishing many-sidedness which enabled him without the least danger of superficiality to carry out important work in all departments of his calling, and in almost equal degree to cultivate pharmacognosy, pharmaceutical chemistry, and the history of chemistry and of drugs, with such success that, independently of his larger writings, upwards of 300 memoirs have been contributed by him to pharmaceutical literature on those subjects.

For a powerful stimulus in promoting his scientific calling he was, no doubt, indebted to his intimate participation in the construction of the first Pharmacopoea Helvetica while residing at Burgdorf. This he had to carry out as President of the Swiss Apotheker-Verein from 1857 to 1866. He was also engaged as chief editor of the second edition of the Pharmacopoea Helvetica, 1872. The preliminary work, experiments, observations, and literary studies necessary for this purpose may be regarded as the basis of his "Lehrbuch der Pharmakognosie des Pflanzenreiches," carried out in Berne, the first edition of which was published in 1867 by Gaertner, at Berlin, and acquired for him at once a universal reputation and well-earned recognition. That work, the second and third editions of which appeared in 1883 and 1891, founded a new epoch in the science and study of pharmacognosy, one of the most eminent representatives of which Flückiger was generally acknowledged to be.

Of still greater interest to all English-speaking pharmacists was "Pharmacographia," published in 1875 conjointly with Daniel Hanbury. In conjunction with that distinguished representative of English pharmacy, Flückiger continued for many years a joint work, which led to the production of a book which is not only generally valued throughout England and America, but was also of importance in regard to all the subsequent publications by Flückiger upon the subject of pharmacognosy. After the death of Hanbury in 1878, the second edition, revised by Flückiger, was published by Macmillan. During the
same year appeared the first edition of his ‘Pharmaceutical Chemistry,’ which treated in a masterly monographic manner of the more important pharmaceutical chemicals, and contained an abundance of original observations by himself. The second edition of this work was published in 1888. As supplementary to his ‘Leybucb der Pharmakognosie,’ Flückiger published in 1873 the ‘Grundlagen der pharmakognosischen Waarenkunde,’ of which a second edition appeared in which Professor Tschirch assisted, and where the anatomical botanical relations indispensable to the study of pharmacognosy were treated of. Since the relatively large extent of Flückiger’s ‘Pharmakognosie’ rendered that work less suitable for the use of students, he reproduced its quintessence in a more compact form as a small handbook, the ‘Grundriss der Pharmakognosie,’ which was intended for use by students attending lectures. This book, which soon became popular throughout German-speaking countries, was published in 1884, and in 1894 a second edition appeared, not long before the death of the author.

One of the last literary productions of this pharmaceutical author was the work entitled, ‘Reactions,’ published in 1892, in which the chief chemical reactions of the more important organic substances used in medicine and pharmacy are described, and an inconceivably large number of original observations by the author are recorded. This was in part a fruit of his labours as member of the Pharmacopœia Committee of the German Empire. Passing over Flückiger’s historical writings, it may be mentioned that he proved himself a master of style in numerous essays, accounts of travels, and other literary productions. His way of writing made all his productions in the highest degree attractive.

In concluding this brief notice, it may be said that Flückiger gave evidence of a combination of unusual natural faculties, with a great store of carefully acquired knowledge and untiring industry, giving rise to unique literary productions. No one can be compared with him or anyone placed before him as having contributed so largely to scientific pharmacy. Switzerland, his native land, will long continue to include him among her most eminent scientific men. Honour to his memory!

EDWARD SCHAER.

Notice has also been received of the death of the following:—

On November 10, Frederick Allwork, Chemist and Druggist, London. (Aged 69.)

On November 27, John Gill Blackburn, Chemist and Druggist, Leeds. (Aged 57.)

On November 28, John Roddam Sayer, Chemist and Druggist, Sunderland. (Aged 56.)

On November 28, Robert Gadd, Chemist and Druggist, Vauxhall. (Aged 50.) Mr. Gadd’s membership with the Society dated from 1869.

On November 30, W. F. E. Horrell, Pharmaceutical Chemist, Exeter. (Aged 25.) Mr. Horrell was only elected a member of the Society in June last, having passed his Major examination in October, 1893.

On November 30, Alfred Richardson, Chemist and Druggist, Manchester. (Aged 42.)

On December 5, Thomas Womack, Chemist and Druggist, Stratford-on-Avon. (Aged 47.)

On December 9, James Stewart, Chemist and Druggist, London. (Aged 51.)

On December 10, Thomas B. Spence, Chemist and Druggist, Edinburgh. (Aged 76.)

On December 10, Edmund Staples, Chemist and Druggist, Wilton. (Aged 83.)

On December 11, Thomas H. Tees, Chemist and Druggist, Lelystad. (Aged 69.)

On December 14, John B. Robson, Chemist and Druggist, Filey. (Aged 69.)

Notes and Queries.

NEW PHOTOGRAPHIC REDUCER.

[796.] A correspondent of the Amateur Photographer recommends a new combination for reducing overexposed prints. A cold saturated solution of sodium hyposulphite (about 20 per cent.) is diluted with four times its volume of water. To 100 C.c. of this is added 1 C.c. of a 10 per cent. solution of uranium nitrate. The prints are immersed in the solution for a few minutes until sufficiently reduced, then washed, and fixed with the following solution:—lead nitrate, 10 parts; (gramme) and sodium hyposulphite, 200 parts, are dissolved in distilled water, 1000, whilst just before using, 50 C.c. of a 1 per cent. of gold chloride solution is added (Nouveau Remède).

SOLUBILITY OF COCAINE HYDROCHLORATE IN VASELIN.

[854.] In reference to the dispensing query on page 371, several correspondents recommend W. F. G. to rub up or dissolve the hydrochlorate of cocaine in a minimum quantity of water, and then thoroughly incorporate with the vaselin. Such an ointment is probably more efficacious than a solution of the alkaloid itself in a fatty expipient, but in either case the addition of oleic acid would be undesirable, remarks one correspondent. Another suggests that a better preparation would be made by dissolving the alkaloid itself in oleic acid and mixing this with the vaselin, though this course would not be justifiable when the hydrochlorate of the alkaloid is prescribed. It may be pointed out, however, that the evident desire of W. F. G. was to ascertain how the salt might be incorporated in the ointment in a state of solution. It is slightly soluble in melted vaselin, but only to the extent of about half what is ordered in the prescription. The alkaloid itself is more soluble, but its use would not be justified, and whether the hydrochlorate should be partially dissolved or not would depend to some extent on what was known regarding the prescriber’s intentions.

Patent Office Business.

APPLICATIONS FOR PATENTS.

No. 21,589.—Thomas Tildesley, 1, Furnival Street, Holborn—Improvements relating to pills. November 8, 1894.

No. 22,332.—Thomas Jardine, 58, Chancery Lane, W.C.—An emulsion or specific for human use possessing nourishing and curative properties. November 19, 1894.
Correspondence.

BEESWAX, BEREACHED AND UNBLEACHED.

Sir,—The contamination of English beeswax with parafin and similar bodies, such as ozokerit, owing to the artificial "comb foundations" to assist bees in the more rapid production of honey, is becoming so general that it seems necessary to call the attention of pharmacists, and through them of producers of beeswax, to the subject. Although comparatively little of the wax employed for general economic purposes is of British production, the bulk of that employed in pharmacy is collected in this country. The presence in beeswax of parafin, ozokerit and other bodies unacted upon by sulphuric acid, may be readily proved by the application of the United States Pharmacopoeia test for that purpose, coupled with the neutralisation and saponification equivalents. Of three samples of English beeswax recently obtained from districts wide apart only one was found to be free from parafin, while samples of foreign beeswax, which reached the port of London from Jamaica and Madagascar, as well also as East Indian bleached wax, produced undoubtedly without any artificial assistance to the bees, were found quite free from this contamination. The melting point of various waxes may vary within slight limits of that prescribed by the British Pharmacopoeia, the other tests being readily complied with, but a wax containing parafin and ozokerit of suitable melting points may also answer the same requirements. It seems desirable, therefore, to impress on bee-keepers the necessity of using pure beeswax "comb foundations" only, and on pharmacists the advisability of carrying the testing of beeswax somewhat further than that prescribed in the British Pharmacopoeia. Southwark, London. JOHN G. MEY.

EUCALYPTUS OIL.

Sir,—After the Evening Meeting of the Pharmaceutical Society, on December 12, I elicited from Mr. Payes, of Adelaide, that competent medical authorities in Australia had been supplied by him with pure constituents of eucalyptus oil, solid and liquid, and that the pharmacological and therapeutic action of the substances had been determined. He promised to urge the publication of the results through the usual medical channels. J. ONT AYFIELD.

THE APPOINTMENT OF EXAMINERS.

Sir,—Regret has often been expressed by those of us who wish well to our Society at the lack of interest that is taken in the election of Councillors. The recent "departure in inaugurating a new system of examination" would seem just such a topic as would have evoked a good deal of interest in the election, had it been fairly put before the electors. Where organic changes of this character are made without a chance being given to the members of the Society to express an opinion upon the matter, one cannot wonder at the apathy of many as to who shall represent us. Personally, I yield to none in my esteem for Professor Green, and I am therefore very sorry that our Council has placed him in such an invidious position. The examination of candidates for qualification to practise pharmacy is the most important function delegated to the Society by Parliament. Such being the case it is of paramount importance that the examination be conducted in such a manner as to be altogether above suspicion, even in the eyes of those who are but too ready to find fault with anything the Society may do. There is an impression abroad among candidates from other schools of pharmacy that in some way students from Bloomsbury Square are favoured—an unfounded impression I verily believe—but, nevertheless, it exists, and should have been taken into account. Much may be said, and was said, at the Council meeting of the advantages of allowing a professor some share in the examination of his own pupils. But very little was said of the manifest inadmissibility of allowing the professor of one school to share in the examination of students from other schools—schools, moreover, considering themselves rivals of the institution to which such examining professor is attached. At a time when we had thought there were signs of consolidation among the members of our craft, a measure that will tend to alienate from the Society the large number of men entering business otherwise than through the School of Pharmacy at Bloomsbury Square is much to be deplored. Especially so, after the determined opposition which the proprietor of another school of pharmacy justly encountered a few years since in his attempt to obtain a seat upon the Council. Under the altered circumstances of the case he may calculate upon a much greater chance of success in any future candidature. From a sense of fair play (I trust not a mistaken one) Mr. Wills may count upon my vote, if I still retain one, in future election if he should seek it. The Vice-President ventured the hope that the "impression would not get abroad that they were aspiring interested men as examiners." Why the fear of such an impression unless the Vice-President, who seconded the motion, were conscious of a course of action being entered upon such as would tend to spread an impression of the kind?

Bristol.

E. F. YOUNG, M.P.S.

* * 

Our correspondent is mistaken in thinking that the appointment of professorial examiners is an "organic change," or that it has not been fairly put before the electors, as it was one of the subjects under discussion at the latest alteration of the bye-laws (see reports in Pharmaceutical Journal). In reference to the hope (not the fear) expressed by the Vice-President, we may suggest that it was instigated by the belief that any such impression as that referred to would be unfounded, and we fail to recognise the propriety of regulating the examinations to satisfy unfounded impressions.—[Ed. Pharm. Journ.]

Diary of the Week.

THURSDAY, DECEMBER 27.

Royal Institution of Great Britain, at 5 p.m. "The Manufacture of an Electric Current" (Lecture I.), by Professor J. A. Fleming.

FRIDAY, DECEMBER 28.

Aberdeen Chemists' and Druggists' Assistants' and Apprentices' Association, at 9.30 p.m. Social Meeting.

SATURDAY, DECEMBER 29.

Royal Institution of Great Britain, at 3 p.m. "The Electric Current working as a Chemist" (Lecture II.), by Professor J. A. Fleming.

Communications, Letters, etc., received from Messrs. Black, Cracknell, Elborne, Hill, Holloway, Long, Mathews, Parker, Rideal, Schuer.
"THE MONTH."

F. Gaud has obtained lactic acid and ethylideno-lactic acid by heating propionic acid with Fehling's solution for a prolonged period, at 240° C. The reaction is probably represented by one of the following equations:—

\[ 2\left(\text{C}_2\text{H}_5\text{O}_2\text{C}_6\text{H}_5\right) + 2\text{H}_2\text{O} \rightarrow 2\text{C}_2\text{H}_5\text{O}_2\text{C}_6\text{H}_5 + \text{C}_6\text{H}_5\text{O}_2 \]

or

\[ 2\left(\text{C}_2\text{H}_5\text{O}_2\text{C}_6\text{H}_5\right) + 2\text{H}_2\text{O} \rightarrow 2\text{C}_2\text{H}_5\text{O}_2\text{C}_6\text{H}_5 + \text{C}_6\text{H}_5\text{O}_2 \]

He also finds that propionate of copper, heated at 180°-200° with an excess of water, for fifty or sixty hours, is decomposed into metallic copper, cuprous oxide, together with propionic and lactic acids (Comp. rend., ix., 960).

E. Bossi has proved that stizoboscococcus bacillaris, Nagell, and other Algae will live and exercise their reproductive power in nutritive solutions containing arsenic acid, and even assimilate the acid. Further, the phosphates in nutrient solutions may be replaced by arseniates, and the Algae will yet continue to thrive (Comp. rend., xxiv., 929).

Ozone is shown by Malbert to be solvable in water to the extent of 3-4 Mgm. per litre at 0°C., 25-9 Mgm. at 15°, 13-0 Mgm. at 27°, and 0-6 Mgm. at 55°. He suggests therefore that this property of ozone may be utilised to sterilise water in certain circumstances, and that ozonised water may serve as an antiseptic and disinfectant in hospitals (Comp. rend., x., 961).

W. Spring describes a form of black mercury sulphide obtained by subliming the ordinary black sulphide in an atmosphere of nitrogen or carbon dioxide. Its density is 8-0938 at 17° C., that of the ordinary black sulphide being 7-9249, and that of the red, 8-1587. M. Spring points out that the lighter of two allotropic modifications of a body may usually be converted into the denser form by compression, although sometimes the change is possible only above a certain "critical" temperature. To convert the ordinary sulphide into the red variety by this method would require the at present unobtainable pressure of 35,000 atmospheres, but the new variety, which has a density lying between the others, can be so converted by a pressure of 2500 atmospheres. It is possible that these observations may have some practical bearing on the manufacture of vermilion (Bull. de l'Academie Royale des Sciences, etc., de Belgique, xxviii., pp. 238 to 257).

E. Maumenez purifies alcohol, sugars, and other organic bodies by the action of potassium permanganate. If a litre of impure alcohol be agitated with 2 C.c. or 3 C.c. of aqueous permanganate solution, oxides of manganese are precipitated, the impurities are oxidised, and any bad taste disappears, and after allowing a clear liquid may be decanted. The same process is recommended for purifying red and white wines, which are said to lose but little of their colour or bouquet, as well as for refining sugars and improving potable waters (Comp. rend., x., 1014).

Reduction of Alumina.

H. Moissan has investigated the reduction of alumina in the electric furnace, and finds that when-the oxide is in the liquid state it is not reduced by carbon, but when the vapours of both alumina and carbon are heated to an exceedingly elevated temperature, reduction of the oxide to metallic aluminium takes place (Comp. rend., ix., 938).

The number 210, obtained by Dumas in 1859, and generally accepted as the atomic weight of bismuth, has been disputed by Marignac, who in 1883 gave the atomic weight as 208-16, and, more recently, by Olsenn, who obtained 208-9. R. Schneider gives as the result of a re-determination of this factor, 208-05, a number confirming the determination which he published forty-three years ago, and closely agreeing with that of Marignac (Journal für praktische Chemie, N.S., I, No. 9).

Synthetic Guaiacol, and other cresolates is frequently very impure, and sometimes contains less than 50 per cent. of active substance. Béhal and Choisy in 1893 succeeded in making guaiacol synthetically in a nearly pure condition (see Pharm. Journ. [3], xxiv., 750), and since that date, by recrystallisation, an absolutely pure guaiacol has been prepared commercially. The pure synthetic product is likely to be used in preference to the natural preparation as a prophylactic in cases of tuberculosis. Professor Marfori has recently made an exhaustive comparison between the crystallised synthetic product and the purified guaiacol from beechwood. He finds them to be chemically and therapeutically identical, and advocates the use of the synthetic product in preference to the commercial variety from cresote, since it is of guaranteed purity (Ann. di Chim. e Pharmac., 1894, 284).

Myrhorin.

Guignard has already shown that myrroin (or at least a ferment decomposing potassium myronate) occurs not only in Orcusifera, but also in Limanthophora, Tropeaolus, Reseda, and Papaveraceae, and is found in the root, stem, leaf, and seed; the wing of Lunaria seed contains it in abundance. The ferment, he finds, is weakened in action at a temperature of about 30° C., and is destroyed at 55° C. Its action is not entirely prevented by 1 per cent. of tannin, 5 per cent. of chloral, or 8 per cent. of borax or alum. On the other hand, its activity appears to be checked by 15 per cent. of salicylic acid (Journal de Bot., 1894, 418).

Persulphates as Disinfectants.

L. Wacker finds that ammonium persulphate in 1 to 2 per cent. solution has a very powerful disinfecting action, killing cholera and other germs in a few minutes. It has the formula (NH₄)₂S₂O₃, and is prepared like the potassium salt, by electrolysis a solution of ammonium sulphate acidulated with dilute sulphuric acid. The salt formed in this way is purified by cooling in a solution saturated at the ordinary temperature. It appears that a solution of this salt has scarcely any action upon the higher animals, and can therefore be used as a preservative for fish or meat. It is also a deodorant, and can be used for removing the objectionable smell from faeces (Chem. Centr., 1894, 873).
P. Adam has investigated the behaviour of antimony oxide towards organic acids containing an alcoholic hydroxyl group, and has succeeded in obtaining compounds analogous to tartar emetic with the salts of both lactic and malic acids. His results confirm Jungfleisch's suggestion that the oxide of antimony acts as an acid and not as a basic substance, and that therefore the emetics should be classified as eaters, or ethereal salts, of the corresponding compounds, with which they are derived.

In preparing these new emetics, the author boils a solution of the salt of one of these hydroxy-acids with the oxide of antimony. The free acid usually yields no such product. E. Maumoné has partly confirmed these views by careful analysis of tartar emetic and its analogues, and he shows that the formula of these compounds must be of a more complex character than that usually accepted (Compt. rend., cxviii., 1418).

Prof. J. Richards states that the best results in soldering aluminium have been obtained with an alloy of zinc, tin, aluminium, and phosphorus. The solder can be used with the blow-pipe or a soldering iron, a little silver being added in the former case to make it harder and give it a better colour. No flux of any description is required in using it (Aluminium World and Journ. Am. Chem. Soc., xvi., 881).

M. Schlagdenhauffen finds that phosphates and alkaline hypophosphites frequently contain arsenic, although in very small proportion, and he urges therefore that only such preparations should be employed in medicine as yield negative results when tested in Marsh's apparatus (Bull. com., 1894, 466).

Wolfenstine has observed that hydrogen peroxide is much more stable than is commonly supposed. A solution containing 4.5 per cent. can be evaporated on a sand-bath until the percentage rises to 66.6; the loss is considerable when the strength is over 15 per cent., but is due to vaporisation, not to decomposition. Such evaporation, however, can only be successfully accomplished if the solution be free from every trace of alkali, compounds of heavy metals, and solid bodies of any kind, even if chemically indifferent. By concentrating a solution—by shaking with ether, evaporating the etherial liquid, and fractionally distilling in a vacuum (68 millimetres) at 70°-80° C.—a product was obtained containing 99.1 per cent. of hydrogen peroxide (Ber. d. ph. Ges., iv., 247).

W. D. Bigelow and C. C. Hamilton find that the presence of alum in bread interferes materially with gastric digestion, but the aluminium seems to be precipitated by the alkali of the pancreatic fluid, so that the latter effects a portion of the digestion which should be effected by the peptic. The influence of aluminium hydroxide is about the same as that of alum, but aluminium phosphate acts quite differently, 10 to 12 per cent. of the aluminoids that are digestible in the presence of alum or aluminium hydroxide being apparently insoluble in the presence of an equivalent amount of the phosphate (Journ. Am. Chem. Soc., xvi., 587).

Pure Ether. H. Thorntn finds it impossible to obtain ether that will not restore the colour to fuchsin decolorised by sulphurous acid, and show an alkaline reaction with moistened red litmus paper. He comes to the conclusion that these are properties of chemically pure ether, and his opinion is confirmed by the fact that ether obtained in Fiset's laboratory by freezing behaves in a similar manner. The production of bodies thus formed by the action of air on pure ether, such as acetic acid, acetaldehyde, peroxide of hydrogen, etc., is not prevented by the addition of two per cent. of alcohol (Ber. d. ph. Ges., iv., 239).

Disinfection of copper sulphate is the best disinfectant for copper sulphate, fumaric acid, ceric acid, osmium, satisfactory results being obtained in twenty-four hours with 7 Gm. to 8 Gm. of the salt per 1000 C.c. of matter disinfected. For typhoid and cholera dejecta 6 Gm. and 4 Gm. respectively, per 1000 C.c. sufficed, the comma bacillus disappearing in a few hours. The absence of the fluidity of the matter to be disinfected, the sooner is the result attained, whilst a smaller proportion of disinfectant is required in summer than in winter, other things being equal. The presence of alkalies tends to check the action of both copper sulphate and chlorinated lime. For normal excreta mixed with urine it is recommended to employ 6 Gm. of sulphate per 1000 C.c., to effect disinfection within twenty-four hours; in typhoid cases 8 Gm. per 1000 C.c. should be used; whilst for cholera dejecta 3.5 Gm. per 1000 C.c. will suffice, twelve hours only being required in the last two cases (Compt. rend., cxix., 866).

B. Bertrand and A. Maillere find that pectate (see Ph. J. [3], xxiii., 972) alone cannot coagulate pectin, but only effects that transformation in the presence of a soluble salt of calcium, barium, or strontium. The precipitate formed has been generally understood to be pectic acid, but it is now shown to be a pectate of an alkaline earth (Compt. rend., cxix., 1012).

Methylalcohol in Conline. Wolfenstine has examined commercial "pure water-white conline," and found it to contain another alkaloid which was separated by crystallisation of the tartrate, and proved to be methylalcohol. It boiled at 173°-174° C., and possessed a specific rotatory power of +81°33 (Ber. d. ph. Ges., iv., 242).

Dr. T. G. Wormley has investigated the limits of applicability of some of the tests for quinine. In the thalassoquin test, a saturated aqueous solution of bromine (about 3 per cent. by weight) gave a green coloration with 1-20,000th quinine solution, but when the reagent was diluted to half strength, a well-marked green colour was obtained. When chlorate was used, however, no green coloration could be obtained, even though the strength of the reagent was varied. With stronger solutions of quinine, however, Wormley finds that when an aqueous solution of chlorate is employed, a positive reaction manifests itself through a greater range than when the more sensitive bromine is employed, the result being less readily affected by excess or deficiency of the reagent. With the harmoniatic test, no adjustment of the reagents was required to obtain satisfactory results with the residue from a drop of
a 1–1000th quinoline solution, if simply moistened with acetic acid (30 vols. strong acetic acid to 10 vols. strong alcohol, and 1 vol. 1:10 sulphuric acid), and then with a minute drop of iodine solution (iodine 1 part, alcohol 2 parts, by weight). Fluorescence was well marked in a 1–1000,000th solution of quinine acid sulphate (normal) on the addition of a drop of dilute sulphuric acid, though only faint previously. Under certain conditions, however, as with Kerne’s fluorescence, a marked fluorescence is indicated in solutions of the alkaloids under a dilution of two million times. Chlorides, bromides, iodides, and their free acids, prevent fluorescence, and Sestini and Campani noted that it may be concealed by the presence of phencsceint, which may also cause variations in the thalassiquin test. The bitter taste of the acid sulphate is said to be perceptible in a single drop of a 1–20,000th solution, but not in a 1–50,000th solution (Am. Journ. Pharm., lv, 561).

Calcium. The production of acetylene from calcium carbide, a by-product in the electrolytic reduction of aluminium and other refractory ores, is said in the current number of Industries and Iron to be likely to become a factor in gas manufacture. Acetylene has about the same illuminating power as the oil gas now so largely used in enriching coal gas, but the dangerously explosive nature of a mixture of acetylene and air may possibly preclude its use in large quantity as an enricher.

Professor Victor Meyer describes the production of the compounds C₂Cl₄ and C₃Cl₆ at temperatures as low as 20° to 40° C., during the preparation of carbon tetrachloride by the chlorination of carbon disulphide. It has long been known that carbon tetrachloride is partly decomposed at a red heat with liberation of chlorine and formation of the chlorides C₂Cl₃ and C₃Cl₅, but it is now evident that the decomposition occurs, more or less, at far lower temperatures. In the preparation of the tetrachloride at the works of Müller and Dubois, near Mannheim, by the above-named process, the product is distilled from the sulphur dichloride, which is produced with it, and is then re-distilled. During the latter operation, an oily liquid, boiling at a higher temperature, is obtained. After the dichloride has been obtained, and this has been shown by Victor Meyer to contain the liquid chlorides C₂Cl₄ and C₃Cl₆, and the solid chlorides C₂Cl₃ (perchlor-ethane). Professor Meyer considers that the two latter compounds are produced according to the equations:—

\[ 208 + 8Cl = C₂Cl₄ + 2C₃Cl₆ \]

(\[ 208 + 10Cl = C₃Cl₆ + 2C₃Cl₆ \]

\[ (Berichte, 1894, p. 3180). \]

J. Curtin finds that when stannous chloride is used as a test for arsenic, the utmost limit of reaction, for practical purposes, is reached when 0.03 Mgm. of arsenic is present per 1 C.c. of solution, and that the method in which metallic tin and heat are employed is to be preferred where antimony and bismuth are absent. Both with the U.S.P. solution (without the use of metallic tin), and with that of the German Pharmacopoeia, the greatest intensity of colour, after an hour’s reaction, occurred when 0.001 C.c. of the arsenical solution was mixed with 2.5 C.c. of the reagent. Though metallic tin accelerates and intensifies the reduction of arsenic, it also reduces bismuth or antimony if present, and distinction between the precipitates might then be difficult. In several instances in the U.S.P., where this test is intended to detect the presence of arsenic as an impurity—as in the case of bismuth and antimony salts—tin foil has, by an error in transcribing, been directed to be added (Journ. Am. Chem. Soc., xvi, 580).

Cusco! Phosphate. According to M. Ballard a compound can be prepared containing 92.26 per cent. of gusiacol and 7.74 per cent. of phosphorus. The resulting product is a white crystalline powder, non-caustic, melting at 77°, very soluble in alcohol, ether, or chloroform, but less soluble in water, fatty substances, or benzoin, and still less in glycerin. The compound is said to be well tolerated when administered, but its therapeutic action has not yet been sufficiently studied (Bull. com., Nov., 519).

Protids of the Kidney. Prof. T. B. Osborne has identified the kidney bean (Phaseolus vulgaris) with two distinct protids—"phasesol" and "phasesin"—which have the properties of globulins. The two globulins are characterised by great solubility in very dilute saline solutions, and by yielding precipitates with acids, which are soluble in sodium chloride solution. Phasesol probably forms about 26 per cent. of the seed, and is the protid described by Rittthausen in 1884. Phasesin is much more soluble, and remains in solution after the phasesol has separated. It is slowly coagulated by heat at temperatures varying with the amount of salts present and the rapidity of heating. Acids precipitate it, and by prolonged dialysis insoluble or albuminate modifications are yielded. Phasesol possesses properties more nearly resembling those of a globulin than of any other recognised class of protids. In addition to the two globulins an extremely small amount of proteose was found (Journ. Am. Chem. Soc., xvi, 633, 703, and 787).

Protids of Cotton Seed. Prof. R. Osborne and Voorhees show that the water-soluble matter of cotton seed consists almost wholly of proteose, and does not exceed 0.75 per cent. of the oil-free meal (two per cent. total N.). A salt-soluble globulin, "acelin", occurs to the extent of 15.83 per cent., containing 42.3 per cent. of the total nitrogen. Other proteid matter was alkali-soluble but salt-insoluble (44.3 per cent. total N.), or insoluble both in salt and alkali (11.4 per cent. total N.) (Journ. Am. Chem. Soc., xvi, 778).

Determination of Starch. W. E. Stone compares the methods in use for the determination of starch—including inversion with hydrochloric, nitric, and salicylic acids, and precipitation by barium hydroxide—and finds that they will all yield satisfactory results when dealing with starch alone. Such bodies as the pentosans, however, respond to the same reactions as starch, this being proved conclusively in the case of "xylan," the pentose most characteristic of feeding stuffs. The application of diastase or malt infusion to the starch-containing material seems to avoid this difficulty, and, though there are minute objections to dialyzed sets, they are more than compensated by the greater accuracy secured (Journ. Am. Chem. Soc., xvi, 796).
Rubus Villousus.

H. Harms has studied the glucooidal principle and the tannin found in the bark of this plant. The former was found to correspond with the "villoisin" previously obtained from the bark by Krauss (Am. Journ. Pharm., 1899-90), and is probably one of the saponins. It yielded viscolic acid as a decomposition product. Tannin was present in the dried bark to the extent of from 12 to 19 per cent., in different samples. It is described as dark brown in colour, faintly odorous in water or alkaline solutions, sparingly soluble in ether or acetic ether, and insoluble in acetone or benzol (Am. Journ. Pharm., xli, 590).

Asbestos Filter. A novel and ingenious filter has been presented to the Société de pharmacie du Sud-Ouest, and is described in the Society's Bulletin for November as free from many of the disadvantages of filters made of paper, flannel, etc. It consists of a covered tinned copper cylinder, below which is fixed an inverted cone of very fine wire gauze, and the whole is supported on an ordinary funnel stand. The liquid to be filtered has a small quantity of powdered asbestos suspended in it, and is then poured into the cylinder. The asbestos forms a filtering layer upon the wire gauze, and the liquid passes through perfectly clear. The wire gauze is afterwards washed with water, and is then ready for further use. The apparatus is said to have been used with advantage to filter syrups, decoctions, infusions, distilled waters, medicated wines, etc., economy being effected both in time and material. It is manufactured in all sizes by the Comptoir Français des Filères Asbestos, 138, Avenue de Paris, plaine St. Denis (Seine).

Origin of Vascular Plants. According to Professor D. H. Campbell, it is generally admitted that the origin of the vascular plants is to be sought among the less specialised Bryophytes, which in turn were derived from algal ancestors. In the evolution of the sporophyte it gradually passed from a condition where its whole substance was devoted to spore formation, to that where a portion was resorbed by the fungus to the vegetative life of the sporophyte. The latter, by the development of special organs—roots and leaves—became free from the gametophyte upon which it had lived as a parasite, the genus Anthoceros being the nearest to realising this condition among living Bryophytes. From such a condition several lines of development have probably proceeded, resulting in the different groups of Pteridophytes, which in turn may have independently given rise to seed-bearing plants (Science Progress, Dec., 278).

C. H. La Wall directs attention to the extreme importance of carefully fully regulating the temperature in making cinchona ointment. He finds, after a long series of experiments, that lard oil is the best vehicle to employ, and recommends the following process:—Heat the oil to 100° C., and then add the nitric acid without stirring. Then heat again in a vessel capable of holding six times the quantity of the ointment to be made, and until effervescence ceases. To the mixture cooled to 40° C. the mercuric nitrate is then added in solution, the temperature being gradually allowed to rise until 60° C. is reached. This latter temperature is main-
tained until no more gas is evolved, and the product is then agitated until cold. When prepared in this way, the ointment is in every way satisfactory, and keeps well (Amer. Journ. Pharm., 1894, 925).

California Winemakers Which appear to prove that California dry wines are fully equal to the European wines, and that the red wines are in every respect superior to young French clarettes. The sweet wines are not plastered, and are said to be preferred by persons whose preference is for wines containing the same amount of alcohol and extractive (Journ. Am. Chem. Soc., xvi, 597).

Dr. Julien, according to the Repertoire de Pharmacie, mixes 2-5 per cent. of calomel and "traume-lioine," which consists of a 10 per cent. solution of gutta percha in chloroform, and this mixture he uses as a paint in skin diseases. He applies it to the part affected with a brush. The mercury is rapidly absorbed, as shown by its early presence in the urine, and has been found beneficial in all cases of skin diseases, a daily dose not exceeding 0.1 grm.

New Ameroplast. (Capsella bursa-pastoris) is recommended as a substitute for Hydrastis canadensis as a hemostatic, in doses of 0.1 to 0.15 grms thrice daily. The active principle is said to be bursinic acid, which can also be administered as a sodium or iron salt (Ann. di. Chim. e Pharm. 1894, 303). TolouIn in its original form has already been given in the Journal (ante, p. 433) and is as follows:—Absolute alcohol, 60 C. c.; toluol, 36 C. c.; ferric chloride (solution), 4 C. c. To render its application less painful, however, Löfler adds menthol, the formula then being:—Menthol, 10 Grm.; toluol, q. s. to make 36 C. c.; absolute alcohol, 60 C. c.; ferric chloride, 4 C. c. In certain cases, also, where sulphur compounds, occurring on the tongue and false membrane decompose the ferric chloride, a further modification is adopted, thus:—Menthol, 10 Grm.; toluol, q. s. to make 36 C. c.; absolute alcohol, 61-62 C. c.; creolin or metacresol, 2-3 C. c. In cases of gumorrhoea to be given to the original mixture. It should be applied every three hours until the temperature becomes normal and the general condition of the patient is satisfactory, after which three applications daily will be found sufficient. The development of the diphtheria bacillus is said to be checked by the remedy, whilst fully developed forms are destroyed in a few seconds. The mixture may be kept in stoppered bottles for several months without change, and, though after a time aromatic ethers are developed, the activity of the preparation is not in any degree affected (Deutsche Med. Wochen, through L'union pharm., xxxv, 538).

P. Carles classifies syrups into two classes: one those which remain practically unaltered, those which ferment, and those which tend to crystallise, the last being reputed to be subsequently more liable to change in consequence of loss of sugar. It is pointed out, however, that crystallisation only occurs when, at the prevailing temperature, the water is supersaturated with sugar. If the supersaturation is great and the temperature sufficient, crystallisation takes place uniformly over the whole of the inner surface of the containing vessel,
whilst if the supersaturation is not so great, and
the temperature moderate, the crystals form upon the
coldest parts of the bottle only. It may be
taken for granted that in full bottles the syrup is
always saturated at the temperature for the time
being, except when the crystals are confined to
the bottom of the bottle. In the latter case a
syrup remaining saturated throughout the winter
would be under-saturated if kept until the follow-
ing summer, and on the bottle being inverted the
formation of streaks in the liquid would prove
that there had been layers of different densities.
If this condition existed in the case of syrups
requiring the full complement of sugar for their
preservation, it would be to see that crystallisation
would naturally be followed by fermentation.

Adulteration

A. Kremel shows that it is pos-
sible to produce, by mixing Japan
wax, stearic acid, and ceresin in
suitable proportions, a compound
closely resembling genuine beeswax in appearance,
possessing the same melting point and refracting
index, yielding the same figures by Hübli’s saponi-
fication process, and differing only in having a lower specific gravity. He recommends it in all cases in
which the specific gravity should be taken and qualitative
tests applied for stearic acid, resin, and Japan wax
(Pharm. Post., xxvii, 465).

Aristol for

The application of aristol in cases
Burts.

Serviceable by several observers on
account of its anesthetic action. Professor Haas
states that in addition to its favourable influence
in relieving the pain, it has powerful antiseptic
properties (Morph., July, 1894). The affected
parts are first to be washed with a two per cent. solu-
tion of boric acid, the vesicles opened, and the burned
areas covered with aristol gauze, over which steril-
lised cotton, gutta-percha, and a bandage are
applied. After the secretion has diminished, aristol
may be insufflated in substance or applied in the
form of a ten per cent. ointment.

Scopolamine.

A long paper is published in the
Archiv. der Pharm. by Professor E.
Schmidt, in which he supports his former statement
that the base occurring in the roots of Scopolia
atro-
poses, the seeds of Hyoscyamus niger, Datura stra-
tagonis, and the leaves of Duboisia myoporoides, as
well as the roots of Atropa belladonna, and having a
composition corresponding to the formula
C₂₃H₃₈NO₅, is in all essential particulars identical
with Ladenburg’s hyoscyine, and that the base which
Ladenburg isolated from henbane seed under that
name, together with hyoscyamine and atropine, is
not an isomer of atropine but is scopolamine. That
view is also held by Dr. O. Hesse, who has shown
that the pseudotropine described by Ladenburg as
a product of hyoscyine has not the formula C₂₃H₃₈NO₅,
but that of scopoline, C₂₃H₃₆NO₅, as ascertained by
Schmidt, and that the composition of the base,
named hyoscyine, from which it is derived, should be
represented by the formula C₂₃H₃₈NO₅ instead of
C₂₃H₃₆NO₅. Schmidt does not dispute the possibility
of a hyoscyine base existing isomeric with atropine and
hyoscyamine, since there are dubsia leaves,
indistinguishable, which contain hyos-
cyamine, and others which contain scopoline, while E. Merck has recently obtained from them
another base, which he has named pseudohyscy-
cyamine. Schmidt, however, has not obtained hyos-
cine having the composition C₂₃H₃₈NO₅, and all the
samples of commercial hyoscyine, even that bearing
Ladenburg’s name, consist essentially of isopel-
mine. He objects, however, to call this base
hyoscyine according to Hesse’s suggestion, since he
was the first to show that it is not, as previously
assumed, an isomer of hyoscyamine, pseudohy-
cyamine, and atropine, but that it has the formula
C₂₃H₃₆NO₅ and is metameric with cocaine.

Dr. C. Bechert has ascertained that
dulcin dissolves in 237 parts of castor
oil, communicating to it an agreeable
sweet taste. Cod-liver oil dissolves
rather less (54) and some time elapses before the
sweet taste of the substance becomes sensible. The
presence of free fat acid in oil appears to facilitate the
solubility of dulcin very considerably (Apotheker
Zeitung, ix, 351).

In a lecture delivered before the
Antidotes
Medical Association in Halle,
and
Antitoxins.
Professor Harnack dealt with Beh-
ring’s statement that anti-diph-
theritiseum is the first-curative product of the kind
which is harmless, all others being poisonous them-
selves. In reference to this proposition he holds that
anti-diphtheritiseum must be regarded as an anti-
dote, and consequently analogous to other substances
which act as antidotes. These he divides into two
classes, chemical and physiological, the former pro-
ducing effect by a chemical alteration of poison
which renders it harmless, while the effect of
physiological antidotes is produced by their
action upon poisoned organs of the body, and by
restoring their disordered functions. He argues that while, in the nature of things, chemical antidotes are harmless, the physi-
ological antidotes must be themselves poisons.
Applying this view to Behring’s serum it is inferred
that if its harmlessness be proved, it must be a
chemical antidote capable of rendering the poison
harmless by means of a chemical alteration taking
place in the fluids of the organism. He considers,
moreover, that an antagonistic influence may be
exercised over the pathogenic micro-organisms in
two ways, and that while the cells resist the
action of the parasites, substances are developed in
the animal fluids which are capable of rendering
the poisonous products of the bacilli harmless.
The development of these substances, however, would
appear to be determined only by the actual cause of
the disease (Pharm. Zeitung, xxxix, 874).

Snake Poison.*

BY PROFESSOR W. D. HALLIBURTON, F.R.S.
A complete investigation into the subject of snake
poison must attempt to answer three questions:—(1)
What is the poison? (2) What is its physiological
action? (3) How can one best prevent or counteract
this action?

Dr. C. J. Martin’s papers relate to the first
two questions only. The method of obtaining the poison
was an ingenious modification of that adopted by
the Indian snake men. The yield of poison per bite
was very small, and so considerable time and patience
were consumed in getting enough material to work
with. The small quantity secreted is apparently amply

* Extracted from an article in Science Progress.
atoned for by quality, the minimal fatal dose per pound weight being considerably less than that given by the Indian Snake Commission for the cobra. Some value of this virulence may be gathered from the fact that one-thousandth part of a grain invariably kills a rabbit of five pounds weight in about a hundred seconds. This extraordinary toxicity becomes more astounding still when we consider that the poison is a protein undistinguishable by chemical methods from those daily used as food by all of us.

The first investigation of any importance into the chemistry of the snake poison was by Prince Lucien Buonaparte, in 1843, on the poison of an adder. He found that the activity of the poison was associated with that portion precipitated by alcohol; and he gave the name "viperine" to this precipitate. Dr. Weir Mitchell next turned his attention to the subject about 1860; and he is essentially the founder of our present knowledge concerning snake poison. Crude as were the methods of animal chemistry in his day, they nevertheless led him to the right conclusion that the toxic principle of the venom is albuminoid in nature. He termed it "crostallin" in the case of the rattle-snake. From that time till 1886, in conjunction with Reichert, he continued his work, and confirmed his general conclusion in the case of other North American snakes. About 1871 the Indian snakes received their share of attention; and the names of Sir Joseph Fayrer and Dr. Lauder Brunton are associated with valuable researches concerning the venom of the cobra, kraits, and the Indian viper.

In 1883 Wall, in 1886 Wolfenden, and in 1893 Kanthack, published most instructive contributions to our knowledge of cobra venom; the improved methods of chemical physiology enabling them not only to identify the poison as a protein, but to show that the variety of protein present is an albumose. Two observers only of importance have described poisons other than a protein in snake venom: one of these was Gantier, who regarded the venomous principle as alcaloidal; and the other, Winter Blyth, who gave the name "cocco acid" to a highly poisonous crystalline substance he claimed to have separated from cobra venom. Recent work has failed to substantiate these results, and alkaloids when present at all (they are generally absent) are non-poisonous ones.

In the researches on the venom of the Australian black snake, Martin and Smith* found it necessary to exclude various classes of poisons, as well as to determine positively the nature of the venom. They excluded in the first place by appropriate experiments the presence of micro-organisms, ferments, alkaloids, ptomaines, and crystalline acids.† In the second place they showed that the poison was a protein. The methods for the separation of proteins from one another are highly technical. It will therefore be sufficient to say that the manipulations were of the most careful and exact kind and pass to the results obtained. In the proteid mixture three proteids were obtained: one an albumin, and the other two albumoses. The albumin is not virulent, but the two albumoses (corresponding to proto- and hetero-albuminoses of Kühne) are extremely poisonous. They each have the same physiological action, and this is the same as that produced by the venom itself. The venom can be momentarily boiled without impairing its activity, but prolonged boiling for days destroys its virulence.

(To be continued.)

PEPPERMINT OIL.

An extended investigation of this oil by Power and Kleber has shown the presence of the following constituents (vide Schimmel's Berichte):—

Seventeen different samples of oil were examined, two of them being prepared from specially selected material in Messrs. Schimmel's factory, and the physical character of all of them was determined. The results show, that the specific gravity of peppermint oil varies between 905 and 916. The rotatory power is very variable—ranging from -25° to -35°—and it does not appear to have any direct relation to the amount of menthol. The menthol present in a free state may vary from 24.2 to 72.7 per cent, and the menthol present in the state of ester may vary from 3.45 to 14.15 per cent. For determining the amount of free and combined menthol the oil is treated by the process described at page 458 of the present volume of the Journal. The results obtained is slightly affected by the presence of other esters besides menthol acetate, but the error is too small to be of importance. From the convertibility of menthone into menthol by reduction with sodium it is also possible to determine the amount of menthone.

Applying this method of menthol determination to fractionated portions of the seventeen samples of oil, the results given in the annexed table were obtained:

† A questionable trace of an organic acid found did not possess toxic properties.
The Registrar was directed to remove his name from the Medical Register.

No one who is acquainted with the drug trade can doubt that a similar power, vested in the Council of the Pharmaceutical Society, would exercise a wholesome influence, and be productive of beneficial results. The power which the Privy Council has, under section 26 of the Pharmacy Act, to direct the name of a person convicted of any offence against the Act to be erased from the Register of Chemists and Druggists, has never been exercised, and probably the Privy Council is too far removed from cognisance of the conditions obtaining in the drug trade to admit of the power being exercised even from a public point of view.

It is in regard to action detrimental to the general interests of the chemists and druggists, that the power of permanent or temporary erasure from the Register is desirable, but it is unnecessary to do more than speak in general terms of the necessity for such a power as a controlling influence, and if requisite, as a means of duly punishing offences. In the paper recently read before the Manchester Pharmaceutical Association by Mr. Taylor, reference was made to several matters which might be appropriately dealt with in that way, and we fully agree with the opinion that, if the power existed, observance of ethical principles would soon be developed as a natural consequence. Meanwhile the procedure adopted by the General Medical Council in reference to offending members of the medical profession may be instructive.

In addition to the steps taken for removing names from the Register, the Medical Council has recently been active in regard to the improper employment of unqualified assistants, and has recorded on its minutes that in the event of cases being brought before the Council in which there is evidence of misconduct in that respect, they will be regarded as charges of infamous conduct. The Lancet, in commenting upon this decision, remarks that, although the practice of employing unqualified assistants has been customary from time immemorial, there are grave public and professional reasons why it should be reduced to a minimum. Since the medical practitioner is supposed to be registered as a qualified person, the public has a right to expect that it will receive authorised medical assistance from him in case of need. The practice of placing an unqualified assistant in charge, perhaps at a distance from the residence of the principal, and under his name of allowing such assistant to deal with patients, is admitted to be unjust to the patients, and, in some instances, even worse. The evil is sometimes even the result of connivance on the part of qualified persons who take no other part than that of facilitating evasion of the Medical Act by lending their names to cover unqualified persons. Our contemporary acknowledges that, while the
public is deceived the profession is injured, and much of the undignified work which brings the profession into discredit is referable to the practice of employing unqualified assistants. Finally, it is urged that, as an obligation due to the profession, the Medical Council should insist upon a sharp line of demarcation between the qualified and the unqualified, and should not allow registered practitioners to enable unqualified persons to act as if they were duly qualified.

THE REVISION OF THE BRITISH PHARMACOPEIA.

The want of a revised Pharmacopeia is sufficiently urgent to make any possible postponement of its issue a matter for regret, and, in that sense, the apparent existence of conflicting opinions as to the proper nature of the work and the mode in which its revision should be carried out cannot fail to attract the attention of pharmacists. In our issue of the 16th inst. the full text of the Report of the Pharmacopeia Committee of the General Medical Council was published in the form that it was received and entered on the minutes. In consequence of objections raised by some members of the Medical Council to the original draft of the report, the motion for its adoption was met by an amendment, which was carried on a vote being taken. On reconsideration of the matter it was agreed that certain questions should be left open for further consideration, and that the constitution of the Pharmacopeia Committee should be brought before the Council at the meeting in May next.

One of the objections raised to the original draft report of the Pharmacopeia Committee was to the effect that, under the proposed arrangements, the new work would be purely a pharmacist's Pharmacopeia; and, in the course of the discussion, Dr. Glover stated that the Council would not be at all satisfied unless provision were made for some sort of recognition of the therapeutic side of the subject, which he suggested might be done by appointing a therapeutic editor as well as a pharmaceutical editor. This idea of introducing therapeutics into the Pharmacopeia, and making it not only the standard and guide whereby the nature and composition of substances used in medicine may be ascertained and determined, but also an authoritative work on the medical properties and uses of drugs, points to an entirely new departure. It appears to be suggestive of some confusion of the modern interpretation given to pharmacology, with the purposes for which Pharmacopeias have hitherto been intended. That medical opinion and usage should have a preponderating influence in determining what a Pharmacopeia shall contain is self-evidently appropriate, and ample provision for control in that respect appears to have been made by the recommendation of the Pharmacopeia Committee that the medical authorities of Great Britain and Ireland should be asked to assist in the compilation of the new Pharmacopeia, and that a consultative committee, consisting of the President of the Council, Sir John Duckworth, Dr. Leech, and Mr. Brunnenell Carter, should be appointed to confer with the Editor, presumably in regard to the medical aspect of the work.

But the introduction of matter relating to the recognised action of drugs, is a proposition which would go far beyond the limits of any Pharmacopeia in existence, and, as Sir Richard Quain remarked, it would take years and years of investigation before a satisfactory result could be arrived at. Moreover, if that difficult task were attempted, it would probably be attended with undesirable consequences. It might be expected to favour the production of an extra Pharmacopeia indicating the uses to which medicines might be applied, and bearing the title of ‘Every Man his own Doctor.’ In the discussion at the Medical Council, Mr. Brunnenell Carter objected to such an interpretation of ‘other matters and things,’ which the Council is empowered to introduce into the Pharmacopeia. These relate to the list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed. In a letter to the Lancet last week he further contends that grammatical construction of the words in the Medical Act affords no justification for converting the Pharmacopeia into an analogue of ‘Whitaker’s Almanac,’ by adopting the suggestion that it should state the supposed curative properties of medicines. In his opinion the Pharmacopeia should have the one object of securing uniformity of strength and composition in all preparations which are sold under certain names. Mr. Carter further mentions the introduction of synonyms as being within the province of the Medical Council, in order to prevent such practices as the sale of paregoric elixir without the opium which is properly an ingredient of the compound tincture of camphor, or any similar alteration of the composition of official medicines.

From that point of view the addition or omission of articles should be governed solely by consideration whether the articles in question are sufficiently used by medical practitioners to render uniformity in preparing them a matter of importance. In regard, also, to the exclusion of drugs or preparations which are inert or useless, prevailing medical opinion must, of course, decide what is desirable, and for these purposes the proposed Consultative Committee, assisted by the medical authorities of the kingdom, would suffice. We thoroughly agree with that view, and in that sense the Pharmacopeia may be properly regarded as essentially the pharmacist’s book, the rule and guide.
of his practice, mainly to serve the purposes and requirements of medical practitioners. Any attempt, however, to expand the Pharmacopoeia into a treatise on pharmacology or a guide to the uses of medicines, though introducing matter relating to its proper subject, would be an unwise interference with private authors, while committing the Council to current hypotheses which time might not confirm.

BRITISH PHARMACEUTICAL CONFERENCE.
Judging from the figures supplied by Mr. Henry Mathews, the local secretary at Oxford of the British Pharmaceutical Conference, the result of the arrangements as carried out at the latest meeting is exceedingly satisfactory, and should prove decidedly encouraging to other small towns that may hesitate to send an invitation on the score of expense. It will be remembered that a slightly higher price than usual was charged for the Oxford tickets. The total amount received was £173 3s. 0d., and, against this, the expense of the whole of the entertainments, from Monday to Thursday inclusive, amounted to £186 12s. 0d. only, so that there was but a small deficit. This was once subscribed by a few members of the local committee, and it has been rendered unnecessary to solicit pecuniary assistance from the committee generally, or from persons outside the craft. The small increase in the price of the tickets is thus quite justified, as tending to keep the Conference in a position of independence, and Mr. Mathews is to be cordially congratulated on this successful termination of his labours as local secretary to the Conference.

PRODUCTION OF OZONE.
According to Engineering, the most recent method of producing ozone—that of Lieutenant Poulsen, a Danish officer—is based on the oxidation of phosphorus in a special apparatus. A wide-necked glass jar is closed with a finely perforated porcelain plate, and two inches below this is a similar plate inside the jar. Through the centre of each passes a glass rod, which is curved upwards at the lower end and terminates in a small cup for holding a piece of phosphorus. The jar contains sufficient acidulated water to submerge the phosphorus when the apparatus is not in use, and, when ozone is required, a small quantity of potassium permanganate is added to this, and the phosphorus raised by means of the glass rod above the surface of the liquid. Phosphorus acid is formed by contact of the phosphorus with the air, and converted into phosporic acid by the action of the permanganate, whilst, simultaneously, ozone is produced and escapes through the perforations in the porcelain plates.

COAL-TAR COLOURS.
Mr. A. G. Green's English edition of the 'Systematic Survey of the Organic Colouring Matters,' published by Drs. Schultz and Julius six years ago, contains an interesting historical account of the coal-tar colour industry. Although only between thirty and forty years old the industry now employs some 40,000 operatives, including over 500 trained chemists; and the annual value of the product extends to millions of pounds. Although such large numbers of new dyes are constantly being discovered and patented, it is said that less than one hundred varieties are in actual use on a large scale, the remainder failing to show the necessary permanence.

PATIENTS AND MEDICAL TREATMENT.
Prescription of the inability of patients to decide for themselves on the very difficult question of medical treatment would suggest to a logical mind the necessity of relying upon the judgment of properly qualified medical men whose lives have been devoted to the study of disease. Lord Coleridge, however, has made use of that circumstance as furnishing an argument against the use of antitoxin in hospitals and to support the opinion that only such treatment should be adopted as has been "proved to be a cure." The British Medical Journal justly ridicules this view of the matter as unreasonable and misleading. It indicates precisely that mental condition which offers a field for exploitation by the quack and the charlatan, not only among the ignorant multitudes but above all among persons of better education.

THE USE OF MAKE-SHIFT APPLIANCES.
Adaptability to circumstances and the power of turning existing conditions to account are no doubt potent factors in the survival of the fittest, and the British Medical Journal relates an instance in which these faculties were displayed by a bacteriologist who, having occasion to make experiments without the usual appliances, captured a hen, and fixed his culture tubes under her wing, with the result of obtaining the effects required. It is also mentioned that Marion Sims' first speculum was the handle of a kitchen spoon, and that Sir William Ferguson is said to have amputated at the shoulder with a pocket-knife.

DANGERS OF PROMISCUOUS DRUG-TAKING.
Dr. Stanley Melville, of Southport, in a letter to the Lancet, directs attention to the danger attending the promiscuous use of such drugs as antipyrine, and reports a case in which he was called to attend a lady in a state of extreme collapse, whose condition was for some time most serious notwithstanding the prolonged efforts to revive her. After her recovery Dr. Melville ascertained that, on the advice of a friend, she had taken antipyrine
which she had no difficulty in obtaining, and of the potency of which she had no idea. On being remonstrated with, she remarked, "Why, my dear doctor, all my friends take it!" Dr. Melville expresses the hope that, after his patient's experience, those friends may see the error of their ways, though he is less hopeful for the unfortunate who have not such an experimental warning to draw clinical pictures for their benefit. Surely this, and many other of the modern synthetic remedies, should be included in the Poisons Schedule.

MANCHESTER PHARMACY BALL.

The second annual ball and musical promenade of the Manchester Pharmaceutical Association will be held at the Hulme Town Hall, Manchester, on Wednesday, January 23, 1895, when the doors will open at 7.30 p.m., the musical promenade commence at 8 p.m., and dancing begin at 9 p.m. Mr. E. S. Johnston will officiate as M.C.; the music will be furnished by Mr. J. H. Greenwood's band, and refreshments by Mr. Max Weigenthaler. Tickets, including a glass of light refreshment (double tickets, 12s. 6d. each; single tickets—gentlemen, 8s. 6d. each; ladies, 5s. each), may be obtained at the hon. secretary, Mr. A. Blackburn, 7, Exchange Street, Manchester. Applications for tickets for others than members must be accompanied by a recommendation from a member of the Association, or one of the stewards of the ball, and early application is requested, as the number is limited.

CHEMICAL SOCIETY.

Two papers were read at the meeting of the Chemical Society on Thursday last. In the first, on the chemical constituents of Piper argenteum, by Dunstan and Garnett, it was stated that an inert resin and a crystalline substance, having many of the properties of an alkaloid, but not possessing any basic power, had been extracted from the plant. The latter compound it is proposed to name "piperovatine." It forms colourless needles, which melt at 123° and are nearly insoluble in water, light petroleum, or dry ether, but dissolve readily in alcohol, chloroform, or acetone. The alcoholic solution gelatinizes on adding water. Piperovatine is optically inactive, and its formula is C_{18}H_{12}NO_{3}. It appears to be nearly allied to piperine, and is apparently hydrolysed by acids and alkalis, producing a pyridine base—possibly piperidine—and an acid. The physiological action of the base has been examined by Professor Cash, who finds that it acts as a temporary depressant of both motor and sensory nerves. It is a heart poison and acts on the spinal cord in frogs, causing a tonic spasm like that produced by strychnine.

In the second paper, by the same authors, it was stated that the active constituent of pellitory, Anacyclus pyrethrum, had also been separated in a crystalline form. This it is proposed to name "pellitorine." In most of its physical, chemical, and physiological properties it closely resembles piperovatine, possessing the general structure of an alkaloid, but being devoid of basic or acidic properties. It is possible that the two compounds may prove to be identical.

MISCELLANEOUS NOTES.

REPORTS of two cases of interest to pharmacists, heard in the Court of Session, Edinburgh, on Monday, will be found at pages 554 and 555.

On December 19 the chemists of Newcastle and district held their fifth annual ball in the Old Assembly Rooms, Westgate Road, Newcastle. About fifty couples were present, and a most enjoyable night was spent. Messrs. James Davidson and A. R. Bennett were the M.C.'s, and the following gentlemen acted as stewards—Messrs. F. A. Bowneith, G. Cormack, R. S. Hull, R. McClempth, W. Westhead, and J. W. Whittle. The music was supplied by Mr. E. R. Corbett's band. Dancing came to an end about 2.30 a.m.

At the recent election of guardians at Louth, Linco., Mr. H. G. Smirson, chemist and druggist, was elected at the head of the poll.

A bacteriological institute is about to be established at the University of Kieff at an estimated cost of £10,000, and a well-known pharmacist of Moscow has given a house valued at £3,000, with £500 in cash towards fitting it up as a bacteriological laboratory.

By a decision of the Kentucky (U.S.A.) Court of Appeals recently recorded, the State revenue authorities are upheld in the imposition of a special tax of $50.00 per annum upon druggists for the privilege of dispensing spiritsuous liquors for medicinal use.

It is stated by a Daily News correspondent that an attack of purulent pneumonia at present prevailing in Paris originated in a cargo of green parrots landed some years ago at Bordeaux.

Some time ago reference was made to the fact that steps were being taken to carry out a system of Russification at the University of Dorpat. It is now reported that the system has been carried out in such a rigorous manner as to lead to a protest by the students, who have ceased attending the lectures in the hope that the attention of the Tsar may be attracted to the matter.

At Alais, in the department of the Gard, a laboratory is to be established for the supply of antidiphtheritic serum, and the idea is being warmly supported by the townpeople and local authorities.

A considerable number of pharmacists have been elected to serve upon the newly-constituted Parish Councils, and we notice that at Hurspierpoint the third place upon the list of successful candidates is occupied by a lady—Flora Mitten, pharmaceutical chemist.

The Chemists' Assistants' Association held a musical social evening on Thursday, December 20, when the chair was taken by Mr. J. C. Uney. The programme consisted of songs, pianoforte solos, and recitations by members of the Association and their friends. Messrs. H. Browne and A. C. Mackadam acted as accompanists, and the programme was under the direction of Mr. F. C. Long.
Proceedings of Societies in London.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting was held on Thursday, December 13, Mr. T. A. Henry, Vice-President, in the chair. A paper was read on—

A PEBBLE OF GRANITE.

BY HAROLD READ.

The essayist commenced his paper by contrasting the varieties of British granite which occur in Aberdeenshire, at Shap Tor, near Penrith, and in Devon. He then discussed its lithological characteristics, and touched on the older, as well as mentioning the more modern, theories as to its formation in the presence of superheated steam and under great pressure. He showed that it could not have formed in the same way as the volcanic rocks of the present day, since brocias, rhyolites, etc., are never found associated with granites. The well-known example at Priestlaw was described as a case where granite could be formed by extreme metamorphism.

The various kinds of metamorphism produced by granite on adjoining rocks were illustrated by specimens.

Mr. Read then discussed the petrological characteristics of granite, describing the physical properties of the quartz, felspar, and mica.

The weathering of the rock was then treated, and the various decompositions of the constituents explained. It was shown how the silica and mica might be partially dissolved and washed away, the alkali silicates of the felspar decomposed by the carbonic acid gas in solution in rain water, and the soluble biocarbonates of calcium, potassium, etc., dissolved and carried away, the insoluble hydrous silicate of aluminium or kaolin being left.

In addition to several characteristic specimens of granite, its constituents and its products, the author exhibited several interesting microscopic slides illustrative of his subject.

A beautiful specimen of red granite from Mount Sinai, lent by Professor Atfield, was most interesting, attractive, and unique.

The paper gave rise to a discussion in which the Chairman, Miss Buchanan, Messrs. Wright, Brown, Tynbridge, Smith, and the Secretary took part.

The paper and discussion having occupied a considerable time, the paper on "Volumetric Analysis," by Mr. Burgess, was postponed to the next meeting, and the proceedings terminated.

CHEMICAL SOCIETY.

A meeting of the Chemical Society was held on Thursday, December 20, the President, Dr. Armstrong, F.R.S., in the chair.

The following papers were read—

AN IMPROVED FORM OF BAROMETER.

BY DR. N. COLLIM.

The objections to the ordinary form of barometer are the weight of the instrument due to the amount of mercury employed, and the want of portability, owing to the tendency of the mercury to escape.

The form now produced obviates these difficulties.

The cistern containing the mercury reservoir is sealed on to a piece of capillary tubing such as is used for Sprengel pumps, and a side piece is sealed on to the cistern, and a tap fitted, so as to ensure connection with the atmosphere.

Sprengel tubing is used to connect the mercury in the lower and the top cisterns, which should be made of the same piece of tubing. The top cistern is sealed on to the Sprengel tubing in such a way as to form an air trap. The end of the Sprengel tube is blown out into a bulb, and the end of the cistern is drawn out so as to end in a fine tube, which projects into the bulb formed by the Sprengel tube. The joint is made by the bulb and the body of the cistern. By this means any air which might be present in the Sprengel tube collects in the trap and not in the Torricellian vacuum in the top cistern.

The Sprengel tube is connected to the lower cistern in the following way: it is prolonged into a fine tube of capillary bore, which dips almost to the bottom of the cistern, and is so bent as to follow the curve of the side of the cistern. By this means connection is obtained between the mercury in the two cisterns. The whole is mounted against a piece of plate glass with a millimetre scale etched on one side, and mirrored on the other. In reading, the scale is read so that only one line is visible to the eye, and hence all error of parallax is avoided.

If necessary, the barometer can be made in two pieces, the capillary tube being divided in the centre and then one part ground to fit into the other. By this means the barometer can be read by difference to \( \frac{1}{4} \) mm., and it can easily be filled and stored.

THE CHEMICAL CONSTITUENTS OF PIPER OVATUM.

BY PROFESSOR DUNSTAN, F.R.S., AND H. GARNETT.*

NOTE ON THE ACTIVE CONSTITUENT OF THE FELLITORY OF MEDICINE.

BY PROFESSOR DUNSTAN, F.R.S., AND H. GARNETT.*

THE MEASUREMENTS OF HIGH TEMPERATURES BY THE PLATINUM PYROMETER.

BY G. T. HAYCOCK AND F. H. NEWVILLE.

The melting point, or, more accurately speaking, the freezing point, of several metals has been determined by means of the Callender-Griffith pyrometer, which depends on the following principle:—When a current of electricity is passed through a platinum wire a certain resistance is encountered which can be measured; if the platinum is subject to alteration of temperature the resistance also alters, and this variation can be measured. The standards of the instrument are determined by comparison with an air thermometer, and also by measuring the resistance when the platinum is at the temperature of melting ice, boiling water, and boiling sulphur.

The freezing points of several metals are given, and found in most cases to approximate to those previously determined, with the following exceptions:—

- Magnesium, formerly 600-800°, now 633°.
- Aluminium, 600°, 653°.

* The report of these papers which were to have been provided had not arrived at the time of going to press. See summary on page 550 [Ed. Pharm. Journ.]
Since large quantities of metal were required in these experiments, it could not be chemically purified, so the purest obtainable in commerce was used and several specimens from different sources examined.

THE PREPARATION OF ADIPIC ACID AND SOME OF ITS DERIVATIVES.

BY DR. W. H. INCH.

In order to prepare a large quantity of this acid several methods were tried, but in all cases with unsatisfactory results.

The most satisfactory method was found to be that of Wielooenus* (A. 149, 221), and consisted in treating β-Iodo-propionic acid with silver, when condensation occurs, and adipic acid and silver iodide are formed—

\[ 2\text{CH}_3\text{CH}_2\text{COOH} + 2\text{AgI} \rightarrow \text{CH}_3\text{CH}_2\text{COOH} \]

But the difficulty in this case is the preparation of the β-Iodo-propionic acid, which has to be prepared from glyceric acid and phosphoric iodide, and the yield of glyceric acid from glycerin by oxidising with nitric acid was so small that only very small quantities could be prepared.

The other methods given are by the oxidation of sebacic acid with nitric acid (‘Laurent, Ann. de Chemie’ [2], 66, 166) and by the oxidation of fats with nitric acid, in which, however, the sebacic acid is supposed to be an intermediate product.

The author, in repeating the experiments, found that by no method of oxidation could he obtain anything but a minute quantity of adipic acid. When fats are treated with nitric acid, sebacic acid is formed, but very little adipic acid. From the small quantity of acid obtained by Wielooenus’ method the author formed the bromo-derivative, which on treatment with water yields the corresponding hydroxy-derivative.

THE LATENT HEAT OF FUSION.

BY HOLLAND CROMPTON.

The author has endeavoured to trace the connection, if any, between the latent heat of fusion of the elements and their compounds and their chemical constitution. He found that in many cases the entropic change, which is represented by the product of the latent heat and atomic weight divided by the absolute temperature of fusion, is proportional to the valency of the element. Or if \( \eta \) be entropic change, then \( \eta = CV \) when \( C \) is a constant.

He found that in compounds the law seems to hold good for the sum of the valencies of the elements in the compounds.

THE CONDITIONS OF REACTION OF HYDROGEN CHLORIDE WITH THE ALKALINE EARTHS.

BY V. H. VELEY, M.A.

The author found that if HCl be very carefully dried over phosphoric pentoxide or lime no reaction took place at temperatures from 10°-40°, when the gas is placed in contact with dry lime. Similarly there is no reaction at temperatures below 40° with magnesia, though magnesia is most difficult to obtain in the dry condition. With barium oxide action always occurred, and this was probably due to the incomplete drying of the oxide.

A paper on the interaction of bismuth haloid compounds and hydrogen sulphide, by M. M. Pattison Muir, M.A., and E. Eagles, B.A., was taken as read.

Scottish Transactions.

EDINBURGH PHARMACY ATHLETIC CLUB.

The third annual smoking concert of the Club was held in the Imperial Hotel, Edinburgh, the 19th inst., at 8.30, Mr. David MacLaren in the chair. There was a large attendance, and an excellent programme of vocal and instrumental music made time pass rapidly and pleasantly. Mr. Jaap, of the Edinburgh Harriers Club, gave a fine exhibition of Indian club exercise. The arrangements were in charge of the Hon. Secretary, Mr. J. F. Gibb. The Club Rooms, at 79, Leith Street, are now open for the season, and members are provided with keys to enable them to use the rooms at any time.

American Pharmaceutical Association.

THE DEMANDS OF PHARMACY UPON ITS GRADUATES.*

BY W. W. KERR.

It augurs well for the future of pharmacy in the United States that so much attention is being paid, in recent years, to the preliminary education of those who are to engage in its practice hereafter, and to the discussion of the question of what should constitute that initial training. It is a healthy outgrowth of the impression that has been slowly but surely fastening itself upon the minds of pharmacists themselves, that theirs is a learned profession, taking rank with the other learned professions, and like them demanding a peculiar fitness and a special training. This impression has been years in taking shape and formulating methods, but it is just now experiencing a spirited revival as the result of its reflection from the profession to the people, where it has crystallised into pharmacy laws, and is now, by reflex action, coming back upon its originators in the shape of louder and more exacting demands for higher education. There is no longer room for discussion as to the necessity for this special preliminary training, nor limit as to the height to which it should be carried, but the question is—in what shall it consist? What shall constitute the armament of those who are turned out from our schools as competent to dispense the physic upon which the lives of thousands hang? It of course rests with the colleges of pharmacy to determine the methods by which the instruction may be best imparted, and largely as to the extent to which it should be carried; but as demand must always regulate the quality as well as the quantity of the supply, their curriculum must be to a great extent measured by the demands of the profession at large, and it is therefore pertinent that those demands should be made known from the standpoint of the consumer, that the supply may be regulated accordingly, and it is to this fact that this paper owes its existence.

In this discussion, as in most others, there are two extremes and two parties, the one tending to the one

* Read at the Asheville meeting, 1894.
pole the other to the other, which is probably the best way to determine the “happy medium” along which the true policy usually lies. Very naturally the tendency of the teacher of pharmacy is in the direction of the higher scientific education of the student in preference to the more practical, while with the officinall pharmacist—if I may be allowed to resuscitate an old word and give it a new meaning—the tendency is toward the practical rather than the scientific. I would not be construed as under-rating the great advantage of a careful, technical education, or under-estimating the substantial progress being made of late years by the schools, in the direction of the practical, but, on the other hand, I heartily recognize and appreciate both, and am simply desirous of contributing towards the further promotion of the latter, without in any degree lowering the standard of the former.

The young graduates, when they leave college, enter the service of one of two patrons; the retail pharmacist, as clerks, or the public, as proprietors. By far the larger part probably assumes the first relation, and as the requirements in either case are substantially the same, it will be sufficient to ascertain the “demands of pharmacy upon its graduates.” Now practical pharmacy includes three classes of duties, which may be set down as professional, comprising the identification, preservation, testing, compounding, and dispensing of drugs and chemicals; manipulative, embracing the care of the stock, its proper display, the ornamentation of the store, etc.; and the commercial, or buying and selling, and generally the business management. A fair knowledge of these several classes of duties in all of their details will be exacted by the employer of those who come to him as applicants for positions as skilled assistants; these taken together make up his estimate of competency. If a diploma from a first-rate college of pharmacy is supposed to be a guarantee that its holder is fully competent—professionally, morally, and every other way—to discharge the duties pertaining to the practice of pharmacy, and when presented to a prospective employer, has a right to be so recognized; and if things that are equal to the same thing are equal to each other, then the diploma and competency are, or should be, interchangeable terms. But is it possible to meet the conditions of this axiomatic formula?

Possibly with our present facilities it is not and may never be, and yet the demand is not unreasonably exacting, and will not be lowered, and hence must ever remain the goal of pharmaceutical teaching; though like the circulating decimal, it is ever approaching and never reaching, it must go on and on in that direction.

Several conclusions may be drawn from these considerations. It would lengthen this paper too much to attempt to cover the whole ground. Two or three lying nearest the surface must suffice.

The first is, that the diploma of a college of pharmacy must represent a greater or less amount of practical experience. This must follow if it be admitted on the one hand that experience is an element of fitness, and contended on the other that those institutions are competent to perfect that fitness. That this is a difficult feature of the contract is not denied. To fit the student for the proper discharge of the first class of duties mentioned above is easily within the reach of the college curriculum, but to include the other two is, for obvious reasons, more difficult, and can only be compassed by resorting to the only source of supply at present available, and that is the shops where the business is conducted. It is hardly sufficient to urge that it is unfair to exact of a college faculty to certify to a proficiency which is not in their power to confer, and of which they can have no personal knowledge. If practical experience is an essential pre-requisite of a finished pharmacist, then somebody must be responsible for its presence. Certainly the future proprietor cannot be expected to “go back of the returns” and invest his money and his reputation in an experiment upon which such grave issue hang; the State boards of pharmacy have no means of recognizing its quantity or its quality, not enjoyed to a greater degree by the colleges, and so it is thrown back upon those who labelled the package to become responsible for its contents—and hence the great work before our schools should be in the direction of overcoming the difficulty rather than urging it as an argument for shifting the responsibility upon some one else.

A second deduction is that the practical training should be contemporaneous with the college course rather than before or after it. When it precedes it the trouble lies in determining its character from want of personal knowledge as to whether it was obtained in a saloon with a patent medicine attachment, or in a legitimate pharmacy, and, if in the latter, whether at the cigar or prescription case. The same is true to a great extent when it succeeds it. But when both are carried along together, the practice forming a part of the course, as it were, as far as possible in the vicinity of the school, and to some extent under the eye of the teacher, the difficulty will be largely overcome. But here again the impracticability of the scheme, in most cases, will be urged against it. In this age of progress the impracticable is fast ceasing to be an impediment to the onward march of improvement; it is becoming an obsolete term in pharmacy as well as elsewhere. While it is true in the cities where our schools of pharmacy are located that employment could not be found for all the students within their walls, there are hundreds of pharmacies all over the country, including many of the smaller towns, conducted by professional proprietors on a professional basis, and where in many respects the very best practical training can be obtained, which by proper concert of action with the colleges might be utilised to supply the demand. The fitness of these establishments can be easily ascertained through the several State associations and the boards of pharmacy, if a systematic and united effort in that direction were organised, and as timetables roll on their number will increase, until the great end to which the whole movement looks be accomplished, when any drug store in the country will be a fit school for training our students of pharmacy in the practical duties of their profession.
Finally, it may be seriously doubted whether our colleges of pharmacy have yet done all they can within themselves towards perfecting this branch of a finished pharmaceutical education. What has been accomplished justifies the prediction that more may be. There are fixed principles underlying business and the general management of a store, just as in the case of pharmacy proper; and why may not these be formulated into lectures and other methods of imparting instruction, which will be as effective in shaping and guiding the future course of the students? That teacher has largely failed in his work who does not succeed in impressing his own individuality and his own methods upon the minds of his pupils—who does not impress them with the idea that he is the best preceptor in the world in his particular line; and why may not this influence be exerted in the direction of fixing sound business principles and correct manipulative methods, as well as pharmaceutical skill? The increase in the length of the course from two to three years, already adopted by some institutions and contemplated by others, will afford increased opportunity for including this sort of teaching in the regular curriculum, and the demands of pharmacy upon its graduates call loudly for the innovation.

Parliamentary and Law Proceedings.

PROCEEDINGS IN THE SCOTTISH COURTS.

ACTION FOR SLANDER AGAINST THOMAS KEEATING.

In the Court of Session, Edinburgh, on December 24, the trial took place before the Lord Justice-Clerk and a jury, of the action raised by William Foster, wholesale dyer, oil and colourman, 94, High Street, Edinburgh, against the partners of the firm of Thomas Keating, insect powder manufacturers, 12, Bride Lane, London.

The plaintiff sued the defendants for payment of £1000 as damages for slanderous statements alleged to have been contained in the advertisement in an action instituted by Keating against the present plaintiff. In that action it was sought to have Foster interdicted from selling Keating's insect powder, insect powder which was not manufactured by the firm. In his statement of facts the plaintiff stated that the defendants did not sell their insect powder in less quantities than sixpenny packets or tins, and that the powder classes could not afford to buy so much at a time. Other equally good insect powders were sold in penny and twopenny packets and on account of their cheapness and excellence had obtained considerable sale in preference to Keating's sixpenny packets. The defendants, he said, became aware of this, and conceived in consequence great ill-will and malice towards the vendors of rival insect powders, and especially against those who sold it in pennyworths. The defendants adopted schemes to suppress, if possible, the sale of these powders, extort money from the vendors of them, and at the same time advertise their own insect powder. With that view they circulated numerous advertisements, such as the following:—

1. "I call attention to the case below. As a matter of fact, I took this course last year, and in the end the reward and heavy costs came out of the substitution of the commonest, and I have every reason to believe that the course I adopted was highly satisfactory to the neighbouring chemists, as well as to the public and myself. In the case of Keating v. Kibble, the heading 'A Storey Caught,' the case of Keating v. Kibble was referred to. The plaintiff averred that the import and meaning of these advertisements was (1) that disreputable persons might easily earn £5 by concocting evidence which would support actions such as Keating v. Kibble; (2) that they were written, without the knowledge of their masters to substitute another insect powder when Keating's was asked for, and then inform Thomas Keating thereof, and the information would be treated as absolutely confidential, and the assistant would receive £5 for the information. The object of the defendants was by these means to get up unfounded actions of interdict in the Court of Session against traders and others for advertising purposes, and for the purpose of furthering their schemes to suppress rival traders in insect powders, and not for any other purpose involving any legitimate interest they had in a bona fide trade. The plaintiff further averred that in August, 1893, defendants became aware that he sold insect powder in penny and twopenny packets, that they conceived an ill-will against him, and that for the purpose of gratifying their animosity and ruining his character and credit by means of such expedients as those already mentioned, they, in the following October, wrongfully and without probable cause presented a note of suspension and interdict in the Bill Chamber of the Court of Session, to have him prohibited from in any way offering for sale any insect powder not manufactured by them, that is to say, insect powder not manufactured by the firm. The statements contained in that note were to the effect that it had come within their knowledge that the present plaintiff had, for a considerable time past, been in the habit of selling certain insect powder not manufactured by them, as Keating's insect powder, which was inferior to theirs; that on dates named he sold this powder to certain parties, and that for a considerable period he, or those acting for him, had been in the habit of fraudulently using Keating's trade name to denote an article which was not supplied by them; and that he thusjured the great reputation of Keating in order that he might find a ready sale for a spurious and inferior insect powder.

The plaintiff further stated that interferidict was granted against him, but that when proof had been partly led a minute was put in on behalf of Keating which was not manufactured by them, they took the necessary legal steps for protecting their interests, and preventing a continuance of the illegal practice. With reference to the abandonment of the action, they explained that prior to the date fixed for the
proof, the person who had originally informed them of Foster's habit of illegal dealing, and who had received the powders purchased by persons who were to be witnesses, and transmitted them to the defendants, Intimated that he did not wish to give evidence on account of the publicity it would entail. They were doubtful of whether the evidence of the informant was essential to the success of their case, and, as they had engaged to treat such information as absolutely confidential, they resolved to abandon the action rather than disclose the name of the informant, and gave instructions accordingly. They averred that throughout their whole conduct in good faith, that they had run the risk of finding themselves in the plaintiff's enemy, and that they were not actuated by malice in what they did. They therefore asked to be absolved.

The evidence in the action occupied the whole of Monday and part of Wednesday.

The plaintiff, who was the first witness, gave a long statement with regard to the proceedings taken against him by the defendants. He complained that the interdict was served upon him without notice. His agent, whom he consulted in the matter, was greatly inconvenienced because he could not get the addresses of the men who were to give evidence against him until a late hour. After the action was abandoned they burned all the papers which they left him with the charges withdrawn. He gave up selling insect powder, but he found that people came in asking for it, and he had to keep some. The raising of the action against him became known. Travellers and others spoke to him about it, and some even approached on their own accord to put any figure on his loss in business, but he had been subjected to worry and annoyance. Before the action was taken by Keating's people he warned his son and daughter who assisted him in the shop not to sell the insect powder as Keating's.

Several witnesses spoke as to their having been in similar actions in Edinburgh, one of whom said the action against him had been abandoned, but that he might have a claim yet. Other witnesses spoke to having seen the statements against Foster, and said they regarded them as calculated to do him injury in trade. One of them said he knew Foster well, and that after seeing the statements, he made inquiries, and discovered he was using them against him.

Peter Morison, S.S.C., spoke to the conduct of the proceedings complained of by the plaintiff, and as to the grounds on which he made the statement in the present action.

Mr. Wyld, manager for Keating, was examined on behalf of the plaintiff at great length in regard to the advertisements for information. He said he never intended to associate them with criminal proceedings, nor to suggest that the information should be given by disreputable people. He had learned from correspondence in the Chemist and Druggist that a good deal of substitution was going on, and had taken proceedings in England. It was desired by the advertisers to get information to prevent substitution. As to the statements founded on, he acted on the advice of his agents. He did not think the statements made by him against Foster were worse than those which Foster made against him.

Several witnesses were next called, who spoke to the demeanor of the informants in the action in which the defendant had a share, and also to the conviction for breach of the peace against one of the informants in the case against Foster.

Among the witnesses for the defence were Mr. Lambden, the London managing clerk of Keating's, and Mr. Thomas, one of the partners of Keating's Edinburgh agents. Both spoke in regard to the proceedings complained of. Mr. Lambden said the stopping of the proceedings did not depend upon the character of the witnesses in McCallum's case, but because the informant who had sent them the names of the people that got the powder had stated that he was a chemist, and did not wish his name to be revealed until he should pass his examination. When Mr. Wyld was told that he insisted on keeping his information as confidential, and therefore abandoned the action. The proceedings, they said, were conducted in the usual way and under the advice of Counsel. Counsel having addressed the jury, Mr. Wyld observed that the plaintiff was not in any way of which he laid particular stress on the duty of the plaintiff to prove malice in order to make a good case.

The jury, after nearly an hour's absence, returned a verdict for the plaintiff, and assessed the damages at £20.

Counsel for the plaintiff was the Solicitor-General, Q.C. and Mr. T. B. Morison; Agent, Peter Morison, S.S.C.

Counsel for the defendant, Mr. Jamason and Mr. Dewar, Agents; Cornillon Craig and Thomas, S.S.C.

A DRUGGIST SUED FOR HEAVY DAMAGES.

The trial took place in the Court of Session, Edinburgh, on Monday, December 21, of an action raised by Mrs. Margaret Stewart or Lawson, widow of David Law- son, engineer, Glasgow, and David Lawson, John Lawson, and Margaret Jane Smith Lawson, all residing at 2, Andergowan Terrace, Sandiford, Glasgow, and Peter Lawson, Blackford, Perthshire, against John Christie, druggist, 356, Dumbarton Road, Glasgow, in which damages were sought to be recovered—of £1000 by Mrs Lawson, £250 each by David and John Lawson, and £250 each by Peter and Margaret Lawson in connection with the death of David Lawson, the husband and father of the plaintiffs.

On behalf of the plaintiffs it was stated that Mr. Lawson suffered from a complaint of the liver for many years prior to his death, and was in the habit of using internally extract of taraxacum as a remedy. He kept the extract regularly in his house to be available at any moments. He had an hour's supply on Wednesday, May 28, and used all the taraxacum he had in the house, and, not wishing to be without it, he sent his son Peter to the defendant's shop, at 356, Dumbarton Road, on the same day for a fresh supply. At the same time he gave his son sixpence to pay for it, and told him to write to the druggist for a piece of paper and affix it to the jar which held it. When Peter asked for extract of taraxacum he was told by the defendant's assistant that he had none of the solid taraxacum, but gave him a liquid which he said was better than the solid extract. His father sent him back with it, and when he returned to the shop the assistant made further search, and said he had found some of the solid extract. The assistant put into the jar a substance which he said was the extract, and he affixed to it a label on which there was printed the name and address of the defendant, and written "Extract of Taraxacum." He handed it to Peter Lawson twopennyworth of the sixpence, stating that the price was fourpence. On July 14, 1893, at his temporary residence, Lincoln Cottage, Eglington Street, Saltcoats, Mr. Lawson complained of an attack of his liver complaint, and to alleviate it he swallowed a portion of the substance given him by the defendant, which he understood to be solid extract of taraxacum. He remarked to Mrs. Lawson that it had a very bad taste, and that he would take no more of it, and soon after began to feel unwell.

Two doctors were called in diagnosed that Mr. Lawson was suffering from poisoning by strychnine. They administered an antidote, but he died shortly.
afterwards. The plaintiffs said that he died from poisoning by strychnine, and that this was confirmed by a post-mortem examination and chemical analysis of portions of the body, instituted by instructions of the Justiciary Court of the Grand Assizes for the district, to Mrs. Lawson stating that the Crown had concluded the inquiry relative to her husband's death, and that "the death took place through Noble accidentally supplying nux vomica instead of taraxacum." The plaintiffs averred that the defendant and his assistant exercised such a degree of negligence as to warrant a charge of "poison." It was the duty of the defendant so to arrange his stock as to make it impossible that nux vomica or any other substance containing a dangerous quantity of strychnine should be delivered in mistake for any other substance. It was also his duty to employ an experienced and qualified assistant to take charge of the shop in his absence, and to inform him what poisons were kept in stock and where they were kept. He failed in all these duties. The defendant's assistant, for whom he was responsible, acted with culpable fault and recklessness in delivering nux vomica or a substance containing a dangerous quantity of strychnine, instead of taraxacum. The defendant had refused to make reparation, and the present action was necessary.

For the defence it was stated that the substance sold on the occasion referred to was solid extract of taraxacum, and it was explained that about the time of his death Mr. Lawson was in financial difficulties, and was being pressed very hard by his firm to clear off a large indebtedness which he had incurred to them amounting to several thousand pounds, but was unable to do so, being practically insolvent. Defendant denied the statement that Mr. Lawson's death was due to any act or neglect of himself, or those for whom he was responsible.

Mrs. Lawson, widow of the deceased, gave evidence generally in support of the statements on record. She stated that when they went to Saltcoats on July 1, her husband took with him the stuff which her son Peter had bought in Christie's shop on May 28. On July 14 he had a recurrence of his liver complaint. During that day he appeared in good health until the afternoon, between six and seven o'clock, when they were sitting down to tea. He said then that he felt a little "noisy," and he took a quantity of tea, which is about the size of a pea or bean. When he swallowed it he complained of the bad taste it had, and said he would not take any more of it. Very soon after he became ill with jerking and spasms. Two doctors were sent for, who gave it as their opinion that he was suffering from strychnine. They did not suspect any tincture of taraxacum which her husband had taken a portion of before he became ill. They gave him something, but he died about three hours after taking the stuff. Her husband was of a cheerful disposition.

Cross-examined: So far as witnesses knew, her husband had taken nothing between May 28 and the day of his death. Her husband was not affected by business worries. He had no business worries that she was aware of. She came to know that afterwards. She did not know the real state of her husband's affairs at the time of his death. As a matter of fact, he died owing about £6,000 to his firm of Dron and Lawson, and £3,000 to the bank. Her husband's anxiety for his health and future was so extreme that when he pointed the matter out to the pharmacist he gave it as his opinion that he was suffering from strychnine poisoning. On one occasion he took a quantity of the tincture of taraxacum which he had taken a portion of before he became ill. They gave him something, but he died about three hours after taking the stuff. Her husband was of a cheerful disposition.
Dr. Christie brought out the two pots to show how they resembled each other, and not to ask his brother Peter what size of pot the stuff was taken from.

He could suggest no reason why he wanted to show that the stuffs were alike, except that witness did not buy any taraxacum for his father after May 28. He doubtless recollect being in a chemist’s shop in Saltcoats, where Mr. Littlejohn, a druggist’s assistant, had got a refill of the pot of taraxacum. Shown John Clark, assistant to a chemist in Dockhead Street, Saltcoats, witness said he had never seen him before.

John Ritchie Brown, M.D., Saltcoats, deposed to having been called to see Mr. Lawson on July 14. He was lying on the floor when he got there. He answered all the questions put to him correctly. Witness was told that he had taken some medicine in the morning, but witness said if he had taken anything to do him harm it must have been something more recent than that. He was then told he had taken some taraxacum. Witness asked to see the pot in which it was, and found it contained a dark substance. The pot had a label with the name Christie, Dumbarton Road, Glasgow, printed on it, and the word “taraxacum” was written. He could not remember it. Lawson said he had taken taraxacum. There was a great deal of confusion. They were all speaking, and he was speaking incessantly. He could not be positive if he gave any information. Witness was told in Mr. Lawson’s hearing that he had taken some taraxacum. Shortly after Dr. Wallace came in witness drew his attention to the pot. Dr. Wallace tasted it, and contents, and he said it had a sharp, bitter taste. Witness did not taste it. They went into another room, and after a talk, arrived at the conclusion that Mr. Lawson was suffering from strychnine poisoning. They gave him a dose of bromide, but he died almost the moment he swallowed it. They took possession of the pot and the smeared knife with which he took the contents, and handed them to the police.

Cross-examined: The pot was only brought upon his suggestion that it must be something taken lately. It did not seem to have occurred to the family at first to examine it. Witness said it was just after the taraxacum was used that the attacks came on. He could not say positively that Mr. Lawson said so, but he heard it said. The pot was pointed out to witness. The stuff had an extremely bitter taste in his mouth for a considerable time after. Nux vomica and taraxacum extracts were very much like each other. The taste was the only way in which one could distinguish the two. Dr. Brown took the post mortem, but witness was present at it.

Cross-examined: The viscosity of nux vomica and taraxacum was much the same. It was not the case that nux vomica was more viscous than the other. John Watson, a divinity student, second son of the deceased, deposed that after his father was taken ill he sent him to a druggist’s in Saltcoats for threepenny-worth of taraxacum. That was after he complained of being of worse of taking what he thought was taraxacum. He went for it to a chemist in Dockhead Street, and when he returned with it his mother sent him for the doctor.

Cross-examined: He did not know what was done with that taraxacum. He gave it to his mother in the lobby, when she told him to go for the doctor.

Mr. Lawson, recalled and cross-examined as to why she did not say anything when she was first called about the taraxacum which was bought in Saltcoats, said that Counsel did not ask her about it. He only asked her if any taraxacum had been bought between May 28 and the time her husband took ill. The taraxacum now referred to was bought after he took ill. She also said that no use was made of it, he being too ill by the time it was got.

A border of health for Edinburgh, said he analysed a quantity of stuff in a pot which was handed to him by a criminal officer from Kilmarock, and he found in it a sufficient quantity of strychnine to cause death. He reported the results to the Crown. Some days after he got two pots from the criminal officer, which he said were from the druggist’s shop, and he instructed him to ascertain what the contents were. The contents of one was nux vomica, and of the other taraxacum. They were very similar in appearance. They could not be distinguished except by taste or the effects they produced. Taraxacum had no strychnine in it. He was aware of the recommendations issued by the Pharmaceutical Society of Great Britain as to the keeping of poisons in druggists’ shops. The labelling and marking of a pot containing poison the same as another which was harmless would not be in keeping with those recommendations.

Cross-examined: The symptoms of strychnine poisoning were very well known. When he got the pot there was not more than two teaspoonfuls in it. That would be about a quarter of an ounce. The criminal officer said he got it from the Procurator Fiscal. None of it had been taken away by the Crown. He took out about 10 or 12 grains.

Counsel asked witness if he tried to find if there was anything else, and he said he wished to suggest that the stuff in the pot was a real mixture of nux vomica and taraxacum extract.

Witness said that was quite consistent with anything he said. There was no absolute taste of taraxacum. He did not try to ascertain whether there was or was not taraxacum. There was no sugar in nux vomica but there was a considerable proportion in taraxacum. The presence of a large proportion of sugar in the mixture would be strongly indicative of the presence of taraxacum. Nux vomica has a remarkably bitter taste, the most bitter that he knew of. It would be absolutely impossible for a man to take nux vomica of the size of a pea or bean and not know at once that he had taken something very extraordinary. Suppose he did take nux vomica the symptoms would appear within ten minutes of taking it, and the bolus, and then it might be twenty minutes. There was undoubtedly a difference between the viscosity of nux vomica and taraxacum.

Re-examined: The bitter taste of the strychnine would not necessarily be indicated until the strychnine were over the man’s throat, especially if he took it in a bolus.

James H. Robertson, writer, Glasgow, the deceased’s agent, gave evidence to the effect that his estate, after meeting his liabilities, amounted to nearly £900.

In cross-examination he stated that he appeared to be indebted to his firm to the amount of £8,400, but his contention was that he should get one-third share of the profits, and in that case he would have had £4,000 to the good. He also claimed that he should have had a larger share placed to his credit for wages because one of the partners had not been able to attend business. There was nothing to show that the contract of co-partnership had been altered except the conversation between parties. His claim was compromised by the deceased paying £400 into the firm.

Re-examined: The original co-partnership had expired, and the question was whether they were going
on under the original contract, or whether it had been modified. Witness was able to ascertain it from the
jottings in the hand of Mr. Lawson that he at least thought his claim was a large one, and that he was not indebted to the firm.

David A. Richmond, C.A., stated that an examination of the books of the firm of Dron and Lawson brought out that Mr. Lawson was due the firm £2486 13s. 1d. Mr. Lawson had drawn out of the firm from January, 1867, to June, 1893, averaging £291 12s. 7d. a year, besides the sum already mentioned, which was overdrawn.

Dr. Tatlock, Glasgow, city analyst, said he had analysed a portion of the substance in the pot handed over to the Procurator Fiscal. His evidence was corroborative of that given by Mr. Littlejohn.

In cross-examination, witness said he did not try to find if there was anything else in the pot than nux vomica.

This closed the evidence for the plaintiff.

Alexander Noble was the first witness for the defence. He said he was a duly qualified chemist, and was licensed by the Pharmaceutical Society of Great Britain in January, 1893. He had been in practice in the trade ten years. He was assistant to John Christie in 1893, and was now in Carlisle. He left Mr. Christie's service because he got a better salary, and he left of his own accord. He had nothing to do with the buying of drugs. He just ordered them.

The pots in Mr. Christie's shop were rarely labelled and on the top. He had no doubt that he supplied taraxacum on the morning in question. He heard nothing more about it till he heard of Mr. Lawson's death. When Dr. Christie came from the Stobcross Street shop and spoke to him about it he looked for the taraxacum, but found it still empty, while in the other pot there was a quantity of nux vomica. He found the nux vomica pot in its usual place in the cupboard with the amount of stuff there was in it now. On the label of the nux vomica there was a small mark put there by the wholesale chemist, which showed that although it was a 2-ounce pot only 1 ounce had been sent. The week before July 22nd he had taken out 133 grains to make a tincture with. That would be little more than a quarter of an ounce of aroidropus.

Cross-examined, witness said both pots were in the same cupboard but they were separated by other pots. There were partly of harmless and partly of dangerous drugs. The harmless drugs were on the bottom shelf and the poisonous drugs on the top.

Interrogated as to whether any of the recommendations of the Pharmaceutical Society as to keeping poisonous drugs were observed in this shop, witness said some of them were. In further cross-examination it appeared that the only recommendation observed was that the pots were distinctively labelled and kept separate. No taraxacum had been brought into the shop since February, 1888.

By the Lord President: He had never used taraxacum in that shop before. He had used the nux vomica frequently, and knew the pot quite well.

John Christie, the defendant, said he was a registered chemist, and had been in practice as such for ten years. He had two shops, one of which occasionally came to his shop, and used to bring bottles which had been supplied by other shops. Witness gave a statement as to the interview with David Lawson similar to that given by the latter.

In cross-examination he stated that within the last four months he had kept all poisons in his shop on a different principle than before that time. On being pressed, witness admitted that he had disregarded the recommendations of the Pharmaceutical Society, but said they had to fit up their premises to suit their business.

Dr. Christie, son of the previous witness, also gave evidence.

John Clarke, public analyst for the city of Glasgow, said he analysed a portion of the drug in the pot handed by Dr. Brown to the police. He found in that at the bottom 5 per cent. of strychnine or other alkaloid, and 4 per cent. in that on the sides of the pot. In pure extract of nux vomica there was 15 per cent. of strychnine. From that he drew the conclusion that this was not pure nux vomica. He would say there was two-thirds of taraxacum and one-third of nux vomica in the pot. The test that could be applied was by adding bicitarcoante of soda. Bicarbonate of soda added to nux vomica made no difference, but added to taraxacum it changed the colour. The large proportion of sugar he found would be accounted for by the presence of the taraxacum. There was a difference in the viscosity of the two drugs. If the deceased drew off nux vomica from a knife with his teeth it would stick to his teeth, and the bitter taste of the nux vomica would be felt.

Cross-examined: 15 per cent., was laid down by the Pharmacopoeia as the Midland strength of nux vomica. It was an arbitrary rule. Witness did not suppose the deceased could have rolled the nux vomica into a bolus and swallowed it. It was so sticky that he would have to roll it with flour.

Mr. Nisbet, one of the examiners to the Pharmaceutical Society, who conducted the analysis along with Mr. Clarke, concurred in his evidence.

Malcolm Kerr, assistant in a chemist's shop in Dockhead Street, Saltcoats, said he sold 2d. worth of taraxacum to David Lawson on the day of Mr. Lawson's death. Although that was the only time he had seen David till that day, he was quite certain it was he that sold the drug to. He had never seen John Lawson before.

William Dron, engineer, said he was now sole partner of the firm of Dron and Lawson, engineers, Glasgow. He had frequently had to speak to David Lawson about overdrawing his share in the profits of the business, and told him he would have to put some more money into the business or operate the steps in the matter. When Mr. Lawson died he was put 23rd to the firm. Witness spoke to Mr. Lawson about overdrawing his share he never suggested that he was mistaken. He admitted it, and said if things were squared he would have nothing. He never suggested that he had more than a fourth interest in the firm. He never came to witness and had a third share. Witness accepted £3000 because he could get no more. The bank held securities, and he could not get possession of them.

Cross-examined: He was not aware that his family got some £200 after everything was paid. It was surprising to him to hear that.

This closed the case, and Counsel then addressed the jury.

Judgment.

The Lord President, who was the presiding judge, in charging the jury said the case was not a plain sailing one, but required careful attention. Each of the pursuers was entitled to a question of fact was whether the deceased was the husband and father, if the defender was liable, but he questioned if they had lost so much by way of money as one might be led to suppose. The defender's counsel had indicated his willingness to take it if nux vomica was sold by Mr. Christie, he would be liable. But the chief question of fact was how the pursers had made out that the staff which Mr. Lawson took and died of was sold by Noble, the defendant's assistant. The burden of proof was
on the plaintiffs, and it was for them to make out their case and remove from the minds of the jury reasonable doubt as to the cause of death. He pointed out that Mr. Lawson did not immediately on purchasing the drug partake and die of it. The stuff was purchased on May 28, and death took place on July 14. The pursuer's case was that pure nux vomica had been supplied to the Lordship. His Lordship further pointed out that apparently the suspicions of the family did not at once fall on the taraxacum, because when the doctors asked if Mr. Lawson had had any medicine, it was only after some delay that they mentioned the taraxacum. Mr. Lawson's conduct at the time of his death would certainly lead to the belief, so far as the evidence went, that he had a good conscience, and his belief was that death was caused by Christie's stuff. It was a great pity that that part of the plaintiff's case was not corroborated rather than slightly contradicted. His Lordship reminded the jury that there was evidence that a fresh supply of the stuff was brought into the house on the day Mr. Lawson died, and concluded by saying that if the jury thought they had not got to the bottom of the case, if they thought that reasonable loopholes were open for the supposition that other drugs were put into the jar for the man's use, then he did not see how they could find a verdict for the plaintiff.

The jury retired, and, after being absent for fifteen minutes, returned with a unanimous verdict for the defendant. They were of opinion that the plaintiffs had failed to prove their case.

Counsel for the plaintiffs, Mr. Comrie Thomson and Mr. W. Campbell. Agents, J. and J. Galloway, B.S.C.

Counsel for the defendant, Mr. Graham Murray, Q.C., and Mr. Salvesen. Agent, F.J. Martin, W.S.

POISONING CASES AND INQUIRITS.

DEATH FROM ALKALINE POISONING.

Charles Cecil Jenner died at Brighton on Wednesday, December 19, from the effects of poisoning by an alkali. Verdict: "Poison was self-administered during temporary insanity."—Morning Leader.

AN OVERTOXIC OF LAUDANUM.

Mrs. Stewart, aged 70, was found dead in a bedroom in her house in English Street, Dumfries, last week, death being due to the effects of an overdose of laudanum.

—North British Daily Mail.

POISONING BY SULPHURIC ACID.

Patrick O'Connell, aged 3, died on Wednesday, December 19, at Ranelagh, from the effects of sulphuric acid, which he got hold of while straying through the washhouse or bottle stores of a public-house. Verdict: "Death from sulphuric acid poisoning."—Irish Independent.

POISONING BY MORPHINE.

Augusta Gouet, aged 40, died at Kentish Town on Thursday, December 18, as the result of blood poisoning, due to deceased's habit of injecting morphine into her arms. Verdict: "Death from blood poisoning, supervening upon the abscusses caused by the continuous injection of morphine."—Morning Advertiser.

POISONING BY CARBOLIC ACID.

Mrs. Cruikshank, aged 34, died at 104, Kennington Road, on Wednesday, December 19, from the effects of carbolic acid, self-administered. Verdict: "Temporary insanity."—Star.

Correspondence.

TINNY. MYRHER, B.P.

Sir,—In answer to Mr. A. McKeffer (Pharm. Journ., Dec. 1, p. 489), I may say that my experience has been that once myrrh cannot very well be prepared "by percolation without previous maceration." That is, I do not condemn percolation, but, instead of damping the myrrh, as I should certain other things, in the ordinary way, with a small amount of the menstruum, I should prefer to macerate in a distinct bulk, so as to dissolve out the soluble matter. I should then pour into a percolator, allow to drain, and finally wash out with more spirit. Damping the myrrh with only a small amount of spirit gives a tenacious mass, difficult to pack, and difficult to percolate. And putting dry, coarsely powdered gum into a percolator does not answer very well either, since spirit poured on never completely displaces the air. The soluble portions are readily forced downwards, but, from its viscid nature, the lower layer is not easily removed. Free channels through the more exhausted portions are formed, and the menstruum has a tendency to pass through them, since they offer less resistance.

H. W. JONES.

Coventry.

MEDICAL MEN AND MANUFACTURERS.

Sir,—Not long ago I happened to call at one of our leading houses, and while waiting overheard a conversation between one of the assistants and a customer who wished to purchase a bottle of Parrish's Food. Question after question was asked and replied to with intelligence and in perfect good faith, but when at last the customer left the shop, knowing almost as much about the syrup as Professor Parrish could have told him, there was still a lurking misgiving about his manner which intimated that after all he was afraid he had been sold. I ventured to say that, though I was pretty used to this sort of scepticism myself, I was, nevertheless, surprised to meet with it in an establishment of such note. Said the assistant, "The British public just now welcome a falsehood; tell them the plain straightforward truth and they disbelieve you, tell them a big thumping lie, and the bigger it is the more readily they swallow and like it." Now it is quite easy to understand how the ignorant who believe all they see in print to be gospel may buy a box of pills because a glaring yellow board informs them it will cure all ailments, or a cough cure because their letter-boxes have been stuffed with testimonials, but what are we to say when men who have received a scientific training prove as credulous as the habitual swallowers of so-called patent medicines. Dr. Notas indignantly appeals to the Pharmaceutical Journal against a system which we chemists know to be supported by, I think I am warranted in saying, a majority of his confrères. Day after day are we sending all over the town for preparations ordered in prescriptions, preparations we often obtain with considerable trouble and expense, and which we know will never again be required. Ephemerical pharmacy is not a source of profit or pleasure to us, and we in our turn appeal to the medical profession to discourage by all means in their power a practice which cannot enhance their reputation. "Some people," said James Hinton, "can't see beyond their own noses." Is it not obvious that when these remedies have been introduced to patients they will speedily desert their friends' guiness by recommending them in their turn? And, finally, the makers will only need to publish popular works on medicine, drawing attention to the value
of their goods as remedies, much in the same manner as our homoeopathic friends have already done, to still further affect the incomes of the very gentlemen who so rashly advertised them in the first instance. But I have little faith in appealing to future benefits; the defect which has rendered the practice possible is obvious, and arises from the defective training of the medical student. The old apothecary had at least a practical knowledge of pharmacy, and if drugs are of value, the medical training of to-day should include a thorough and practical knowledge, not only of drugs in general, but also of the varied preparations which are official and those which are in common use. In no other way will he be able to avoid the reproach that he is engaged "in pouring medicines of which he knows little into bodies of which he knows less"; in no other way will he be able to demonstrate that the noble profession of medicine rests on a firm basis, the basis of scientific knowledge.

PHARMACOS.

Sirs,—Having noticed an article in the Journal by J. G. Notus, M.D., re "medical men and manufacturers," I should like to express a few words on the subject. Would that all medical men entertained the same antipathy towards those so-called "specific nostrums," but, alas! the call for them is daily increasing, as if the medical man was unable to prescribe such a wonderful combination, or double the ability of the qualified chemist. So long as medical men prescribe, or rather administer these bogus remedies, chemists are powerless to stop the sale of them, and they will daily increase in the market to the detriment of the patient, the doctor, and the chemist alike. But, unfortunately, medical men do not stop here, but order So-and-so's pills, So-and-so's poppin. liquid, etc., to the annoyance of the chemist, who surely is conscious enough to manufacture as good an article at a more reasonable price for the patient. The extra time occupied in writing a proper prescription with suitable doses will surely repay the busy medical man in the end. Very often, too, the chemist is considerably out of pocket in getting these preparations; hence we have dozens of them put aside so as not to vex the eye. A portion of a small bottle is ordered, and this is never wanted again—why? because the contents are not efficacious! The preparations live a short life, and die out altogether.

"FREETHINKER."

Answer to Correspondent, etc.

T. Dunlop.—You are not likely to find any record of such change, which exists only in the imagination of the manufacturer. You may therefore continue to rely upon the B.P. text with perfect confidence.

Nefis, etc., received.

Notices to Contributors.

** Advertisements must be sent to Street Bros., 5, Serlo Street, Lincoln's Inn, W.C., and instructions respecting the transmission of the Journal to the Secretary—Mr. Richard Breindrig—17, Bloomsbury Square, W.C.; premature delay may be caused.

Communications should reach the Editorial Department, 17, Bloomsbury Square, W.C., not later than the first post on Wednesday, if publication be desired in the next issue of the Journal; though prompt publication cannot always be guaranteed.

Matter intended for publication must be written in ink, on one side of the paper only, and be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.

No notice can be taken of anonymous communications, and contributors are requested, as far as possible, to append their proper signature rather than pseudonym, a greater value being thus given to any opinions expressed.

When illustrations are necessary, pen and ink drawings, consisting entirely of clean and sharp lines—and, preferably, twice the required size—must be supplied not later than a week before the proposed date of publication.

Before entering upon a retrospect of the pharmaceutical events of the past year, it will be useful to recall to mind the fact that, during the interval which has elapsed since the celebration of the Society's Jubilee, very important changes have taken place in the views entertained as to the Pharmacy Act, 1868, and its applicability for the purposes it was intended to serve. In consequence of judicial interpretations which some provisions of the Act have lately received, the need of amendment—once generally recognised—has been to a great extent done away with. Thus the effect of the decision in the Wheelon case has been to give greater importance to legal qualification under the Act, both as a matter of public policy and as a means of protecting the interests of chemists and druggists. In like manner the more recent interpretation of the provisions relating to the sale of poisons has now given them an application without which the Act would have no rational significance for the public or for pharmacy. The satisfaction to be derived from these circumstances is only mitigated by regret that they have not been brought about more largely by the initiative action of chemists and druggists, instead of being, to a great extent, the result of action taken by the Treasury in the first instance, and subsequently of outside pressure from coroners and the medical profession.

During the past year still further advance has been made in the same direction, though opposition—either active or passive—has been encountered even from within the ranks of chemists and druggists, the Pharmaceutical Society being meanwhile regarded by three-fourths of those engaged in the trade as their natural enemy because of its power to enforce the Pharmacy Act.

In reviewing the progress of pharmaceutical affairs, it is, however, interesting to observe from year to year, indications of a growing tendency, among chemists and druggists, to revert to the views held by the founders of the Pharmaceutical Society, and by its earlier promoters, in regard to the main objects with which the Society was established. The necessity for qualification upon a sound educational basis, not only in the interest of the general public, but also as the means by which the material interests of chemists and druggists may be most effectually protected, is beginning to be more fully and more generally recognised. Comprehensive organisation and united effort have at least been recognised as needful for giving effect to that fundamental principle. But, side by side with the development of these opinions, antagonistic influences have also come into existence. The necessity for proprietary qualification—held by the founders of the Society to be a condition essential for protecting the general interests of pharmacy—was practically sacrificed in 1868 by adopting, as the legal standard of qualification, the lower grade originally intended only for assistants. Opportunity was thus afforded for limited companies of unregistered persons to carry on the business. But the present sense of the injustice of that practice may be attributed to a conviction that the personal qualification of proprietors is a condition as indispensable for the due protection of chemists and druggists and of their interests, as the qualification of persons selling or dispensing poisons is from the point of view of public policy. The two requirements are, in fact, inseparable, except from a one-sided point of view, and such a mode of regarding the matter can only tend to the disadvantage of chemists and druggists.

Under existing conditions—while the legal definition of pharmacy is limited to the sale and dispensing of scheduled poisons, and while personal qualification of the actual seller or dispenser continues to be the only legal requirement,—the endeavour to give full effect to the provisions of the Pharmacy Act, 1868, is the only means by which the interests of the trade can be conserved. The work done in that direction by the Society during the past year has been productive of good results by the further settlement of questions relating to the application of the Act. One of the most important cases was the prosecution of a grocer in the Derby County Court for the sale of Powell's balsam of aniseed, a preparation containing, in one fluid ounce, one-tenth of a grain of morphia. The decision given by his Honour Judge Kemble Digby, was in favour of the Society, and in accordance
with the evidence produced on both sides, after
long consideration, in which the devices of forensic
sophistry failed to impress the judge in a contrary
direction. Following the precedent already estab-
lished in the _Piper_ case, the judgment declared
that the sale of the preparation in question by an
unregistered person, was not protected by the
principle de minimis non curat lex, but was an
offence within the Act.

This decision was appealed against in April in the
Queen's Bench Divisional Court. After hearing the
arguments of counsel for the appellants, and with-
out calling upon counsel for the Society to reply,
Justices _Charles_ and _Bruce_ confirmed the deci-
sion of Judge _Kennel Diogy_, as their only possible
alternative. They also remarked that the question
as to the poisonous nature of a preparation is un-
affected by directions given to the purchaser as
to doses, and that restraining incompetent persons
from dealing in poisons is of much more im-
portance than any inconvenience arising from
restricting the sale of proprietary medicines.

A further appeal from that decision was heard
before the Master of the Rolls and Lords _Justices Kay_
and _A. L. Smith_ in July, with the result that, after
long arguments on behalf of the appellants, the
appeal was again dismissed, with costs. In the course
of this case it was argued that a preparation in
which the amount of poison was infinitesimal would
not come within the scope of the Act. This argument
elicited from Lord _Esher_ the remark that the
Courts ought not to enter into the question of
quantity, and that if there were any of the prohibited
things at all in a preparation, it should not be sold
by unqualified persons. In his judgment, also, he
referred to the "infinitesimal argument," and de-
dined the word infinitesimal as relating to a thing
so small that the Courts would treat it as not exist-
ing at all. These judgments in the superior Courts
have now effectually disposed of the question as to the
applicability of the term "patent medicine" to articles
which are not the subject of Letters Patent. They
have also decided that the object of the Act was to
prevent the sale of poisons by any but legally
qualified persons—that poison mixed with other
ingredients is still poison within the meaning of the
Act—and that the principle de minimis non curat lex
would apply only in cases where the Court could
decide that a poison was not present.

Another case of prominent importance was the
appeal against the decision in one of a series of prose-
cutions instituted in November, 1893, against un-
registered persons acting as assistants in chemists' shope kept by medical men in Glasgow. These cases
were decided in favour of the Society; but they were
not mentioned in the retrospect of 1893, because a
medical association in Glasgow had announced its
intention of contesting the decisions, and the matter
was to some extent sub judice. The appeal was
heard in the High Court of Justiciary, in Edin-
burgh, at two long sittings in the month of March,
and in June judgment was given in favour of the
Society.

The decision of the questions of law raised in this
appeal was to the effect that while the holder of a
medical qualification is exempt from the first fifteen
sections of the Pharmacy Act, and can keep open
shop or sell and compound poisons, that exemption
does not extend to unqualified persons in his employ.
It was thus shown that the Act applies to chemists' shops kept by medical men in the same way that it
was shown by the _Wheelton_ case to apply to shops kept by registered chemists.

The proceedings already mentioned, though of neces-
sity instituted by the Society as the body empowered
to take such action, have been undertaken, not merely
on behalf of its members, but primarily in discharge
of the public duty imposed upon the Society by the
Pharmacy Act for the benefit of the community.
That is the point of view from which the judicial de-
cisions affecting the interpretation of the Act have
been arrived at, and any advantage or disadvantage
accruing to chemists and druggists, either directly or
indirectly, has been a matter of secondary considera-
tion. But in addition to the public service rendered
by enforcing the provisions of the Pharmacy Act in
regard to the sale of poisons, the members of the
Society have been benefited by the correct inter-
pretation of the Act, and with them all persons
entitled to carry on the business of chemists and
 druggists have been equally benefited by the
suppression of illegal practices.

**PATENT MEDICINES.**

The difficulty that has arisen in
regard to patent medicines—partly
from the exemption relating to
them in section 16 of the Pharmacy Act, 1888, and
partly from the loose popular application of the
term "patent medicine" to articles which are not
patented, being improperly associated with the
terms of that section,—has now [been to a great
extent removed by the decisions as to the mean-
ing of the term "patent medicines." But a
further question has been raised by the attempt to
secure immunity from the Pharmacy Act by patent-
ing medicines containing scheduled poisons. If
that proceeding were admissible, the facility
afforded by the patent laws for obtaining patents
would be an easy means of evading the law relating
to the sale of poisons. The Council has there-
fore had to deal with this matter as mentioned in
the Annual Report, and practically the prin-
ciple has been established that the patenting of
a medicine containing a scheduled poison would
be contrary to public policy. On that ground the
action taken in 1893 has been continued, and
further applications have been made to the Court of
Chancery for the revocation of several patents.
recently granted for such medicines. Those applications have been successful; but since the patentees have again in each case consented to revocation of the patents in question, the decisions of the Court do not amount to an authoritative legal precedent, or finally dispose of the question as to the proper construction of the Act in this respect. From the revocation of these patents, it may, however, be inferred that, since the passing of the Pharmacy Act, the grant of Letters Patent for medicines containing scheduled poisons has been absolutely barred. That inference is supported by consideration of the provisions of the Pharmacy Act relating to the sale of poisons and to the exemption of patent medicines from those provisions. It is supported still more strongly by the proviso, contained in all Letters Patent, that they are ab initio void if they relate to anything contrary to law, or prejudicial to Her Majesty's subjects.

By these proceedings, therefore, substantial progress has been made towards securing an interpretation of the Act that would, consistently with its general object, prevent its provisions from being evaded under the apparent sanction of Royal Letters Patent. The applicability of the Act to medicines which were actually the subject of valid patents at the passing of the Pharmacy Act, would appear, from a common-sense point of view, to be equally clear; for all such patents have now expired, as well as the right to any privileges they conferred, including that of exemption from the provisions of the Pharmacy Act. In fact, the object of that exemption can only be regarded as that of affording just consideration for privileges which had been acquired previously, and were in existence for the duration of the patents then in force. In that sense, therefore, the exemption of patent medicines in section 16 of the Pharmacy Act has, in fact, now become practically obsolete and ineffective for any other purpose than that of demonstrating the present incompatibility of the statute law with the grant of a patent for medicine containing a scheduled poison.

However, systematic investigation of the applications for patents relating to medicinal preparations has now become necessary for the purposes of the Pharmacy Act, and in addition to the duty devolving upon the Registrar in regard to ordinary cases of infringement of the law, he has now to scrutinize the work of Her Majesty's Patent Office in order to prevent evasion of the Act by that means. Up to the present time no less than 109 applications for patents for medicines have been investigated with that object. Of these 17 have been abandoned by the applicants on being apprised of the intention of the Council to oppose, in 54 instances the specifications did not disclose anything contrary to public policy, 22 cases are still being watched in their progress, and, in 6 instances where patents were actually granted, applications for their revocation have been successful on the ground that the patentees would have been conducive to infringement of the law in regard to the sale of poisons.

ADMINISTRATION Throughout the year the General Purposes Committee of the Pharmacy Act. Council has been engaged in the consideration of some 400 cases in which infringements of the Act have been reported. As a consequence, a very large number of prosecutions have been instituted, and the monthly reports presented by the Society's solicitors have shown that in most instances the penalties incurred have been paid without trial. In several cases that has not been done until the last moment, when all provisions for the hearing in court had been completed; and the expenses so incurred have been considerably in excess of the penalties paid. The administration of the Act by the Council on behalf of the Society, being, however, in the main a public function which must be exercised when the facts of a case show that action is requisite, the attendant expenditure is a contingency which must be provided for from the private funds of the Society. Action so taken to enforce the law is not only of direct benefit to the public, but is also indirectly beneficial to the entire body of registered chemists, whether connected with the Society or not. Three-fourths of the chemists actually in business on their own account participate in the benefits derived from the administration of the Act without contributing to the Society either financial or moral support.

EXAMINATIONS One of the most important parts of the public work carried on by the Society is the conduct of the examination required by the Act for admission to the Register of Chemists and Druggists. Various improvements which have recently been adopted, partly at the suggestion of the late Government visitor, have already increased the efficiency of this examination, a result which is of less importance for safeguarding the interests of chemists and druggists than it is for the protection of the public. Similar improvements have also been introduced into the voluntary examination for admission to the ranks of pharmaceutical chemists.

According to the report presented to the Council by the Registrar in February, the total number of candidates for the Minor and Modified examinations in England, Wales, and Scotland, during the year 1893, was 1198; the percentage passed, 39-39. The number of candidates for the Major was 152; the percentage passed, 45-39.

The report presented to the Privy Council for the year ending in March, 1894, by Dr. Strevens, as Government Visitor of the statutory examinations conducted by the London Board
of Examiners, was laid before the Council at the meeting in April. Generally, the report stated that year by year steady progress is being made towards the desirable result of securing, with advantage to the public, more chemists and druggists having scientific and practical knowledge.

So far as public interests are concerned that report was as satisfactory as previous reports have been. But in regard to the present condition of pharmaceutical education, the reference to details is less satisfactory. In speaking of the elementary, First examination and of the "lamentable deficiencies" of those presenting themselves for it, to which attention had been directed in previous reports, satisfaction was expressed that while the proportion of candidates who passed had increased from 47·6 to 51·4 per cent., the number of failures in arithmetic had also diminished one-third.

The results of the examination for qualifying as a registered chemist and druggist were reported to be practically unchanged in regard to the proportion of passes (34 per cent.), and from careful inquiry into the numerous instances of deficiency in chemistry and practical laboratory work, they were found to be the result of defective training.

In the Major examination the percentage of passes (46·4) was reported as showing an increase of seven per cent. over the previous year, but without sacrifice of thoroughness in the examination. Here again, however, deficiency in chemistry and physics was the chief cause of failure.

According to the report of the Executive of the North British Branch of the Society, the proportion of passes in the Minor examination at Edinburgh, during the year ending in March, 1894, was 40·25 per cent., and in the Major examination it was 30·77.

The result of the Minor examination generally during the whole of the past year has been but little different, the proportion of passes being 37·13. It follows, therefore, that even if the stringency of the examination has increased, as well as its efficiency for the purposes of the Act, the candidates have either been better prepared or they have had a better opportunity, under the new regulations, of showing their fitness to be placed on the Register of qualified chemists and druggists.

In the Major examination a similar result has been shown, the percentage of passes being 50·34. In both cases, therefore, the change appears to have been distinctly to the advantage of the candidates, though, at the same time, the defects of pharmaceutical education are proved by the very large proportion of failures in both examinations.

The result of the First or Preliminary examination still continues to point to the existence of very unsatisfactory conditions. The number of candidates during the year 1893 was 1489; the percentage passed, 49·63. During the past year there have been 1541 candidates, and the percentage passed was 48·88. If the proportion of failures in this examination applied to youths about to enter the business as apprentices, the result might be regarded as satisfactory, in so far as it showed that undesirable persons were prevented from entering the business. But that is not the case. The persons who fail in this preliminary examination are, for the most part approaching, and sometimes beyond, mature age; they have already been engaged in the business for several years, and the present defective position in regard to this examination, provides a back door by which entry to the business is unduly facilitated to the incalculable detriment of registered persons.

From the report presented to the Council by the Registrar in February, showing the condition of the Registers of chemists and druggists, and of pharmaceutical chemists, as well as the strength of the Society for the year 1893, it appeared that the additions to the Register of Chemists and Druggists during the year were 497, while the deaths and erasures were together 219, showing an increase of 278 registered persons. At the end of the year the number of names on the Register was 14,798. Out of the whole number 2286 were pharmaceutical chemists; 2250 were members of the Society, 2562 associates, and 811 students. One consequence of making the Minor qualification the basis of registration under the Act of 1868, has been a rapid increase in the number of associates of the Society. By that means the existence of the class of chemist and druggist members has been practically revived and continued instead of being gradually superseded by pharmaceutical chemists, as originally intended, and as was desired and anticipated even in 1868. The number of associates has now become considerably larger than that of members, but they are not eligible as members of Council, and it has long been thought that under existing conditions they should be placed on the same footing as chemist and druggist members. Assuming that out of the whole number of persons unconnected with the Society some 4000 were in business before 1868, there must be more than 5000 registered since then who have not joined the Society. This abstention is perhaps partly due to the disability attaching to associates, and, from the point of view of trade federation, it has become evident that all persons possessing legal qualification should be entitled to stand upon an equal footing in regard to their connection with the Society. This, however, is a matter affecting the constitution of the Society, and the action taken in regard to it is referred to in another part of this article.
Besides the transaction of usual routine business, the Council has been occupied during the year with various matters of special importance. At the January meeting the presentation of a jury, communicated by the coroner at Ipswich, to the effect that white precipitate should be included in the first part of the poisons schedule, was considered, and it was decided not to be desirable. Communications from the Privy Council relating to the use of specially shaped bottles for poisons, the sale of vermin killers at oil shops, and of other poisons by photographic dealers, were considered at the February meeting, and replies were sent stating that provision is made for dealing with infringement of the Act in these respects, but that specially shaped bottles were not considered likely to effect the object desired.

At the meeting in March it was decided not to attempt the formulating of a code of ethics in accordance with the suggestion submitted to the Council by the Chemists' Assistants' Association. The objection to the proposed code of ethics was mainly based upon the difficulty of exercising the power to strike a person off a register on which it is legally necessary for the practice of his calling that his name should appear. That has been shown by the proceedings under the Medical Act, and the difference in the case of solicitors is to be ascribed to the fact that it is out of regard for damage to the public a solicitor is struck off the Rolls, and not on account of improper conduct damaging only to members of his own calling. If the right to practise a calling be not affected by exclusion from an official register, the controlling influence of the power to exclude will not be of much account, unless there be a strong bond of union among the members of that calling, and the moral force of public opinion among its members is equally potent. Where those conditions exist, as at the Bar, they supersede the necessity for power to strike off a register.

Another subject discussed by the Council was the system of awarding school class prizes which had been suggested by Mr. Schacht with the object of assimilating the practice of the Society to that adopted by universities and colleges, of classifying students according to the character of their work instead of giving a number of prizes which might all fall into the hands of one or two conspicuous individuals. The chief objection to Mr. Schacht's proposal was based on the fact that entry for the examinations is optional, and that the Society's School does not yet, in regard to its examinations, resemble a university in granting, on the basis of a curriculum, degrees for obtaining which examination is a necessity. Considerable sympathy with the idea of Mr. Schacht's scheme was expressed by several members of Council, and, while its impracticability under existing conditions was recognised with regret, hopes were expressed that, under suitable conditions, such a system might eventually be adopted.

At the same meeting it was decided, on the recommendation of the School Committee, that students connected with the Society should be permitted to compete more than once for any one of the prizes offered at the end of each course of instruction attended by them in the School, but that no student should be permitted to take the prize in any class more than once. This reversion to a previous condition of things was adopted as the result of continued effort on the part of Mr. Allen, his object being to remove any obstacle to attendance at the classes, and to increase the inducements for apprentices to enter the School.

Another important item of the business transacted at the April meeting of the Council was the discussion and ultimate adoption of a draft Bill for the amendment of the Pharmacy Acts. Its chief object was to render every registered chemist and druggist eligible as a member of the Society, and to modify the provisions of the Society's Charter as to the mode in which members of the Council retire from office annually. In restricting the Bill to these constitutional alterations, requisite under existing conditions for the consolidation of the Society, the object was to eliminate any possibility of opposition arising, either from differences of opinion among chemists, or from apprehension of interference with public interests.

At the first Council meeting in May a resolution passed by the Western Chemists' Association of London was presented, expressing general approval of the draft Bill, but suggesting that the proposed limitation of the number of members of the Council, not on the Register of Pharmaceutical Chemists, was undesirable, as being likely to affect injuriously that unity which is so essential. This communication was referred to the Law and Parliamentary Committee for consideration. Mr. R. A. Robinson, subsequently gave notice that he would bring forward a motion on the subject at the annual meeting of the Society, and it then gave rise to a long and animated discussion. At this meeting of the Council, Sir Frederick Abel, Bart., Professor Sidney Ringer and Professor Reimington were elected honorary members of the Society. Dr. George Watt, of Calcutta, and Professor Rusby, of New York, were also elected corresponding members.

At the Council meeting in April it had been reported that out of seventeen persons nominated as members of the new Council, sixteen had signified their willingness to accept office. The new candidates were Mr. Batson, of Kendall, Mr. Campkin, of Cambridge, and Mr. Gostling of Dijss. At the election in May thirteen of the members of Council who had retired were re-elected, and the
vacancy created by Mr. Marshall Leigh not offering himself for re-election, was filled by the election of Mr. Gostling.

At the first meeting of the new Council in June Mr. Cartwright was again re-elected President—a tribute to the conspicuous ability and zeal evinced during a succession of years in directing the onerous work of the Society. Mr. Cross was re-elected as Vice-President, and Mr. Hampson as Treasurer, Mr. Richard Berriedale being reappointed Secretary and Registrar. On the recommendation of the General Purposes Committee it was decided not to make an official representation to the Government in regard to the subject of the increased duty on spirits, upon which communications had been received from the chemists of Burley and from Mr. Carlton of Peterborough. A report of a General Purposes Sub-Committee on the method of conducting the Society’s examinations as compared with the methods adopted by other bodies was presented, with recommendations as to various rearrangements of details, and the appointment of examiners engaged in teaching chemistry and botany. After a long discussion the changes recommended were adopted, and it was resolved that they should come into operation at the end of the year.

At the meeting in July a motion was brought forward by Mr. Martindale in reference to the use of metric weights and measures, suggesting that after January, 1895, practical knowledge of the metric system should be required in the subjects of prescriptions and dispensing in the Minor examination. In the discussion of this subject considerable difference of opinion was evinced, and it was eventually resolved that the Boards of Examiners should be requested to consider the desirability of adopting Mr. Martindale’s proposal.

At the next meeting of Council, in August, the President reported that the Boards of Examiners did not consider that, in addition to the practical acquaintance with the metric system already required in the chemical part of the Minor examination, further practical examination in dosing by or dispensing by that system was desirable at present, and a resolution was passed to that effect.

The special business before the Council at the meetings in October and November, has been dealt with in other parts of this article. At the December meeting a suggestion made by the Chemists Assistants’ Association as to the provision of postgraduate courses of lectures and laboratory demonstrations, was brought forward, and on the recommendation of the Committee, by which it had been considered, it was decided that the scheme suggested could not be adopted, though the Council would be willing to assist in promoting higher education if a desire were expressed on the part of a sufficient number of pharmaceutical chemists. The recommendations of the General Purposes Committee and of the Executive of the North British Branch, in regard to the appointment of examiners for the ensuing year, gave rise to a long discussion chiefly in reference to a possible doubt as to the advisability of appointing to that office professors connected with the Society’s School, all the members of Council being agreed on the principle of appointing teachers as examiners, and as to the fitness of those who had been nominated by the Committee. Eventually the recommendations were adopted, and the appointments were made.

The Scottish Executive and the British Board of Examiners for Scotland Branch have continued their work in promoting the objects of the Society, and the Chairman of the Executive, Mr. Laidlaw Ewing—re-elected to that position last July—has been actively engaged during the year in superintending the construction of the Society’s new premises in Edinburgh, the official opening of which by the President was celebrated at the end of October by a conversation. On that occasion the members of Council accompanying the President and the Secretary were entertained at a dinner, given by Scottish pharmacists, at which many distinguished persons were present, and highly complimentary opinions were expressed as to the beneficial influence of the Society’s labours to advance pharmacy and promote the interests of those engaged in the calling.

The Annual Meeting. The discussion of chief importance on this occasion was in reference to the proposal to abolish the distinction between pharmaceutical chemist members of the Society and chemist and druggist members, in regard to eligibility to serve on the Council—a motion to that effect being brought forward by Mr. Robinson, and seconded by Mr. Urwick. The argument used by both was that in regard to the constitution of the Society as a representative body, the legal position of pharmaceutical chemists had been so altered by the Act of 1868, that the reason for their preponderating representation on the Council has ceased to exist. The discussion on both sides was, however, more largely influenced by sentimental considerations than by regard for that indisputable fact. That was the case with the argument in favour of equality, no less than with that as to the prerogative of pharmaceutical chemists. The tenancy is towards the Society being chiefly constituted of chemist and druggist members; but its obligations under the Charter and the subsequent Acts, would not thereby become any less than if it were mainly composed of pharmaceutical chemists. The promotion of education, as well as the advance-
ment of chemistry and pharmacy, must always remain among its chief objects. Desirable as it is to protect to the utmost the rank of pharmaceutical chemists, it is probable that from the nature of things, and under the influence of various accidental conditions, they will continue to form a sort of inner circle within the larger community to which they belong. As suggested by Mr. Exin the voting at the annual meeting cannot, however, be regarded as deciding a question of so much importance.

The other proceedings at the annual meeting of the Society in May were not marked by any unusual feature. In moving the adoption of the Council report the President described the litigation then in progress with regard to the interpretation of the Pharmacy Act, and discussed at length the various points which had been raised in connection with the sale of poisons. The subsequent discussion related mainly to the question whether the application of the Act to medicines containing scheduled poisons is limited by regard to the quantity of poison in them. Mr. Lomas supported the view that if a poison were present, in any amount whatever, the preparation containing it would come within the scope of the Act. Mr. Atkinson, on the contrary, evidently impressed by the consideration of quantity which has so unnecessarily complicated the cases brought before the Courts, was disposed to censure the Council for having in the Delve case relied upon the mere presence of morphine in licorice as being sufficient, without proving the quantity present or the poisonous nature of the preparation. In doing so, he relied upon the judgment in the Armson case, in which Judge Kemmel Digby stated that he decided in favour of the Society, because the medical evidence given satisfied him there was a sufficient quantity of a scheduled poison in the bottle of balsam of aniseed to be fatal. But, while perceiving that the medical evidence had in that case assisted the decision of the judge, Mr. Atkinson suggested that the importance of medical evidence was a mistake, because it might give rise to a conflict of opinion between rival posologists. The decision of Lord Esher on the point of infinitesimal quantity had not then been given, and Mr. Atkinson’s argument involved the fallacy of assuming, as Judge Helywood had done in the Delve case, that evidence of quantity is necessary for proving possible poisonous effect and bringing a preparation within the scope of the Act. That fallacy was pointed out by Mr. Flux, who also showed that the Act entirely eliminates the necessity of proving either quantity or poisonous effect, by declaring that certain articles—to be sold only by registered persons—shall be deemed poisons within the meaning of the Act. The decision of Judge Helywood in the Delve case was based solely upon the fact that the quantity of morphine was not proved, and it involved the erroneous assumption that evidence as to quantity is necessary for proving the preparation in question to be poison within the meaning of the Act. The appeal against his judgment could not be heard, because he had found upon the question of fact, though it was not in reality material to the case brought before him.

In regard to the non-enforcement of the Pharmacy Act in the past, Mr. Atkinson expressed the opinion that the Council was responsible for ignoring and neglecting the powers conferred by the Act. He appeared, however, to overlook the fact that these powers are not conferred upon the Council, but upon the Society, and that while the Council, as its elected executive, has theoretically unlimited power of action in the exercise of State functions entrusted to the Society, its action in a representative capacity must necessarily be influenced by the prevailing views of the body it represents. In abstaining from such procedure under the Act as has recently had the effect of giving to the law increased significance, the Council has represented the general feeling of the Society and of the trade. Mistaken as we now know that feeling to have been, any reproach it merits does not lie against the Council, but against the Society and the trade. The invasion of the rights of chemists and druggists, which is now a ground of general complaint, has been a consequence of the too general reluctance to conform to the law and to seek protection by enforcing its provisions.

The Library in London has been fairly well attended during the year, of the Society. The number of readers being only slightly below that of the preceding year. Most of the readers are students in the Society’s School and in other schools of pharmacy in London, although members and associates also make occasional visits for purposes of reference. The number of books lent out has increased considerably, country borrowers taking a large proportion. About 250 volumes have been added to the Library, partly by purchase and largely through donations. These comprise medical and scientific periodicals, which are received regularly as published, and standard books, amongst which may be specified Quain’s ‘Dictionary of Medicine,’ Gould’s ‘Medical Dictionary,’ Chambers’ ‘Encyclopedia,’ the concluding volume of Watts’ ‘Dictionary of Chemistry,’ Kerner and Oliver’s ‘Natural History of Plants,’ Frankland’s ‘Micro-Organisms in Water,’ Crookes’ ‘Select Methods in Chemical Analysis,’ the ‘National Dispensatory,’ the ‘Dispensatory of the United States,’ a considerable selection from the library of the late Emeritus Professor Bentley, and other works. A new bookcase has been erected to meet the continually increasing demand for additional
space. In September the Librarian attended the annual meeting of the Library Association of the United Kingdom, held in Belfast under the presidency of the Marquis of Dufferin and Ava, at which papers of interest relating to library legislation and management, bibliography and literature, were read and discussed.

From the Library in Edinburgh there have been lent out upwards of 1300 volumes during the year, and there has been no falling off in the attendance. The library has been largely made use of by medical men and other persons to whom the Society is always pleased to offer facilities. The collection of books is growing rapidly, and the Council has added a considerable number of valuable standard works during the past year. The botanical department of the library has been specially enriched by a portion of the late Professor Bentley's library, these books having been already found a very useful addition. The shelf space in the present room is almost exhausted, but now that the examination work has been transferred to the new premises, it is intended that the present Board Room—which is admirably adapted for the purpose—shall be converted into a library, and that will add greatly to the comfort of readers.

MUSEUM OF THE SOCIETY.

The Museum has furnished material for the publication of papers and notes which have cleared up several doubtful points in materia medica, or have added to our knowledge of the medicinal properties and physiological action of plants. Dr. De Wney's paper on cubebes (Ph. J. [3], xxv., p. 314) is perhaps the most exhaustive that has yet appeared on the subject, and the greater proportion of the work was done in the Museum of the Society. A new kind of jaborandi that appeared in commerce has been shown to be derived from a hitherto undescribed species Pilocarpus trachyolphus (Ph. J. [3], xxiv., pp. 1065, 1066), and its comparatively little value, as compared with the Pernambuco kind, has been determined by Dr. B. H. Paul from material supplied by the Museum. Dr. R. Pfister, of Zurich, has published an excellent paper on the histology of the cinnamon barks of commerce, many specimens having been furnished by the Museum of the Society for the investigation (Ph. J. [3], xxiv., p. 941). Some leaves imported as a substitute for hops, which aroused considerable interest at the time both in England and on the Continent, were sent to the Museum for identification, and were proved, at the Kew Herbarium, to belong to Piptocalyx moorei, an Australian plant (Ph. J. [3], xxiv., pp. 977, 1044). Their bitterness was shown by Mr. J. C. Umney to be due to a glucoside. A British plant, Leonurus cardiaca, has been chemically investigated by Mr. Nayler (Ph. J. [3], xxv., p. 181), and attention directed to its therapeutical value (Ph. J. [3], xxv., pp. 180-181). Dr. R. Stockman, of Edinburgh, has demonstrated that prual root, aker lampong, and ipoh-aker, supplied by the Museum from material sent by Mr. L. Wray, Jun., of Perak, are distinctly poisonous plants, and he has described their physiological action (Ph. J. [3], xxiv., p. 561). Mr. H. N. Ridley, M.A., of Singapore, has contributed a number of native medicinal plants (Ph. J. [3], xxiv., p. 969), two of which, Ficus apocarpa, and Vitex veitia, appear worthy of investigation. The fruits of the former are said to be poisonous and the latter is used as an abortive. The properties of the genus Vitex have received less attention than they deserve, and they are comparatively little known, but appear to vary in different species, as in V. agnus castus and V. negundo. Clerodendron, another genus of the Verbenaceae, is also worthy of investigation, several species possessing medicinal properties, and one of them, C. stiphonanthus, is said by Mr. H. N. Ridley to yield the Biah leaves (Ph. J. [3], xxiv., p. 572), used in Perak according to Mr. L. Wray, Jun., as a substitute for opium (Ph. J. [3], xxiii., p. 389-390).

Other work has been done by corresponding members and travellers at the instigation of the Curator. Dr. J. E. T. Aitchison, F.R.S., now in Cashmir, has cleared up the uncertainty that existed concerning the collection of Assafotida from Ferula narthex (Ph. J. [3], xxv., p. 131). He has shown that in the district where the plant was originally found, none of the gum resin is collected for commercial purposes. He has also confirmed a previous supposition that Ferula jaeschkeana, VATKE, and F. fodiassima, REGEL, are distinct plants (see Ph. J. [3], xiii., p. 44). Mr. J. Medley Wood of Natal, has forwarded some of the poisonous plants of South Africa, and recorded their known properties, which in the case of Combretum bracteosis (the "hiccup nut"), and Dichrostachys interrupula used as a remedy for colds, certainly seem worthy of further investigation (Ph. J. [3], xxv., p. 273).

The specimens of opopanax and sagapenum, etc., brought home from Persia by Dr. E. Treharre Collins (Ph. J. [3], xxv., p. 404) have thrown fresh light on the hitherto almost unknown botanical origin and geographical source of these ancient drugs. Both the drugs were collected near Iepahan, and the opopanax in the fresh state is remarkable for its exceedingly powerful flavour of celery, which, taking into consideration the recent exports of this drug to Germany, must have been turned to account in commerce. The sagapenum, judging from specimens of an alliaceous plant received from Dr. Collins, is probably the produce of a species of Ferula nearly allied to F. alliacea, and perhaps identical with F. rubricaulis, but of which the leaves have not hitherto been collected.
Mr. J. Whitehead, now travelling in the Philippines, has contributed a species of Pittosporum (Ph. J. [3], xxv, p. 34), which has been described in a recent number of the New Bulletin (1894, p. 344) by Mr. Hemsl. as a new species. It is remarkable for the quantity of resin contained in the fruit, and has hence been named P. resiniferum. Mr. R. Thomson, of Bogota, has presented, amongst other interesting drugs, an herbarium specimen of a new species of cinchona, C. pombiana (Ph. J. [3], xxv, p. 319), which is rich in quinine, and a curious bark belonging to a species of Rhapala, which should possess some interest for biologists and forestry officers, since it proves invulnerable to forest fires, which kill the trees around it. Its immunity is probably due to the large amount of mineral matter deposited in the bark in the form of raphides, so considerable, indeed, that since it was introduced to notice a few years ago in the Gardeners’ Chronicle, no horticulturist has yet had the courage to ruin his rabbits in examining it. The life history of this plant, like that of the teak tree, and of the bamboo in which “tabashir” is deposited, should be of interest in solving some problems of vegetable chemistry.

As has always been the case since the Journal was commenced by Jacob Bell, fifty-three years ago, chief prominence has been given, in its pages during the past year, to such subjects as have proved to be most essential, from a professional point of view, for the perfect development of the modern pharmacist. The mere retailer of drugs may feel no need of advanced knowledge in the different branches of science, the progress of which is regularly recorded in the official organ; but the true pharmacist, who can see beyond his immediate necessities, will never begrudge the time and effort required to keep himself thoroughly abreast of the science of the day. The working pharmacist has also been assisted in his daily round by the publication of descriptions of new processes, and alterations in old ones. The “Month” and the “Notes and Queries” column have contained novel information and suggestions of practical utility, while much assistance, of which little or no permanent record is presented, has been rendered in individual cases of difficulty. Readers have been kept fully informed of the current literature pertaining to their craft, and a recent departure has been the insertion of illustrated descriptions of novelties.

In the present issue of the Journal this matter and other items appear in a new form—the change having been rendered necessary by the growing demands for space—and it is hoped that readers may assist by suggestions and otherwise in rendering the “Supplement” of the utmost value generally. Finally, with regard to students, the policy adopted has been to assist in their education more or less indirectly, not by the publication of special articles on elementary topics. In the “Students’ Number” some sound advice was given concerning education during apprenticeship, and, as remarked at that time, the whole tendency of the Journal is educational, especially if considered from the point of view of what is “liberal” education in pharmacy. As instances of useful articles in this respect, reference may be made to the series on Practical Pharmacognosy; the papers on the Nomenclature and Formulae of the Carbon Compounds, and on Systematic Botany; besides numerous reports and abstracts, such as those on Phosphorescence and Fluorescence, and Vegetable Ferments, and those of papers by Lauder Brunton, Braeman, Einhorn, Mennard, and others.

The endeavour to promote pharmaceutical education by maintaining a school where students can obtain sound instruction in the scientific principles on which the practice of pharmacy is based, has been continued as in previous years. The maintenance of the School and its extension, the Research Laboratory, has always involved considerable expenditure, and though the advantages thus offered cannot be shared by all students, it is much to be regretted that the number attending the School does not bear a much larger proportion to the total number of candidates for legal qualification. Of the necessity for thorough practical training for such an occupation as that of pharmacy there can be no doubt, and considerable expenditure of time on the part of students is, of course, necessary. Such thoroughness is especially aimed at in the Society’s School, but, unfortunately, in the absence of any regulations enforcing a definite period of study, the tendency of students is to unduly shorten the period of attendance. The establishment of a Research Laboratory was an important further development of the Society’s work in promoting education, and the opportunity for advanced study, now offered by scholarships in connection with it, should be a great inducement to students.

At the Council meeting in January, Mr. Atkins referred to the satisfactory working of the regulations as to the reduction of annuities in cases where the circumstances of annuitants had improved. At the meeting in May, Mr. Hampson brought forward a proposal to discontinue the election of annuitants by vote, in which he was supported by Mr. Young, Mr. Southall, and Mr. Harrison, but after a long
discussion the motion to introduce this alteration was negatived. At the meeting in October it was resolved that four annuitants should be elected in December, and that three applicants should be added to the list of approved candidates.

**WORK OF LOCAL PHARMACEUTICAL ORGANISATIONS.**

The proceedings of the various local pharmaceutical organisations, throughout the country, have been characterised during the past year by more than usual vitality. The Western Chemists' Association (of London) has increased its membership and extended its operations, so that it now fairly represents the whole of the metropolis. Its members have also continued to manifest deep interest in all questions of pharmaceutical interest, especially those affecting pharmaceutical policy, as instance by the discussions on the subjects of federation and amendment of the existing pharmacy law. The Manchester Pharmaceutical Association has been particularly prominent in this connexion, the more important proceedings being the address delivered by J. Rymer Young on the work of the Pharmaceutical Council, and the discussion on John Taylor's more recent address. Sheffield has recovered a little of its accustomed vigour, and holds out the promise of once more taking a leading place in the van of progress. C. O. Morrison's paper on pharmaceutical education in the provinces, a subject on which Sheffielders are peculiarly qualified to speak, attracted attention by the frankly-expressed heresies it embodied, and the delivery of the introductory sessional address by C. B. Allen afforded an opportunity of pleading for greater practical interest being taken by pharmaceutical students in the scholarships offered annually for competition. At the latest meeting held, some aspects of pharmaceutical politics were discussed. Both the Liverpool associations have continued to do useful work, the president of the senior organisation giving an instructive address at the beginning of the year.

The Three Towns and District Chemists' Association (Plymouth) has more than justified the expectations of its promoters, and papers of direct pharmaceutical interest have occupied the attention of both senior and junior sections. At Birmingham, John Barclay contributed some useful statistics concerning the purity of saffron, F. H. Alcock dealt with the amount of extractive in infusions, and F. Casson compared the strengths of various samples of extract of aconite. In the inaugural address by R. D. Gibson, a number of subjects that might be profitably discussed were suggested; and in a paper on tincture-making, H. W. Jones, advocating more general use of percolation, described a new form of percolator devised by himself.

Nottingham pharmacists have been gratified by the continued success of their educational scheme, and have also discussed a paper on hindrances to success, by R. D. Gibson, and one on the federation of local pharmaceutical associations, by H. Kemp. Glasgow has also shown that the enthusiasm amid which its Association was founded and extended, as yet shows no sign of abatement. In addition to a number of scientific and practical addresses, political matters have been considered, and the annual supper of the Association was made the occasion for a presentation to Alex. Kininmont, on his retirement from the Scottish Board of Examiners. The great event of the present session, however, has been the address given by the President of the Pharmaceutical Society, who was heartily received and sympathetically listened to whilst he explained the present position of affairs. At Edinburgh, the local trade association has dealt with difficulties arising in the administration of the Medicine Stamp Acts, and the new session was inaugurated with a capital address by Peter Boa, the newly-elected President. The Edinburgh Chemists' Association has, as usual, been favoured with a large number of practical communications, and has thus easily maintained its prominent position in relation to progress in the art of pharmacy. Amongst the more important papers were those on tincture of iodine, by C. F. Henry, and on the dispensing of percentage prescriptions, by C. A. MacPherson; whilst several dispensing difficulties were dealt with by Duncan and others, and points of importance regarding pharmaceutical apprentices and assistants were raised in the inaugural address by Alex. Sutherland. The Edinburgh Pharmacy Athletic Club has also had a successful year.

Amongst the remaining organisations, the Chemists' Assistants' Association (of London) has been favoured with several papers of general, and a few of pharmaceutical, interest, in addition to some ambitious and immature attempts to deal with questions which are quite beyond the scope of the Association or the capacity of its members to discuss. As a training for public speaking the Association does well to encourage discussions and debates, but it is ill-advised in permitting such experimental efforts—mostly instigated by youthful fervour or a boyish desire for notoriety—to be published. The School of Pharmacy Students' Association, whilst doing equally if not more valuable work, is wiser in this respect, and the little weaknesses of its members are not betrayed in its periodical reports. Of the papers read, that by H. B. Cox on tobaccos acquired a certain notoriety in the daily press, after publication in this Journal. Other useful communications were those on protoplasm, by Ernest Goulding; on aquatic plants, by C. E. Ashby; on photo-micrography, by Arthur Lander; and on capillarity, by T. Tickell. Reports on current science were also sent in, and the opening address for the current session was delivered by E. Hampson, Treasurer of the
Pharmaceutical Society. The Cambridge Association has also held several meetings, at which useful papers have been read, whilst the Aberdeen, Bristol, Brighton, Leeds, and Sunderland Associations have met less frequently than others, and apparently been less anxious about occupying much space in announcing their doings to the world of pharmacy. In several districts where formal associations do not exist, social and other meetings have been held from time to time, and doubtless done much good by bringing the local pharmacists together on common ground for the time being. At Oxford, during the Conference meeting, delegates from various associations met to consider the organisation of the proposed federation, and appointed officers. This, however, is the extent of what has yet been done in the matter, though it is understood a code of rules is now under consideration.

British PHARMACEUTICAL Conference was the old one of medicine and pharmacy, but in expressing views that were the outcome of more than thirty years' connection with the sister arts, Mr. Martin was fortunate in avoiding any semblance of sameness or repetition. Commencing with a review of the present condition of pharmacy, he exposed the weakness of the position occupied by those who endeavoured to cast the onus of all deficiencies upon the Pharmaceutical Society, and plainly showed the extent of the evil caused by the development of the proprietary medicine system. The comparative failure of the Pharmacy Act of 1868 was attributed to the free registration, without examination, of all who claimed to have been in business as chemists and druggists prior to the passing of the Act. Many of those persons had been antagonistic to the educational standards of the Society, or had even actively opposed them. The beneficial influence of the trade element in pharmacy was not likely to be readily nullified, and the outcome of it was that British pharmacists were attempting an impossibility—seeking to grasp commercial advantages and yet desiring to retain the rewards available only for professional services. Pharmacy as a trade was described as a failure, and, like the art of medicine, if conducted in the spirit of a commercial venture, deserved to fail. It ought to realise its privilege, and seriously take steps to accept its responsibilities as a profession. Proceeding next to deal with ways and means, Mr. Martin asked that the entrance examination should be rendered a more stringent test of intellectual powers and school training, and that this should be followed by a three years' actual apprenticeship and, later, by a two years' curriculum. Finally, the qualifying examination should attain the standard of the

Major, and successful candidates receive the qualification and title of pharmacist.

With regard to medicine, it was stated that no rigid line of demarcation between it and pharmacy is possible, and before medical men could be expected to relinquish dispensing, pharmacy must have acquired such a professional education and standing as will enable it to perform "its delicate and confidential function with the tact and reserve which is the outcome of prolonged training." Pharmacists made the mistake of expecting to receive the reward before making the necessary effort and becoming suitably equipped for their work. Prescribing by pharmacists must be strictly limited, so that there should be no rivalries or jealousies between medicine and pharmacy; and the better those who followed the two arts qualified themselves to exercise the duties devolving upon them, the more were they likely to respect each other's rights and work.

The papers subsequently read were up to the usual standard, the first being a note by Farr and Wright, on the stability of the alkaloidal tinctures. This was based on the examination of specimens prepared during the course of their long and useful work, the results of which have been published from time to time. They stated that the strength of such tinctures remains approximately the same for a considerable length of time, and also gave the results of a comparison of gravimetric and volumetric methods for the assay of the tinctures. The qualities of a typical dentifrice were discussed by Turner, Lucas suggested a modified process for extract of nux vomica, Ramsay showed that the seeds of nux vomica are preferable to those of Strychnos ignatia for pharmaceutical purposes, and Elborne commented on the structure of the stems of Gnetum.

An important paper by Parker dealt with the recovery of residual tinctures from marcs, and gave rise to a prolonged discussion. Some laboratory notes contributed by Bird—treatment of the use of potassium stearate in turpentine liniments, the quality of distilled waters, the preservation of syrup, hypophoesph. co. B.P.C., and repercolation as a B.P. process—were as practically useful as experience has proved most of his published methods to be, and also aroused much interest, though the limited time available unfortunately prohibited anything like a thorough thrashing out of the questions involved. In this connection it may be remarked that, whereas it may be a necessity under present conditions to economise time during the sessions of Conference, it does not seem advisable to effect this economy at the expense of practical matters.

Papers were also read on extract of malt with cod liver oil, and on the keeping qualities of certain samples of spirit of nitrous ether, by
Jones; an interesting dissertation on the natural features of the Oxford district was given by Drum; a comprehensive summary of information regarding animal extracts, by Stuart; papers on Leonurus cardiaca, by Holmes and Naylar; a contribution on the conditions of papain digestion, by Ridel; a recommendation of coco-nut stearin as the vehicle in suppositories, by Thompson; a suggested formula for phosphorus pills, by Parker; a plea for the systematic adoption of known rules of Latin grammar in naming official remedies, by Ince; and a historical account of the cultivation of medicinal rhubarb in England, by Usker, which was supplemented by some facts of value concerning henbane. The shortness of the time allowed for the sessions of Conference was unusually marked on this occasion, a number of papers being taken as read. These included a compilation of notes of pharmaceutical interest concerning rhubarb, by Proctor; an explanation of the varying behaviour of tinct. ergotis ammon. on the addition of water, by Hornflower; the recommendation of a soap basis for various official liniments, by Lucas; reports on the assay of samples of tincture of iodine, and the calibration of pipettes, by Livesedge; a paper on Indian hemp and its extract, by Hooper; and an exposure of some fallacies with regard to the testing of essence of lemon, by Barrett.

The Oxford meeting may be described as a distinctly popular one. Being held just at the beginning of the autumn vacation, many leading pharmacists, who do not regularly attend on account of holiday arrangements, were enabled to take part in the proceedings. In addition to the time being propitious, the place of meeting was well chosen, and, doubtless, attracted many who had not previously been privileged to become acquainted with the city and its University. The rich variety of the architectural surroundings, with their old-time associations, proved a source of great gratification to the visitors, and also provided a fitting opportunity for a novel departure in the Journal, where an attempt was made to reproduce in slight degree a few of the innumerable beauties that adorn the historically interesting city of Oxford. The arrangements made to enable the members of the Conference to attend the meeting on a more independent basis than has been customary in recent years, also proved successful, and, as already mentioned in the Journal, the smallest towns possessing the requisite accommodation may now look forward to entertaining the Conference without being unduly burdened by the responsibility.

Pharmacy. One of the earliest and most important contributions in pharmacy, during the year, was the paper by Professor Attfield on the proposed revision of the British Pharmacopoeia. This was written to explain the nature of some proposed alterations in the work, and with the desire to encourage pharmacists and others to assist in the labours of bringing it up to date from a scientific point of view and satisfactorily editing it. The main idea upon which the paper was based involves the extension of the Pharmacopoeia so as to make it "imperial" rather than merely national in its scope. It has been pointed out, however, by later writers on the subject, that this end is virtually served at present, and that all that is requisite is to permit, in the various colonies and dependencies, the substitution of such medicaments and alternative formulæ as may have been proved more suitable for local purposes than those official in this country. Recommendations to this end from Australia have appeared in the Journal. Reference was also made by Professor Attfield to the probability that pharmacists would be more directly recognised by the General Medical Council in the arrangements for the forthcoming revision. The whole question of revision came before the responsible authorities towards the end of the year, but nothing was definitely settled.

The annual report to the General Medical Council, on the progress of pharmacy in its relation to the revision of the Pharmacopoeia, afforded a further opportunity of acknowledging the indebtedness of the official reporter to pharmacists throughout Great Britain. In the case of all articles or preparations specifically mentioned in the report, full credit was given, wherever due, to those who by their work or observations had aided in the solution of many of the numerous problems that continually present themselves in progressive pharmacy. Amongst the more general views put forward in the report were those bearing on the retention of manufacturing processes in the Pharmacopoeia and the question of weights and measures. It appears probable that processes for the manufacture of definite chemical compounds will in future be replaced by extension of the statements of characters and of the tests to be applied. Official processes for galenical processes will still be retained, however, and with regard to weights and measures, it is proposed that formulæ shall be stated in terms of both the imperial and metric systems.

Some notes on belladonna preparations by Naylar confirmed Squire's assertion that the B.P.C. process for making chloroform of belladonna is wasteful, and no improvement upon the original method of simple percolation with chloroform. The results of some supplementary experiments to those on liquid belladonna plaster referred to at the Nottingham Conference meeting were published at the same time, and a formula for the preparation was given. A paper on granular
effervescent salts by Bradley gave several useful hints, and a number of others were embodied in the laboratory notes contributed by Lucas at an Evening Meeting in London. A practical instance of the utility of the application of aseptic and antiseptic principles in pharmacy was described in Whit's paper on the preservation of infusions. The use of starch in gelatin suppositories was recommended by Harding; a historical account of the introduction of Blaus's pills was contributed by Ince; the manufacture of wool-felt in America was described by Bush; and a large number of notes of lesser importance have also been published. Articles have appeared on the new Swiss Pharmacopoeia by Jeal, and on that of the United States of America by Beringer. The former was described as being "worthy of modern science," and the U.S.P., though criticised somewhat severely, was commended for its advanced position—"at least a decade in advance of the scientific attainments of the average American pharmacist." The tendency on the part of many pharmacists to afford excuses to medical practitioners for dispensing medicines has been discussed by Shaw, whose list of grievances against the former rests on firmer ground than is desirable; the somewhat decadent position of pharmacy in Germany served as the text of a special article; and a general consideration of the condition of pharmacy abroad served as a useful contrast to the position of affairs in this country. Pharmaceutical education has also received special attention, the necessity of thorough early training and systematic technical instruction being once more emphasised.

Pharmacography. During the past twelve months increased activity in the field of pharmacographic histology has been very prominent; an introduction to the histological study of drugs, which should prove useful to the student, has been furnished by a series of articles that have appeared in this Journal under the heading of "Practical Pharmacognosy." The anatomy of cassia bark has been exhaustively dealt with by Greener, who has shown that commercial specimens are by no means so uniform in their structure as has generally been considered, young barks showing conspicuous selerenchymatous fibres, the absence of which had been previously considered characteristic of cassia, whilst older specimens may show a structure approaching that of cinnamonodendron bark. The same worker has also identified an adulteration of veratrum root as that of an Asepheolous, and shown that structurally the two are practically identical.

Pfister has devoted much attention to the anatomical differences exhibited by cassia and cinnamon barks, and has embodied his results in an analytical table. Cubbea, which have always been a source of much trouble to pharmacognosists, have been exhaustively studied by Dr Wever, whose researches have thrown much light upon their anatomy, and indicated the substitutions that are likely to occur, as well as the anatomical characters by which they may be identified.

Pohl has investigated the rhizome of Hydrastis canadensis, and described the localization of the berberine, whilst Osenbrügge has dealt with the development and structure of the seed of Arca catechu. Hartwich has identified a false saracaparilla by its structure as the root of a species of Philodendron, and similar considerations have enabled him to refer a gum resembling tragacanth to a species of Sterculia. Based upon identity of structure was Mokler's opinion that Carthagenae ippecauennha is derived from the same plant as the sugary striated ippecauennha, an opinion which is contested by Hartwich, who refers the latter to Psychotria emetic".

The localization of the proximate constituents of plants, especially alkaloids and glucosides, has likewise been the subject of investigation. In this branch Braemar has rendered valuable service by an interesting summary of previous researches, whilst Clausthal has provisionally classified them according to their distribution in the tissues of seeds.

Tschirch and his pupils have continued their investigations, chemical and histological, on the secretions; the former has found that in all cases examined, oil or oleo-resin is secreted in the walls of the oil cell, or of the cells constituting the tapetal layer of the duct or cavity, not, as previously supposed, in the interior of the cell. Conrady has proved galbanum gum-resin to contain much more umbelliferone than had been suspected, and suggests that it exists in combination with a resin-alcohol, whilst Treg has shown that balsam of Peru is a pathological product, the liquid portion consisting almost entirely of benzyln benzste.

Schwenkfurth has rendered good service by determining the botanical source of myrrh. It is principally derived from Commiphora abyssinica, whilst Balsamodendron myrrha is entirely odourless, and yields no resin when incised. Ceará jaborandí has been ascertained by Holmes to be the leaflets of a hitherto undescribed species of Pilocarpus, which he has named P. trachylophus; they are distinguished by their hairy undersurface. Atkinson has shown some light upon the geographical source of asafoetida; none of this drug appears to be collected in Kashmir. The same traveller finds Ferula joshkeena to be celery-scented and distinct from F. futilissima (see page 588). Franchet has been enabled to refer the glabrous Strophanthus seed of commerce to S. (Roupel.) graut. Meyer and Sandland have drawn attention to the sophistication of loose kousso with male flowers, and Laws has detected poke root mixed with belladonna. Bastin
has examined the starch grains of cacao, Alessi
the means by which Martius yellow may be distin-
guished from the colouring matter of saffron, and
Beringer the solubility of podophyllin. Barker
has found *Pyrantherum lanceolatum* to contain
little else than volatile oil, whilst Hooper has
extracted from the leaves of *Abras precatorius* a
body apparently identical with glycyrrhizin, and
from *Brogania wallachii* an alkaloid. Liebchen-
ing has re-investigated kousoo flowers and isolated
an amorphous highly-active body, kosotoxin,
believed to be the active constituent. From
*Aconitum lycoctonum* Rosendahl has obtained
three alkaloids. The physiological action of
Malayan arrow-poisons has been investigated by
Stockman, but the scantiness of the supply and the
want of definite botanical identification of the
specimens detract from the scientific value of the
results. Bourquelot has found that several species
of *Polygala* and one of *Monotropa*, indigenous in
France, contain methyl-salicylic ether, or, at least,
yield it readily when crushed, and Brandes has
furnished an extremely interesting account of some
medicinal products yielded by plants belonging to
the natural order Diterocarpaceae, with special
reference to Gurjun balsam.

**BOTANY.**

The year has produced a con-
siderable amount of important work
in vegetable histology and physiology. More and
more attention is being given to the physiology of
the simplest forms of plants and to that of the
individual cell as a unit of construction of all
plants. In this department a great deal of enquiry
has been made into the question of karyokinesis or
the mitotic division of the nucleus in the new light
thrown upon the process by the discovery of the
almost universal presence in animal cells of the
"centrosphere" or "directing sphere," which
seems to play such an important part in guiding
the movements of the segments of the nucleus to
their new positions. The work of Guignard,
indicating the constant presence of the centrosphere
in plants, though accepted as far as regards the
lower forms, is the subject of much controversy
as far as the higher ones are concerned, many
observers, though adopting Guignard's methods
of work, failing to confirm his statements as to its
presence.

The continuity of protoplasm through the cell
wall, established long ago by Gardiner and others in
the endosperm of many seeds and in the pulvini of
certain Leguminoseae, and by other observers in
many of the seaweeds, has again been the subject
of a good deal of work. Wahlheim has examined
a great many of the fungi, with the result of
establishing the fact of the existence of protoplas-
mic continuity between the vegetable cells,
and also between the ascospores and the living
substance of the ascus. The means of communi-
cation is not, as in endosperms, a minute sieve-
plate, but generally a single central pore, contain-
ing a strand of protoplasm of uniform breadth,
usually granular in appearance. The pore appears
to exist from the time of formation of the cell
wall, and not to be, as in sieve-tubes, a new per-
formation. The discoveries of Hick and others as
to the continuity of living substance in the red sea-
weeds, have been supplemented by demonstration
of the same fact in many filamentous Algae, includ-
ing *Spirogyra* and *Ulothrix*. Porrault has discovered
similar structure in the lichens, where minute
channels are now found to exist in the cell walls of
the hyphae of the thallus and of the apothecia.
Botanists will be gratified to learn that W. GARDINER
has again taken up his researches into
this subject.

In connection with the physiology of the cell
several researches have been made during the year
into the peculiarities of chlorophyll. Of these
Monteverde's investigations may especially be
noted. He finds that the alcoholic extracts of
leaves contain two special pigments, carotin and
xanthophyll, besides chlorophyll proper. The
latter exists in two forms, one crystalline, the
other amorphous, the first of the two being prob-
ably the form in which the colouring matter exists
in living leaves. Etilolated leaves contain a modi-
fied pigment which the author calls "protochlor-
phyll," which, like chlorophyll, has a red flo-
scence. It gives only two absorption bands in
its spectrum, one corresponding to band iii. of
chlorophyll, and another peculiar to itself towards
the blue end of the spectrum. It does not exhibit
the band in the red so characteristic of chlorophyll.
Etard, also working at this subject, advances
reasons for suggestion that several distinct varieties
of chlorophyll exist in different leaves.

Some important investigations into gaseous
interchanges between leaves and the atmosphere
have recently been communicated to the Royal
Society by Blackman. By means of a very elabo-
rate piece of apparatus, the author has been able to
investigate and measure the interchanges connected
with an isolated leaf. He comes to conclusions
opposed to the view of Bossangault, that the
gases absorbed from the air make their way into
the interior by a process of solution in the cuticle,
but holding that the stomata are more important
than the latter in discharging this function. He
holds, however, that they are rather passive than
active in the work, only affording means of ingress
to the delicate cells of the interior of the leaf,
where solution takes place. The old idea that the
stomata are the breathing organs of the plant does
not receive much support from these researches,
as Blackman holds that respiration goes on
fully in those parts which possess no stomata.
MAQUENEE has also been investigating certain problems connected with respiration, particularly with regard to the immediate source of the CO₂ exhaled. His results lead him to adopt the view that the living cell is constantly forming a combustible substance, which, by simple exposure to air, oxidises and gives off CO₂.

The work on the localisation of the various active principles of plants, begun by GIGNARD, has been extended by many workers, particular attention having been given to the alkaloids, several of which have been examined by CLAUVRIAU, BAREMAC, and other investigators. In vegetable anatomy a very important paper has appeared by HARVEY-GEISSON in Schlipinella, dealing with a large number of species of that genus, and showing that a much greater variety of structure exists than has hitherto been supposed. Important work has been done on the relations of the vascular cryptogams to the mosses and lower forms by DOUGLAS CAMPBELL, BOWEN, and others.

Two important works on the science have been offered to the scientific student during the year, one of which should receive a warm welcome from all lovers of natural history. This is an English translation or edition of KENNER’S "Pflanzenleben," brought out by Professor F. W. OLIVER, of University College. The work is written in a most charming style, and while going into minute questions of structure and function, yet presents the facts of vegetable biology in so simple a way that it needs no preliminary acquaintance with the technical details of botany to be fascinated by it. The illustrations in which the work abounds are in every way admirable. The other work is the first half of Professor Vines’s new text-book. This has recently been reviewed in these columns that no more than a pass-ing reference to it is needed. It will supply a pressing need, containing as it does an immense amount of detailed information without being so bulky as many of the Continental textbooks that have been hitherto the only ones available for students who have wished to pursue the subject beyond its elementary stages. It is hoped that that monumental work, the 'Index Kewensis,' will be completed and in the hands of the public during the ensuing year. The value of this work to those engaged in the study of systematic botany cannot be over-estimated.

The results, such as they are, are the outcome of Lord RAYLEIGH’s observations on the density of nitrogen gas, in determining which he encountered some anomalous facts. At the Royal Institution the work of liquefying and solidifying the so-called permanent gases, and studying the characters of the resulting products, has been continued by Professor DEWAR, but hydrogen yet remains unconquered in its great elasticity. Chief amongst the phenomena studied at extremely low temperatures has been that of phosphorescence, and we have been fortunate in recording in the Journal a full and accurate report of an important lecture upon this subject.

Reports were current during the early part of the year that samples of glycerin in the market contained appreciable amounts of arsenic. As the result of the examination of a number of samples by PAUL and COWNLEY, the largest quantity of arsenic found in glycerin amounted to only one grain in fourteen pounds. FREUND and BECK arrived at the conclusion that aconitine is acetylbenzoyl-aconine, C₉H₁₄NO₃. They also disproved the statement that isoniaconitine (isonaconitine) is an isomer of aconitine, suggesting for it the formula C₉H₁₄NO₃, and confirming the previous indication by EHRENBERG and PURãFÜRT, that acetic acid is formed when aconitine is hydrolysed. DUNSTAN subsequently claimed priority in announcing that aconitine yields acetic acid when hydrolysed (see Ph. J., 20 Jan., 1894), although the results of EHRENBERG and PURãFÜRT were published some eighteen months earlier (see Ph. J., 30 July, 1892). KRAFFT and ROOS observed that sulphonie alky esters are formed on mixing sulphonochlorides with alcohols of the methyl series; MOSHAN prepared compounds of carbon with calcium and boron, respectively; BERTRAM and GILDEMEISTER investigated the composition of rose oil, and reconciled a number of discrepancies in the results of former workers.

BRAITHWAITE suggested that an official test should be based on the ash of sugar of milk, and that this should not be allowed to exceed 0.26 per cent.; the action of formic aldehyde as an anti-septic has engaged the attention of HOLFERT, SLATER, RIDGWAY, SCHMIDT, and others, whilst purified creosol solutions were recommended for the same purpose by GRUBER. JOHNSON published some observations on super-fatted soap, which were in part controverted by MOFFAT; the possibility of digestion without ferments has been discussed by DASTRE and BÉCHAMP; PAUL and COWNLEY have shown that Caris jaborandi leaves contain no pilocarpine, though a small quantity of an amorphous base is present, which forms a crystalline nitrate; and some common sources of error in testing for sugar in the urine were pointed out by Sir GEORGE JOHNSON.

CHEMISTRY. Progress in chemistry, though continuous, has not been marked by any startling developments, except the announcement by Lord RAYLEIGH and Professor RAMSEY that they have detected a hitherto unknown constituent of the atmosphere. Confirmation is yet wanting of this discovery, however, and chemists generally seem inclined to doubt its authenticity.
In addition to Dewar's work, experiments on phosphorescence have been performed by Jackson, and by Pictet; the chemistry of ipecacuanha has been investigated by Paul and Cownley, who find that emetine is associated in the plant with another base named cephaline, and that commercial emetine is a mixture of the two bases, whilst the probability was suggested that New Grenada ipecacuanha has a medicinal value, little, if at all, inferior to that of the Brazilian drug. The influence of alcohol on chloral hydrate has been studied by Schar; Holmes has summarised the results of the most recent work on the constituents of eucalyptus oil; and Duncan and Garnett have described two peculiar alkaloid-like bodies existing in Piper ovata (Piperaceae), and Anacystus pyrethrum (Composite), which greatly resemble each other in chemical, physical, and physiological properties. The results of a large number of other researches of greater or less importance have been recorded in the Journal, and particulars have been published of many new synthetic remedies, the invention and recommendation of which together constitute one of the most striking features of the applications of chemistry in modern medicine.

Amongst the more important new publications that have been noticed in the year is Tschirsch and Oberkle's pharmacognostic atlas, an indispensable aid to all who study the anatomy of drugs. Gamgee's work on the physiological chemistry of the animal body was concluded, the new volume being, as described at the time, a model of what an advanced text-book should be. A monthly review of current scientific investigation, entitled 'Science Progress,' has been commenced, the numbers so far issued containing many papers of the first importance. John's dictionary of the active principles of plants has proved as useful as anticipated, after making allowance for the manifest impossibility of making such a work all inclusive, and yet having it strictly accurate in every detail. The works by Oliver and Vines already mentioned are valuable additions to botanical bibliography. One other publication on the same subject was, in the interests of students, awarded more prominence than it would otherwise have received. Such works are perhaps best passed over in silence, but, under the circumstances, it seemed desirable to impress upon students the fact that the essentials of an important science cannot be compressed within what would ordinarily be the limits of a single chapter. In making a further bid for popularity, Squibb's 'Companion' shows no symptoms of falling off, and is fast approaching the position of the larger dispensatories without the drawback of their extreme bulk. Carnegie's 'Law and Theory in Chemistry'; Thimble's second volume on the tannins; the extension of Sawyer's 'Odorography'; Pavy's 'Physiology of the Carbohydrates'; Newth's text-book; and, above all, the concluding volume of Watts' valuable dictionary, all form useful and welcome contributions to the ever-extending literature of chemistry.

Another new work of importance is Brauns's 'Handwörterbuch der Pharmacie,' now approaching completion; whilst among new editions, the chief have been Quain's 'Dictionary of Medicine'; Phillips's 'Materia Medica'; Ince's 'Latin Grammar of Pharmacy'; the two large American dispensatories; and various hospital pharmacopoeias. Numerous minor works have also been published or republished, and altogether, the British pharmacist has been well served in the matter of new books, though one or two gaps still remain on his book-shelves awaiting occupants as yet unknown.

Death Roll. Among the more prominent names of the occurring in the year's obituary has been that of John Cartwright, brother of the President of the Pharmaceutical Society, who was at one time assistant to Michael Faraday, and, later, a partner in the firm of Dinnepford & Co., New Bond Street. A former member of the Pharmaceutical Council also passed away in the person of W. D. Savage, of Brighton; a former member of the Executive of the North British Branch, William Pinkerton; three of the founders of the Society, Joseph Beech, William Hooper, and Edward Horner, a member of the Salters' Company; Francis Thirkettle Silvers, Divisional Secretary for Dulwich; George Pattison, Divisional Secretary for Central Finsbury; Charles Batchelor, Local Secretary for Fareham; James Martin, Local Secretary for Motherwell; Walter Smyth, Local Secretary for Marthyn; and Cornelius Williams, Local Secretary for Pembroke Dock. Other notable deaths have been those of Professor Helmholtz, Dr. Brown-Squard, Dr. Alder Wright, Dr. A. H. Hassall, Henry Atscough Thompson, and, finally, towards the close of the year, Friedrich August Flickinger, a highly distinguished Honorary Member of the Society, whose obituary notice appeared but a fortnight ago.

Comparison of Filters for Domestic Use.

In concluding the first part of the account of their inquiry into the relative efficiency of water filters in the prevention of infective disease (British Medical Journal), Drs. G. Sims Woodhead and G. E. Cartwright Wood give a list of eighteen more or less well-known filters for domestic use, which, in their experiments, afforded no protection against the communication of water-borne disease. The three filters which did appear to afford such protection were the Pasteur-Chamberland, the Berkefeld, and Porcelaine d'Amiante. Where such filters are required their employment as tap or pressure filters is recommended.
Transactions of the Pharmaceutical Society of Great Britain.

MAJOR EXAMINATION QUESTIONS.

BOTANY AND MATERIA MEDICA* (A).
December 29.—Hours from 10 a.m. to 1 p.m.
1. How would you distinguish between the following Natural Orders?
   Solaraccae and Scrophulariaceae,
   Rosaccae and Ranunculaceae.
2. Give an account of the nature and distribution of glandular tissue in plants. In what plants and parts of such plants do we find resin, mucilage, volatile oils, tannins?
3. Describe the physical characters of official Strophanthus seeds. Mention substances that have appeared in commerce, and say how you would distinguish between them and the official Strophanthus.
4. The tip of a small seedling of Indian corn has a distinctly sweet taste. To what is this due? From what source and by what means has the sweet substance been derived?
5. Contrast a typical Vascular Cryptogram with a Moss. Give what you consider a convenient definition of the class Vascular Cryptograms.
6. What is the morphological nature of each of the following products?
   Mace, Kola Nuts, Ergot, Lycopodium.
   Give the geographical source of each.

BOTANY AND MATERIA MEDICA* (A).
December 29.—Hours from 2 to 5 p.m.
1. Describe in technical language the specimen B. Refer it to its Natural Order and Genus, giving the reasons for your assignment.
2. Examine the section of bark provided. Indicate by means of a lettered explanatory sketch the position of the several tissues seen in the preparation. Ascertain by means of micro-chemical tests what those tissues are, and write an account of the tests you apply, and their results.
3. What do you understand by assimilation, respiration, and transpiration? Give a brief account of the structure of a leaf, and point out how its tissues are adapted to each of these physiological processes.

BOTANY AND MATERIA MEDICA* (B).
December 29.—Hours from 10 a.m. to 1 p.m.
1. Describe in technical language the specimen B. Refer it to its Natural Order and Genus, giving the reasons for your assignment.
2. Examine the section of bark provided. Indicate by means of a lettered explanatory sketch the position of the several tissues seen in the preparation. Ascertain by means of micro-chemical tests what those tissues are, and write an account of the tests you apply, and their results.
3. What do you understand by root pressure? Give a brief account of the structure of the root, and show how it is correlated with this function.

BOTANY AND MATERIA MEDICA* (B).
December 29.—Hours from 2 to 5 p.m.
1. How would you distinguish between the following Natural Orders?
   Amarilliacae and Liliaceae.
   Compositae and Dipsacae.

* Part of the candidates received the papers AA, and the remainder had the papers BB.
2. Give an account of the nature and distribution of laticiferous tissues in plants. What substances are of most general occurrence in latex?
3. Describe the physical characters of official cubebes. Mention substances that have appeared in commerce, and say how you would distinguish between them and the official cubebes.
4. What chemical changes are associated with the process of germination? Explain them as far as possible.
5. Write the life history of a Moss. Compare the several stages with the corresponding ones in that of a Fern.
6. What is the morphological nature of each of the following products?
   Cloves, Levant Galls, Guarana, Cinnamon.
   Give the geographical source of each.

CHEMISTRY
December 29.—Hours from 10 a.m. to 1 p.m.

[Six questions only to be attempted.]
1. What is the constitution of the principal animal fats, and how are soaps obtained from them?
2. In what form does salicylic acid occur in nature, how is it artificially prepared, and how would you convert salicylic acid into paracarbonyl benzoic acid?
3. What are the principal alkaloids occurring in opium, and how is morphine separated from the rest? Give the names and formulae of any decomposition-products of morphine with which you may be acquainted.
4. How can the following substances be prepared from benzene.—(a) benzoic acid, (b) phenol, (c) anilino, (d) benzaldehyde?
5. What are ethylamine and acetamide, and how are they respectively obtained from ethyl alcohol? Indicate some of their more important properties and reactions.
6. How many lactic acids are known and what is their constitution, and how do they differ from each other in properties?
7. Distinguish between the terms decomposition and dissociation as commonly understood. Describe in detail any experiment illustrating the phenomena of dissociation.
8. A volumetric solution of sodium thiosulphate (hypochlorite) is frequently standardised by means of potassium dichromate. 0.0991 grammes of potassium dichromate were dissolved in water, acidulated with hydrochloric acid and mixed with excess of solution of potassium iodide. The iodine liberated was determined by means of the standard solution of sodium thiosulphate, and 20.9 C.c. were required. How much iodine and how much oxygen correspond to 1 C.c. of the standard solution? State precisely how the experiment should be performed, explaining, by equations the changes which take place (Cr₂O₇⁻²).
9. What is a reversible chemical change? Give examples.

PHYSICS.
December 29.—Hours from 2 to 5 p.m.

[Six Questions only to be attempted.]
1. Give a full account of the way in which you would determine the vapour density of carbon disulphide by means of Hofmann’s method.
2. Describe and explain all the phenomena attending the solution of sodium sulphate.
3. How would you experimentally determine the amount of heat liberated on diluting a given specimen of sulphuric acid with water?
4. Describe the construction of any form of polariscope, and indicate how it may be used for the quantitative estimation of cane sugar.
5. If 10 grammes of ice at 0° C. were mixed with 1000 grammes of water at 50° C. what would be the temperature of the mixture?
6. What is the principle of the induction coil? Describe arrangements for varying the power of the coil when it is used for medical purposes.
7. What is the principle of a constant battery? Illustrate the answer by examples of two or more forms of battery. What is a Clark's cell?
8. Two plane mirrors, each six inches square, are placed on a table with their surfaces vertical and with two edges in contact so as to form a right angle between their faces. A candle is placed a distance of one inch from the face of one mirror and two inches from the face of the other. Show by a rough diagram the paths of the rays and the position of the images seen by an eye looking towards the mirror between the mirrors.
9. Give some examples of freezing mixtures, stating the principles on which they depend.

EXAMINATIONS IN LONDON.
January 2, 1894.

MAJOR EXAMINATION—PASS LIST.

Marsh, A. E. ........................... Potter, H. A.
Massey, C. .............................. Taylor, C. J.

Proceedings of Societies in London.

THE WESTERN CHEMISTS' ASSOCIATION
(OF LONDON).
At a meeting held on Wednesday, December 19, 1894, the President gave an introductory address on the substance of which is here published—

THE COMMERICAL OUTLOOK OF PHARMACY.
BY E. H. PARKER.

After showing that evolutionary movement was the order of the universe, and that development of any species was the resultant of forces dependent upon its environment and its adaptability thereto, Mr. Parker indicated that pharmacists as a body are subject to the same laws, but have the infinite advantage of possessing conscious control of both. Regarding "human society" as an organism dependent for its vitality upon the supply of its requirements by groups of individuals (e.g., pharmacists), he asserted that the son of obtaining remuneration for that supply rested entirely on each group of individuals, and that "society" would remain utterly indifferent if pharmacists chose to supply such needs without demanding adequate recompense. It was evident, therefore, that pharmacists were themselves to blame if they did not by united effort command such remuneration as would enable them to maintain a thoroughly educated and competent body of men to act as "dispensers of medicine." Three methods of doing so were alluded to. (1) By further parliamentary legislation. (2) By turning to account
of existing legislative power, and (3) by individual and collective efforts to raise the status of pharmacy.

In the direction of further legislation he believed that "company pharmacy" could not now be prevented, but might be counteracted by demanding that every dispensing establishment should be registered, together with its qualified bonded manager, who would be held responsible for the proper conduct of that establishment only, and whose name might be struck off the Register for misconduct; secondly, that all dispensing should be performed by qualified persons only; and thirdly, that the educational status should be raised by means of a compulsory curriculum.

Possibly, in order to secure the elevation of pharmacy, so as to attract to its ranks talented men, the best legislative powers would be entirely futile, unless qualified chemists themselves insisted upon the public recognition of the value of their qualification, and individually endeavoured to assert its dignity.

Mr. Andrews proposed, and Mr. Urwick seconded, that a hearty vote of thanks be accorded to the President for his interesting and valuable address; this was carried unanimously and with acclamation.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The following is the programme of the above Association for the latter half of the session 1894-95:

Jan. 9 (Wednesday). Smoking Concert at the Horse Shoe Hotel, Tottenham Court Road.

31. Short papers by Members.

Feb. 7. Musical and Social Evening.

28. Short papers by Members.

Mar. 7. Annual Dinner.

28. Short papers by Members.

25. Paper, "Essential Oils in their relation to (1) the British Pharmacopeia, (2) to trade"—J. C. Uney.

May 2. Annual General Meeting.

Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

The usual meeting was held on Thursday, December 27. Mr. John McMillan, Hon. Vice-President, in the chair, when Mr. Alexander Boyd read a paper of which the following is a brief summary:

THE PRESENT ASPECTS OF PHARMACY.

BY ALEXANDER BOYD.

The author first dealt with the counter-prescribing question, from a historical point of view, the various Medical and Pharmacy Acts being briefly summarised in so far as they relate to the subject which, it was suggested, was not so great an evil as sometimes alleged.

The British Pharmacopeia next received attention, the efforts of pharmacists to become recog-

ised in its revision being referred to, after which various proposed alterations were considered.

With regard to proprietary medicines, pharmacists were recommended to sell them at the lowest possible prices and to educate their customers to dispense with them entirely.

Recent judicial interpretations of the Pharmacy Act, 1868, were next commented upon, and, finally, attention was drawn to the continued progress in synthetic chemistry and the development of the animal materia medica now taking place.

Afterwards various speakers commented on several of the points raised by Mr. Boyd, and showed themselves in sympathy with his views generally.

A hearty vote of thanks was accorded.

Provincial Transactions.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

A meeting of the above was held on Friday, December 22, Mr. Alderman Deck, President, in the chair, and an interesting paper was read by Mr. A. Irvatt, M.A., Christ's College, on "Reasons why certain Drugs and Chemicals of the Pharmacopoeia deteriorate." At the conclusion there was an interesting discussion, in which Mr. Alderman Deck, Mr. A. S. Camkin, J.P., Mr. E. S. Peck, Mr. Cook, and others took part. A hearty vote of thanks having been accorded, the meeting closed.

Parliamentary and Law Proceedings.

PROCEEDINGS UNDER THE MEDICINE STAMP DUTY ACTS.

SALE OF PROPRIETARY MEDICINES UNSTAMPED.

At the Plymouth Petty Sessions, on Dec. 27, before the Mayor and Messrs. H. J. Howland, E. Marshall, and J. Pillman, borough magistrates, Mr. Williams, chemist, Old Town Street, was summoned for supplying patent medicines which did not bear the Government stamp.—Mr. E. Hawkins, from Somerset House, London, opened the case, and referred to the question of the defendant in selling articles which should have borne the Government stamp.—Mr. G. Davis, supervisor of Inland Revenue at Plymouth, stated that on various dates he bought from defendant bottles of rheumatic sprain liniment, compound essence of horehound, squills, etc., compound of arnicas, Dr. Hawker's pills, and Fellows' syrup of hyposphathites.—Defendant having pleaded guilty, Mr. Trebana, who appeared for Mr. Williams, pointed out that the articles were supplied by an assistant.—There were five charges against the defendant, and he was fined £2 in each case with regard to selling of rheumatic liniment, essence of horehound, squills, compounds of arnicas, Dr. Hawker's pills, and Fellows' mixture—total, £13.—Western Morning News.

POISONING CASES AND INQUESTS.

POISONING BY LAUDANUM.

The body of a man, about 22 years of age, was found dead on Sunday, December 23, in the Nightingale Woods, a well-known valley at Portishead. By the side of the deceased was a glass tumbler, and in his pockets were five laudanum bottles, in which had been laudanum, evidently purchased at different shops. It is believed that the deceased poured the contents of all the bottles into the tumbler and drank the whole.—Standard.
Obituary.

Notice has been received of the death of the following:—

On October 28, by the wreck of a. s. Wairau, on Great Barrier Island, Charles W. Hill, chemist and druggist, of the firm of Wallace and Co., chemists, Christchurch, New Zealand. Mr. Hill was a native of Leeds, and was for several years engaged in the wholesale department of Messrs. Reynolds and Branson's business, with the President and Commissary, and was for a few years in the service of the New Zealand Drug Co., Limited. Mr. and Mrs. Hill had taken a holiday in New South Wales and were returning home by the ill-fated vessel when they both lost their lives.

They leave three young children.

On December 16, Crabb Gillett, Chemist and Druggist, Cambridge. (Aged 65.)

On December 21, Charles Love, Chemist and Druggist, Llanoncoast. (Aged 67.)

On December 22, John Beckett, Chemist and Druggist, York. (Aged 71.)

On December 24, William Cadd, Chemist and Druggist, Bideford. (Aged 82.)

On December 26, George Evans Morgan, Chemist and Druggist, Market Drayton. (Aged 69.)

Correspondence.

Some Parting Opinions.

SIR,—There is a slight misconception concerning the age of the Western Chemists' Association. Divisional secretaries were appointed in March, 1889, and at the first meeting, reported on page 821, you will also see—volume 21, page 133—the meeting at South Paddington, where there was a desire to form an association, and I was requested to amalgamate with them, and we formed the Western Association, believing that the stomach is the way to an Englishman's heart, I proposed a dinner to open the session, which took place October 28, 1890 (reported on page 836). After being appointed President, I was far as Hampstead in the north, Pimlico in the south, London Bridge in the east, Ealing in the west. I had about forty members in the N.K.A. and, altogether, induced over one hundred chemists to join. I had about 146 on the list when I left London, many of whom I did not expect to continue, and their present number is very satisfactory, I am sorry they will not join others in federation.

There are as many subjects as ever before chemists—

1. Company and soap chemists. I have often pointed out that all this could be cut short if chemists were true to themselves and their brethren, by not cutting themselves or giving their services to the enemy; they cannot carry on as associate members. What are men so short-sighted as to give them the power to do it?

2. The disabilities of Minor associates.—It is a pity, first, that membership should have given qualification. If it had been simply a society among chemists, all would meet on the same platform; C. members, D. members, and D., but as the Society had existed for twenty-six years before the C. and D. qualifications existed, I think that instead of the title "Associates in Business," they should be admitted associate members. It is a M.P. and A. is scarce of them justice, as the examination has continually been made more stringent. Oh! for the effect of that opposition which has always existed among chemists!

3. The future of pharmacy.—In the correspondence columns, page 70, of this volume, you published a letter of mine on apprentices; it would be useless to repeat it. The primary office of the pharmacist is to prepare and supply the medicines of the Pharmacopoeia, and to dispense prescriptions, and I think the apprentices' education should be based upon that; but the faith will not do. He must be a good botanist, understanding vegetable physiology, able to recognize true drugs and their qualities and adulterations, conversant with the microscope, o. m. c., and have a knowledge of the qualities of chemicals, conversant with their properties and the use of scientific apparatus, the polariscope, spectroscope, able to take specific gravities and use the test-tube, etc., up in analyses. I dare say he will soon learn physics, electricity, and photography at school. He should certainly know them, and, if he has a bent, he may take up any science as a "profitable extra"; but I should advocate attention to pharmacy proper as the correct thing. Ignorance is not bliss nor medicine will not give great success, but, as Mr. Jowett says, "there is plenty of room for the best," or, as I once saw it stated, "at the top," while the others are struggling for life at the bottom.

4. Post-graduate lectures, etc.—Why, in London there are, first, the Science and Art Classes at South Kensington, secondly, the Birchbeck Institution, a most thorough and excellent college, where there are even the most abstruse, and hundreds of similar institutions! Here we have in Reading a University Extension College, with evening classes on all subjects, and in most towns of any importance full facilities are offered. What more do you want? The only thing most wanted is shorter hours for pharmacy. Mr. Sutherland, at Glasgow, November 14, 1894, takes up the cudgels on behalf of assistants, and you, in one of your readers, support him. Now let me make it clear: are there not some who are most excellent assistants, and some who are not. "Palmair, etc." I have a great deal of experience of my own and from others on this point. Under twenty-one they cannot be admitted, and they are not allowed to be members for many years after, although all who are at work in pharmacy ought to be? At present, there seems to be a lack of qualified men. I have also been behind the scenes of a great many pharmacies where unregistered men are dispensing and taking a leading part, in places where you would least suspect it; and I am sorry to add there are still many who prefer them. I quite agree that a thoroughly qualified man is a great desideratum, and deserves every recognition, and there are plenty of posts open to him; but you often see advertisements in which it is stated there are two or more kept. An assistant generally takes a situation to improve himself, and often learns himself, and does not necessarily help the chemist. But I am sure of the preparations he has made at his situation. Surely this is part of the equivalent for his services. Then on the question of remuneration. Why, there are many chemists who cannot afford the luxuries of all, and generally the men who work longest. Could we not join the "Additional Curates' Society," and get grants for those poor fellows? On the question of home comforts, there is much to be said on both sides. The custom of living in is paying great in many cases, as they are the few very instances in which a chemist who wants a balance slightly on the right side can afford to keep a hotel, or indulge in high living. Perhaps someone in trying to do so, may discover what is the condition of the business; and there are many, if they were to pay high salaries and provide luxuries, would hand everything over to their assistants, and have nothing left for themselves or families. There is not only the difficulty of getting good assistants, but they do not stop long enough to be useful. A new assistant is not of much use, frequent changes are hurtful to the business, and it is true that West End houses now make them sign agreements, and stipulate for their continued service, against the public practice of pharmacy, and tried to do my best for it for 45 years, I am about to relinquish my connection with it, and bid you all "Farewell."

Reading.

HENRY LONG.

Communications received from Messrs. Addison, Olgies, Cierke, coaches, Cracnall, Dott, Gruer, Harries, Haynes, Hill, Ingram and Boyle, Jones, Kemp, Laying, Lowe, Perry, Radowsky, Wanklyn, Winter, Wright.
AN AUTOMATIC PROCESS FOR AQUA CHLOROFORMI.

BY WILLIAM KEANE, B.A.,
Pharmacist at University College Hospital, Demonstrator of Materia Medica at University College.

The B.P. process for preparing aqua chloroformi is to put the chloroform and water into a two-pint stoppered bottle and shake them together until the chloroform is entirely dissolved in the water.

The U.S.P. process is to "add enough chloroform to a convenient quantity of distilled water, contained in a dark amber-coloured bottle, to maintain a slight excess of the former, after the contents have been repeatedly and thoroughly agitated. When chloroform water is required for use, pour off the needed quantity of the solution, refill the bottle with distilled water and saturate it by thorough agitation, taking care that there be always an excess of chloroform present."

Now the B.P. process for aqua camphora is one of automatic diffusion of a solid volatile substance into distilled water: — "Enclose the camphor in a muslin bag, and attach this to a piece of glass, by means of which it may be kept at the bottom of the bottle containing the distilled water. Close the mouth of the bottle, macerate for at least two days, and then pour off the solution when it is required." In practice it is customary to keep a large excess of camphor in the bag, pouring off and replenishing with water until the whole of the camphor has disappeared—the operation extending possibly over months; this process, substituting stout parchment paper for the muslin bag, may be regarded as having suggested the following process.

In the sense of filtration, parchment paper is impervious to water, alcohol, chloroform, ether, and essential oils, but if such be enclosed in the parchment paper, and the latter suspended in a vessel of water, the enclosed liquids will, by osmosis, diffuse through the membrane into the water until, in the case of liquids freely miscible with each other, equilibrium within and without the membrane is established, or, if they be only sparingly soluble in water, until the latter becomes saturated: thus, if a fluid dramm of chloroform be enclosed in parchment paper and suspended in 20 ous. of distilled water, in a closed vessel excluded from light, it is found to have quitted the membrane and saturated the water in eight days, and if a large excess of chloroform be used (say two fluid ounces), retaining the same volume of water, saturation is affected in twenty-four hours.

The process having been in use for some months, has given every satisfaction. In the accompanying diagrammatic representation of the method adopted, B is an earthenware 4-gallon barrel containing distilled water; P, a pint of chloroform, tied up in a bag of stout parchment paper; S, the string passing round through the bung and spile-holes and supporting the bag; W, a dark amber-coloured Winchester quart filled with water, inverted and standing in the bung-hole, acting as a replenisher and gauge. The whole being placed in position is allowed to remain intact for seven days, after which period it may be drawn from the tap as required for use. The Winchester, when empty, is to be refilled with distilled water and again placed in position, and the chloroform bag replenished at much longer intervals. A saturated aqueous solution of chloroform is stronger than the B.P. aqua chloroformi, three parts of the former being equivalent to four parts of the latter.

For other medicated waters in considerable requisition, such as caust. pl., the process might prove of general application; but where the specific gravity of the essential oil is less than unity it would be requisite to load the flaps of the parchment with spare glass stoppers, in such a manner as to keep the bag at the bottom of the vessel, as represented in the lower part of the diagram.

With oil of peppermint thus arranged, the superimcumbent water certainly becomes highly impreg-
that will stand all the Pharmacopoeia tests for impurity; indeed, water, in the act of freezing, becomes completely separated from everything which is previously held in solution—a familiar physical fact of more than theoretical interest to the pharmacist.

**BISMUTH OXY SALICYLATE.**

By D. B. Dott.

This salt is usually simply described as bismuth salicylate, and there is probably no objection to the practice, as the normal salt (if it exists) is immediately decomposed by water into the basic salt and free acid, so that there is little likelihood of it obtaining a place in medicine. The formula of the basic salt is BiC₂H₃O₂(OH)₃, or BiO₂C₂H₅O₅H₂O. This salicylate has within recent years come considerably into demand for the treatment of gastric catarrh and some intestinal disorders. It has a bitter basic salt of bismuth, it is not perfectly white, but possesses a peculiarly greenish hue. It should yield more traces to ether. This is a most important test.

I have examined a sample commended on account of its whiteness, which gave 47.23 per cent. to ether. Such a salt is irritating and objectionable. When dissolved in two or three parts of boiling hydrochloric acid it should yield plenty of crystals on cooling. On complete ignition there should remain 61.31 per cent. of oxide, or very near it. If any of the oxide becomes reduced to metal in the ignition, it must of course be oxidised by nitric acid or otherwise. The salt must be free from chloride and nitrate, which it is very liable to contain when prepared by the method of double decomposition usually recommended. I have tried the most approved processes of this kind, but with quite unsatisfactory results. Addition of glycerin, of sodium chloride, and of ammonium chloride, has been recommended to prevent precipitation of basic salt of the stronger acids. Causse has given detailed instructions for the preparation of the salicylate, using a large proportion of sodium chloride to prevent formation of oxychloride of bismuth. If the figures as given in the 'Year-Book' are correct, the amount of hydrochloric acid is insufficient to dissolve the oxide (40 C.c. of acid to 35 grammes oxide of bismuth). However, I have followed the process exactly, and also tried some obvious modifications of the same, with the result that oxychloride was invariably present in very considerable quantity, salicylate being correspondingly deficient.

In one experiment a large amount of uncombined salicylic acid was found in the product. In the experiment, which was conducted exactly as described in the abstract so far as that could be understood, the resulting compound contained 0.9 per cent. free salicylic acid, and left 94.5 per cent. on ignition, an amount which is far in excess of the proper quantity. These experiments tend to explain the defects of some of the preparations found in the market, and shows the necessity for testing this salt, which will probably take a permanent place in the "materia medica." The tests above described will be found sufficient to practically indicate the purity of the preparation.

*Comptes rendus, xxiii., 547. 'Year-Book of Pharmacy,' 1892, p. 29.

**PREPARATIONS OF BLOOD-SERUM AS DRESSINGS FOR WOUNDS.**

The wonderful progress in surgery which has taken place within the past half-century owes its origin to a better knowledge of the nature of infective processes. It is known that even deep and complicated wounds heal readily if the affected parts can be kept at rest and free from bacteria. The drainage-tube which did such good service in giving an exit to the irritating and poisonous products of bacteria has now been largely discarded in the treatment of clean wounds, and useful industry has produced a wonderful variety of excellent materials for surgical dressings. Where the wound is made by the surgeon the surface of the skin can be cleansed and the instruments sterilised before the incision is made, and dressings of vegetable fibre, rendered sterile by heat, are to a large extent replacing dressings which have been impregnated with saline broths or other germicides. But, for accidental wounds and septic cavities, antiseptic surgery must ever hold its own, and it is to be hoped that before the rising generation has attained years of responsibility, the disastrous use of the lined poultries to cut and other common injuries of the surface will have been relinquished, even by the million, in favour of, say, carbolic acid lotion.

Seeing that the method of the treatment of wounds and sores is of such paramount importance, and that dressings are continually being modified and improved by many physicians to follow every new development in surgical therapeutics, in order to know what to keep ready for the use of medical men and for sudden emergency. In the November number of the 'Therapeutische Monatsshefte,' Dr. Schleisch describes certain dressings for septic wounds, and media for the application of drugs to the skin and accessible mucous surfaces. The author reminds us that absolute asepsis is hardly attainable in any wound, and that on the cells of the incised tissue healthy repair ultimately begins to obtain. Therefore unless the dressing next the wound should not be injurious to the living cells in contact with it. For this purpose Schleisch has prepared a powder of dried and sterilised serum of ox-blood. After cleansing the surface of wound, grate, eczematous patch, or clean ulcer, this powder is dusted on, and it dries in the air to a crust. The powder for septic wounds can be obtained mixed with boracic acid, iodiform, etc.

It would seem that the medicated powder might be the more useful, for it would be extremely difficult to keep the simple preparation aseptic when once the packet has been opened and dust and damp have obtained access to it. A more extended applicability may perhaps be found for another modification of the serum-powder. This is a paste (Pasta Serosa, Schleisch) made with the sterile powder mixed with wax and zinc oxide and freed from water. It is described as having the consistency of honey. It is said to spread readily with a brush over diseased surfaces, where it rapidly sets to an elastic film. The paste can be made the vehicle of drugs, such as ichthyol, chrysarobin, resorcin, lycopodium, etc. The paste is said to mix with mercury in the same proportion and with sal-ammoniac and sal-sal-ammoniac. Thus it appears the preparation may have an extensive usefulness in dermatological practice.
A third preparation is Schleich's Pasta Peptonata. This is made with Adamkiewicz's peptone, added to wax, gum, oxide of zinc, and starch. The author uses this as a means of applying gauze dressings to wounds, etc., of the scalp, neck, buttocks, etc., where bandages do not sit well. A ring of the paste is painted around the wound, and a circle of gauze is cut out and pressed on the wound and the ring of paste. The latter sets firmly in five to ten minutes. To change the dressing, the gauze is cut just inside the ring of adhesive paste, a fresh ring painted over the old one, and a new disc of gauze applied. When the wound has healed the paste can be washed off, as it dissolves readily in water. This paste can be used mixed with iodiform, and the author claims for it an advantage over collodion in that it does not contract and crumple the skin, and that it can be used as an application to moist surfaces. All of Dr. Schleich's preparations can be obtained from Herr Kohlmeier, Bellealliancstr, 12, Berlin, S.W.

THE PASSING OF THE TABLET FAD.

Unquestionably one of the greatest evils from which legitimate pharmacy and medicine suffer is the indiscriminate use of compressed tablets. Beginning in a small way, they have gradually increased in use until now they threaten to overthrow all other form of preparations. Their convenience, portability, and cheapness are elements that appeal to many, and in the case of inorganic chemicals and well-defined organic compounds, like strychnine, morphine, atropine, etc., they afford, in many cases, a valuable means of drug-administration, but the danger to legitimate pharmacy and medicine lies not in the use of the tablet, but in its abuse; and it is upon this matter that we wish to speak.

In the evolution of drug-administration different forms of preparations have successively arisen. Crude drugs have been followed by infusions, and these by tinctures, extracts, fluid extracts, and active principles. None of these, however, has wholly replaced the others. Each class has shown special value, and met special indications in disease-treatment. Hence, as a result, medicine has had her implements of treatment largely increased, and pharmacy has broadened in work.

But in the use of tablets a different result is sought. The tablet faddists claim that all medicinal preparations should be given in the form of tablets, and like all extremists they are wrong. After the fad is over, it will be found that tablets afford a valuable means of drug-administration in certain cases, and may be used at times with advantage. That they will permanently replace all the older forms of preparation, we do not believe possible, especially in the case of preparations of drugs of organic origin, for the reason that tablets cannot be made to contain the same proximate principles, in the same soluble form, and in the same proportion, as found in various galenical preparations. Even if it were possible to do this, the tablet does not afford the readiness of assimilation and resulting promptness in action given by other forms of preparations, notably the liquid ones.

Now, when physicians learn that they cannot get as good therapeutical results with tablets as with other forms of medicaments, they will use tablets for special cases only—after the present fad subsides, for like all other men, including the pharmacist, the modern physician must have his fad.

The abuse of the tablet lies in the endeavour made to have it replace all other forms of drug preparations. Notably is this so in the case of tablets alleged to represent tinctures and fluid extracts. Granting that the liquid preparations be rightly made, we believe that the heat used in concentrating and drying them with the diluent to make the powder for the tablet, must result in an alteration of the proximate principles of the drug, both in proportion and kind.

Heat is a most important factor in altering the character and amount of active principles in a drug preparation. Take, for example, digitalis infusion. M. Roger has shown (Amer. Journ. Pharm., 1889, 174) that the toxicity of digitalis infusion is very notably diminished when the product of maceration is simply concentrated on a water-bath; from 90 to 150 times the amount of the heated product being required to cause death, as compared with the cold water product. What is true of infusion of digitalis when heated, is very probably true of other drug preparations.

How the commercial tablets alleged to represent galenical preparations are made is known only in a general way; each manufacturer following his own working details. We have been informed, however, on good authority, of a practice pursued by one manufacturer in the making of tablets of the so-called narcotic tinctures (i.e., aconite, belladonna, digitalis, etc.), which, if true, is open to the severest censure. This manufacturer, finding that his tablets of these tinctures stick together on keeping in stock, adopted a new procedure. Instead of making the tablets contain the tincture in minims, as represented, he makes a fluid extract of the drug, evaporates to a thick consistency, washes with petroleum benzine to remove resin, colouring matter and benzil soluble extractive, spreads on plates, dries with heat, and makes up into tablets.

Now, apart from the question as to whether this benzil treatment removes or alters any active principles or not, the fact remains that such tablets are not what they are represented to be. Instead of being made of tinctures, as claimed, they are made of fluid extracts, concentrated by heat, washed with a solvent that removes certain proximate principles, and then heated to eliminate the persistently remaining traces of benzil, which heat probably modifies, if it does not destroy, the remaining proximate constituents. The most enthusiastic tablet faddist can hardly claim that tablets made in this way are fit to replace properly-made tinctures.

Whether this practice is followed by other manufacturers or not we do not know, but we believe that the surest way for physicians to get the best therapeutical results with drugs of organic origin is to use properly-made tinctures and other galenical preparations made by pharmacists. These preparations may vary somewhat, from natural causes, in their proportion of active principles, but they vary no more than
the varying personalities of sick patients, and as they are usually given until physiological effects are had, the danger in the use of non-standardised preparations of potent drugs is more apparent than real, and has been greatly exaggerated.

We believe that tablets have had their day, or rather have reached their zenith of popularity, and like every form of drug-preparation that has preceded them, will pass away, in part at least, to make room for something else; and when this takes place, physicians will then be found to cry to the newcomer, as they do now with the older galenical preparations and the compressed tablet: "Le roi est mort. Vive le roi!" It should be the aim of physicians and pharmacists everywhere, to work together to discourage the abuse of the tablet form of drug-administration.—Alumni Report.

READY-MADE THERAPEUTICS.

Some of our readers will, perhaps, recall the heavy villain in the Oriental tale, who used his bed as an instrument of torture. When the victim was short, he was put through a course of elongation, the sinews and muscles being wrung until life was extinct; when too long for the bed, the extremities of the poor wretch were suitably abbreviated.

One of the mischiefs which spring from drug-dispensing by physicians strongly suggests the Arabian story. We refer to the disposition which this practice may engender, to stretch a point in using the medicine at hand when the precise indications of the case cannot be met. Not having what he wants, the dispensing physician is sometimes tempted to use what he has. Thus arises a propensity to make the case fit the remedy, whereas the remedy should fit the case—to forget that medicine was made for man, not man for medicine. Now, if precision in therapeutics is worth anything, it is assuredly fitting to point out the loose, unprofessional habit which may result to the physician from doing his own dispensing.

An evil by far more serious, however, is illustrated by the following incident, related in conversation by the editor of the Medical Age. Having occasion to remove from their old resting-place the books and instruments in his father's office, he found a parcel of tablet triturates recently left by the representative of a tablet-manufacturer. A brother practitioner occupied a neighbouring office, and the tablets were handed to him for future use. The gift was vigorously declined: "No, thank you; I don't want them. I don't employ them myself, and I think it's a sin to counsel their use. These tablet triturates are doing serious mischief. Many of our young practitioners, fresh from college, are not strong in their therapeutics. When at a loss for suitable remedies, they look up the price-list of the tablet-maker, ascertain the various remedies employed in the given disease, make their pick, and then dispense. Suppose I have a case of bronchitis. I simply look up bronchitis in the list—I see 'bronchitis tablets'—Eureka!"

It is plain that under these circumstances the young physician is not specially impelled to acquire a solid knowledge of therapeutics. Study is hard work, and of most men it is emphatically true that they study only what they must. The tablet triturate is accordingly an ever present temptation; it demoralises—it causes the physician to look upon his price-list as a compendium of therapeutics, deludes him into the notion that he has found a quick and easy road to the cure of disease, or at the best begets a mechanical, routine habit of prescribing.

No one will venture to compare tablet triturates with the wonderful instruments of precision which have been introduced into modern medicine—the stethoscope, the fever thermometer, the sphygmograph, the pleximeter, etc. And yet we have heard veteran practitioners, who used and valued these auxiliaries at their true worth, deplore the effect which they were plainly exerting on the younger generation of medical men. Too great is the reliance placed on these instruments of precision—too little the pains taken to train the perceptions. Not a few treat the thermometer instead of the fever. Frequently the physician becomes the slave of his implements, and what were intended as his aids prove his undoing by inducing a neglect to cultivate the eye, the ear, the touch.

The truth of our contention is so glaring that it cannot fail to make an impression on the dispensing physician if tactfully, diplomatically presented by the druggist. It surely is no strain on the powers of persuation to convince the doctor that his wisest course is to treat disease as best he can without regard to his stock of tablet triturates, and that he is the sufferer when he makes his diagnosis with one eye on the contents of his tablet case.—Bulletin of Pharmacy.

PHARMACY IN ITALY.

MEDICINE TARIFF.

The prices of medicine provided by law in Italy are fair, some higher and some lower than those in vogue in England. The following, taken haphazard, will give an idea of the scale:

</table>
The action of the poison may be described under two heads, (1) local and (2) general effects. The most marked of the local effects is edema; the general symptoms consist of twitching and convulsions in non-lethal doses. A fatal dose kills within a few seconds or minutes. There is also a peculiar effect on the blood.

The conception put forward of the formation of these albumoses is the following:—The cells of the venom-gland by a vital process exercise a hydrating influence on the albumoses supplied to them by the blood, the results of which influence are the albumoses found in the venom. The difference between this process and digestion by peptic or by anthrax bacillus is that the hydration stops short at the albumose stage, and is not continued so as to form peptone or simpler nitrogenous products like leucine, tyrosine, or alkaloids. Gland epithelium is certainly capable of exerting such a hydrating influence; the conversion of glycoside into sugar by the liver cells is one of the best known examples.

The effect of snake venom on the blood opens up other questions. Fontana, more than a hundred years ago, noticed that the blood remained fluid in animals dead of viper bite, and Brainard, writing forty years back, states that when death occurred immediately in animals bitten by rattlesnakes the blood was found at the post-mortem examination to be clotted; but if some time elapsed before the animal succumbed, the blood remained fluid in the vessels. The continued fluidity of the blood has since then been noted by numerous observers in the case of various snakes.

Martin made most of his observations on dogs, but obtained confirmatory results on other animals (cats and rabbits). He found that different doses produced different results. Immediately after the introduction of the venom the coagulability of the blood increases, and this increase in the case of moderate or large doses (more than 0.0001 gramme per kilo. of body weight) culminates in intravascular clotting of greater or less extent. The injection of smaller doses produces a transient phase of increased coagulability, but after two minutes this is succeeded by a "negative phase"; the blood drawn either fails to clot at all, or does so only after the lapse of several hours. The thrombosis occurs more readily in venous than arterial blood, and is frequently confined to the portal area.

These results show a great resemblance between the action of the venom and that of tissue-fibrogen or nucleo-albumin. The effect of diminished coagulability is not unexpected, seeing that the principal substance in the venom is albumose. But the minute-ness of the dose necessary is very striking and distinctive.

The question arises, does the poison contain nucleo-albumin? A nucleo-albumin is a proteid united to a substance rich in phosphorus, called nuclein. It can be detected by the fact that artificial gastric digestion dissolves the proteid and leaves the nuclein as an insoluble residue. This residue must then be examined for phosphorus. Snake venom contains no nucleo-albumin; and its action not only opens up a novel aspect of the subject of snake poisoning, but also sheds light on the vexed problem of blood coagulation.

The smallness of the dose suggests that the injected material does not contribute itself to fibrin formation. Probably it acts by producing disintegration of the cells in proximity to the blood stream, such as the endothelial cells lining the vascular system. If it thus liberates nucleo-albumin from these the conditions would be practically the same as if this toxic agent were injected from without. The venom is capable of playing havoc with these cells. This was originally shown by Weiz Mitchell and Reichert. These authors moistened the mesentery of a cat with a solution of rattlesnake venom, and observed under the microscope the rapid formation of extensive capillary hemorrhages. Martin repeated these experiments, using black snake venom; and although the action of this poison is less rapid than was the case in Mitchell's experiments, the results were identical.

Whether the venom causes any destruction of the white blood corpuscles is doubtful. These are massed together in such a way that their enumeration becomes a difficult matter. The plasma is stained with hemoglobin, indicating that a slight solvent action on the red corpuscles has taken place. This, however, is not a distinctive action of snake venom. It is, moreover, well known that substances like distilled water which produce extensive disintegration of blood corpuscles within the blood stream never produce thrombosis; so that, even if the venom produces a disappearance of the leucocytes, that would in itself be insufficient to cause intravascular coagulation.

From this summary of the subject of snake poison one sees how much of interest exists in such researches. They open up fresh questions in wide and important general subjects, two of which, namely, blood coagulation and the poisonous nature of certain proteids, it has been the object of this paper specially to emphasize.

THE ALKALOIDS OF COD LIVER OIL. *

BY J. O. SCHLOTTBRECK, PH.C., B.S.,
Instructor in Pharmacy and in Botany, in charge of Materia Medica; University of Michigan School of Pharmacy.

My attention was first directly called to this subject about one year ago, at which time I was requested to make some microscopical drawings of crystals that were said to be alkaloids obtained from cod liver oil. Although I had heard of the discovery by two eminent French chemists of alkaloids in this important medicament, I had been rather sceptical of their presence, and, naturally, was tempted to test these crystalline products for alkaloids. They responded in a decided manner to the usual re-agents employed for detecting such compounds. From that time on my interest in cod liver oil continued to increase, and I have decided, if circumstances permit, to make a thorough study of these organic bases.

* From The Pharmaceutical Era.
A glance through the pharmaceutical, chemical, and medical periodicals for the past forty years or more will satisfy anyone that this drug (if it may be so called) has received due attention from scientific investigators. Many careful analyses of the oil have been made and the results published, only to be largely contradicted by later workers. To be sure, in some particulars the results were fairly concordant; as, for instance, in the case of the glycerides of the fatty acids. Unfortunately, however, this agreement is of no special value, glycerides of the fatty acids being component parts also of the more common fixed oils, which cannot be considered as substitutes for cod liver oil.

A theory long in favour held that the iodine and bromine found in cod liver oil were important, active constituents, but it is a fact that some oils, especially those that are light-coloured, contain none of these elements. At most there is but 0.00323 per cent. of iodine present, and even if it be in organic combination (a point of which much is made), the quantity is too small to be of practical benefit. The same may be said of bromine.

Then, again, it was advocated that there were biliary principles in the oil which mechanically or otherwise aided in the absorption of fat through the villi of the intestines, but there are many who doubt the presence of these principles, especially in the light oil. According to others, free acids are the cause of the easy emulification, and, consequently, of the rapid absorption of the oil; yet, if we are to believe that the light oil is superior in therapeutic efficacy to ordinary fixed oils, then it seems that these cannot be important factors, since it is positively stated that only the coloured oils contain appreciable quantities of free acids. Indeed, the statement has been frequently made by clinicians that the light-brown oil is much superior in every particular to the light, and that it is a great mistake to reject the essential constituents for the sake of securing elegant appearance.

It will be seen that there is a great diversity of opinion as to the real active constituents of cod liver oil. We believe some of them to be more or less responsible for the medicinal effects produced, but it would seem, in the light of the above statements, that the administration of light-coloured cod liver oil is rather inconsistent. As yet the chemistry of cod liver oil has not been sufficiently determined to admit of its administration on a rational basis.

The first substantial work upon cod liver oil was done by De Jongh in 1843, but though his analyses show careful and extended manipulations, he did not suspect the presence of alkaloids. In 1887 E. Chasenoud published an exhaustive report of his clinical studies upon mornhulin—an extract of light brown cod liver oil claimed by Chapoteau to contain the organic bases. Chasenoud concludes that mornhulin—

1. Augments the appetite and regulates the digestive functions.
2. Causes rapid increase in the weight of the body, and consequently improves the general physical condition.
3. Causes increased excretion of urine.
4. Ameliorates and cures cough and all pathological conditions dependent upon general debility.

Virtually the only trustworthy research upon the alkaloids of cod liver oil has been conducted by Gautier and Mourgues, 1888–90. Armand Gautier, by the way, has probably studied leucamines more thoroughly than any other man, and the reports of his investigations on ptomaines fill many pages in the transactions of the French Academy of Sciences. The presence of alkaloidal bodies in living tissue was known for many years, but it was left for this chemist to study systematically these substances, to which he gave the name leucamines. Under this title he includes all organic nitrogenous bases found in living tissue as the result of physiological metabolism, in contradistinction to ptomaines, the alkaloidal products formed during putrefaction. Gautier says that the leucamines are secreted under the influence of the action of muscles, glands, and nerve centres, and must be considered as constant residues of life.

Strecker's discovery of choline in the bile led Gautier and Mourgues to engage in a continued study of cod liver oil, with the hope of finding alkaloids. Their work extended over a period of several years, and the details of their investigations and their conclusions as to the active principles of cod liver oil may be found in their original monograph. Their suspicions as to the existence of these alkaloids were confirmed, and they were able, after repeated operations, to separate completely the following alkaloids:—Butylamine $\text{C}_6\text{H}_5\text{N}$, amylamine $\text{C}_6\text{H}_5\text{N}$, hezylamine $\text{C}_6\text{H}_5\text{N}$, dihydroxyline $\text{C}_6\text{H}_5\text{N}$, assoleine $\text{C}_6\text{H}_5\text{N}$, mornhulin $\text{C}_6\text{H}_5\text{N}$. They then made a long series of physiological experiments with each one of these principles and concluded that cod liver oil acts mainly by the alkaloids which it contains. It stimulates the nervous system, augments the appetite, accelerates intra-organic oxidation, and increases the secretion of urine and sweat. The observations of De Jongh and of many other celebrated physicians upon the effects produced by light-brown oil are incontestably verified by these experiments, since the alkaloids were obtained from this kind of oil.

In 1892 M. J. Bouillot, by micro-chemical methods, proved the presence of these same alkaloids in the fresh liver of the cod. They are, therefore, leucamines, and not ptomaines. This same chemist prepared some of the combined alkaloids by the method of Gautier and Mourgues, and carefully conducted a series of physiological experiments on animals and then on man. His results demonstrated these alkaloids to be possessed of marked therapeutic power. They stimulate nutrition and circulation, and act as powerful diuretics. He believes in the practicality of isolating in a mass these alkaloids, and dispensing them in the pharmacies precisely as the alkaloids of plants are now dispensed. It may be said that the individual alkaloids of this mixture are not always the same, and would not always exist in the same proportion. But if these principles are leucamines, the first objection cannot hold good. Since the name leucamine implies a constant product of normal
physiological activity in animal tissue, it would be as
reasonable to expect to vary in composition as we
would expect the concrete juice of the poppy to yield
morphine at one time and strychnine or some other
alkaloidal body at another. To meet the second objec-
tion, that they may not exist in the same proportion,
we may cite many parallel cases in plant life. We
can find no plant containing two or more alkaloids in
which the proportion of these principles is always
uniform. As examples, digitalis, aconite, jaborandi,
and physostigma may be mentioned.

The distinction between vegetable and animal alka-
loids is not very well defined, and, in fact, there seem
to be reasons for considering their formation as due
to the same causes which bear an intimate relation to
the physiology of the cells and tissues of both king-
doms. Thus, vegetable tissues are known to contain
not only definite pteromelines, such as cholines, but also
leucinamines, as hypoxanthine, xanthine, etc. Indeed,
in this latter group must be placed, on account of their
relation to xanthine, those well-defined alkaloidal bases
caffeine and theobromine. Not only are the repre-
sentatives of these two divisions of basic substances
common to both kingdoms, but their parent bodies,
leucithin, mucin, etc., are known to occur in both, thus
giving rise to the same bases on decomposition.

Alkaloids are defined as organic nitrogenous bases
developed in plant tissues; in fact, the term alkaloids
has heretofore implied a vegetable origin. Leuco-
maines, as stated above, are similar chemical com-
ounds, produced, however, by animal cells. Ptero-
maines are formed by micro-organisms, either animal
or vegetable. These three divisions of basic substances
are all alkaloids, products of cell activity, on the one
hand produced by cells united to form tissue, and on
the other by isolated unicellular organisms. They act
by virtue of their chemical constitution, regardless of
their source. Therefore, the three above divisions are
purely artificial, made for the sake of convenience.
An evidence of the close relationship existing between
vegetable and animal alkaloids is the discovery of
leucinamines and pteromelines similar in properties to
stropine, strychnine, morphine, and codein.

As far as we know, the protoplasm of animal and
vegetable cells is the same. The above-mentioned
products differ then only in the source from which
they are obtained, and not in their general chemical
constitution. It appears very reasonable, then, that
sooner or later these principles will be used as vege-
table alkaloids now are.

The terms leucinamines and pteromelines are
apparently associated by the masses with something
ghostly, death-like, or extremely poisonous. The fact
is, the majority of these compounds are harmless,
though not inert, and it will be only a question of
time when the superstitions regarding this class of
substances will be overcome. What objection can
there be to using alkaloids possessing valuable therapeu-
tic power, even if they be derived from the animal
kingdom? If we can obtain leucinamines or even
pteromelines in a high state of purity and possessing the
same physiological activities as vegetable alkaloids,

there is no tangible reason why they should not be
employed for the same purposes.

Since no extended investigations have been made to
verify the work of Gantier and Mourgues, I have
deemed the subject worthy a thorough study, and
have accordingly planned the following outline:

I. To separate the combined alkaloids in as pure a
condition as possible and determine their power of
forming salts with mineral and organic acids.

II. To establish tests for the identity of the com-
combined alkaloids.

III. To subject these alkaloids to physiological
experimentation upon the lower animals.

IV. To attempt the isolation of the individual
alkaloids in a pure state, to form crystalline salts with
the different acids, to establish identification tests,
and to subject them to physiological experimentation.

V. To verify the work of Bouillot upon the existence
of alkaloids in the fresh liver of the cod.

Preliminary examination of small quantities of
Norway, Newfoundland, and Maine oils showed the
presence of alkaloids in varying quantities. One
hundred kilos of light brown Norway oil were extracted
with some modifications, according to the method of
Gantier and Mourgues, and about thirty-five to forty-
five grammes of slightly coloured salts of the alkaloid
were obtained. They are crystallizable in the form of
tartrates, citrates, acetates, oxalates, sulphates, and
chlorides.

TEA SEED.

By DAVID HOOPER, F.G.S.

During the past year several notices have appeared
in agricultural papers with reference to the seed of
the tea bush and its probable uses in the arts, or for
domestic purposes. The price of tea seed some years
ago ranged from Rs. 100 to Rs. 200 per mand; now
planters would be glad to part with the article for
Rs. 40 to Rs. 10 for that quantity, and, indeed, with
some it is a waste product without any market value.
In Ceylon the planters have for some time been
trying to find a use for their surplus seed, but without
any apparent success. In Northern India, hundreds
of mannds of seed are going to waste on the bushes of
abandoned tea estates, and efforts have been made to
dispose of the seeds in Calutta and elsewhere.
Although we have not abandoned tea gardens in
Southern India at present, the seed is more easily
procureable than it was a few years ago, and no doubt
it could be supplied in quantity if there were any
demand for it. In 1885, some tea seed, under the
name of “Tanne,” was offered for sale in the London
market, and was regarded as a great curiosity, but it
met with no purchasers.

The oil from tea seed has been put forward in some
places as an article of considerable utility, but some
practical experiments in expressing the oil in this
country, and the unsatisfactory character of a few
authentic samples, have contributed to throw dis-
credit upon such a substance as a source of profitable
manufacture. The tea oil which has such a reputation
and is so largely used in China, is expressed from the

* ‘Pteromelines and Leucinamines.’ Vaughan and Novy.
seeds of *Camellia drupifera*, Lour., a different plant to the genuine tea bush. A similar oil is also obtained from the ornamental camellia of our gardens (*C. japonica*), and the sweet-scented *C. sesanqua*, both natives of China and Japan. The oil from the first of the above-named plants is called "Cha yan," or tea oil, and is largely used for illuminating purposes and for dressing the hair, and sells at a rate which is equivalent to 4d. to 6d. per pound.

Tea oil is obtained from the seeds by cold pressure, then the pulp is steamed and again pressed. The oil is of a light yellow colour and odourless, and leaves an unpleasant after-taste in the mouth if eaten. It remains clear at ordinary temperatures and has been recommended as a good lubricating agent for watch-makers, as it does not dry or clog fine machinery. The peculiar after-taste does not deter the Chinese from using it for culinary purposes, and it is probable that the scid substance is destroyed by the heat employed in cooking. The oil of Sesanqua, an allied plant, is said to have an agreeable odour, and is an article of some importance among the Celestrals for dressing the hair. Camellia oil is said to be something like olive oil in not containing much solid fat which would separate out at low temperatures. The seeds are considered poisonous, and the oil was used in old times by Japanese warriors to grease their swords. These oils are not obtained in sufficient quantity for export, although samples have occasionally been sent to England and the continent for valuation. The oil of the true tea seed (*Camellia theifera*, Griff.), grown in India, seems to be of the same nature as that used in China, as the reports of various experts have proved, but whether any further use can be made of the seeds it will be necessary to know the nature of the other constituents present. It will therefore be desirable to draw attention to what work has already been done by chemists in this direction, and then to sum up their results in the light of a detailed analysis of some waste Indian seed from a local estate.

Mr. Hugh McCullum, Hong Kong, made, in 1884, an examination of some seeds of the Chinese *Camellia drupifera*, and obtained some interesting results. He found the oil in the seed to reach 44 per cent. of the weight, and this oil had the appearance and colour of safflower oil, but the taste did not recommend it. The pressed cake contained 10 per cent. of a substance called saponin, which is widely distributed in the vegetable kingdom, and is used for its detergent properties. The soap nut (*Sapindus trifoliatus*) and the soap bean (*Acacia concinna*) of India yield saponin in considerable quantity, and are used largely by the natives for cleansing purposes. In China, the powdered residue of the tea seed is an article of commerce, and under the name of *Ocha-tnai-ping* is sold as a rough greyish powder for washing clothes and the hair. This powder, mixed with water, is also used by gardeners for destroying worms and grubs; and made into balls, it is thrown into rivers and tanks to poison fish. Saponin occurs in many other seeds used for fish poisoning, and is always recognised by its sweet taste, which afterwards becomes bitter and acrid and leaves a biting sensation in the throat for some time, and by forming a lather and froth with water, just like soap. Saponin has very poisonous properties, and is seldom used in medicine.

About twelve years ago tea cultivation was introduced into Brazil, but owing to the Chinese being unable to fulfil their contract, the trees grew up and fruited. Dr. T. Peckolt, of Rio Janeiro, took the opportunity to analyse the seeds and found in them 13 per cent. of starch, 1 per cent. of caffeine, and 7-5 per cent. of fatty oil. The amount of oil here is very low, and the presence of caffeine in the seed is rather remarkable as it has not been confirmed by other investigators.

*(To be continued.)*

**A DRAFT BILL.**

**INTITULATED AN ACT TO AMEND THE WEIGHTS AND MEASURES ACTS OF 1878 AND 1889.**

Whereas doubts have arisen as to the legality under the Weights and Measures Acts of 1878 and 1889 of the use by traders of metric weights and measures for the purpose of verifying merchandise intended for export to places outside of the United Kingdom of Great Britain and Ireland, and whereas the Board of Trade now possess standards of metric weights and measures as enumerated in Part II. of the Third Schedule of the Weights and Measures Act 1878, and the Board of Trade is already authorised to verify metric weights and measures intended to be used for the purpose of science and manufacture, and whereas it is expedient to remove the doubts which have arisen, be it enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords spiritual and temporal, and Commons in this present Parliament assembled, and by the authority of the same as follows:—

1. This Act may be cited as the Weights and Measures (Metric Amendment) Act, 1895.

2. That, on and after the passing of this Act, wherever the word "trade" occurs in the Weights and Measures Acts of 1878 and 1889, it shall be so construed as not to prohibit or penalise the use of metric weights and measures, verified by the Board of Trade or local authorities, by export traders.

3. The Board of Trade are empowered to verify all metric weights and measures submitted to them by the metric standards in their possession, and to apply thereto the verification stamp, even when such weights and measures are to be used for export trade purposes and subject to the application of the person or persons desiring verification, being accompanied by a declaration in such terms as may from time to time be considered necessary by the Board of Trade (Standards Department), that it is not intended to use the metric weights and measures so verified for any other purpose than those of export trade.

4. "Export trader," means a person engaged in trade with countries other than those included within the United Kingdom of Great Britain and Ireland. "Export trade," means all business involving the outward shipping of goods conducted between a person in the United Kingdom of Great Britain and Ireland, and any country outside thereof.
The Council Meeting.

After the minutes of the previous meeting had been read and confirmed last Wednesday, the President mentioned that he had received letters from the members of the Boards of Examiners, thanking the Council for their appointment. A letter acknowledging the Council's vote of condolence had been received from the family of the late Mr. Hooper. Mr. Abraham had also written in acknowledgment of the resolution passed on his retirement from the Council, and Mr. Rutherford Hill had written to thank the Council for increasing his salary as Assistant-Secretary.

On the motion of the Vice-President, seconded by Mr. Rymer Young, and supported by Mr. Martin, Mr. William Warren, who succeeded the late Mr. Hooper in the business carried on by him in Russell Street, Drury Lane, was unanimously elected a member of Council. The necessity for a larger proportion of members resident in London, in order to carry out the work of the Society, was mentioned by Mr. Cross as one of the reasons for proposing the election of Mr. Warren, while the evidence he had already given of his fitness for the position was a still further reason. The same views were expressed by Mr. Young and Mr. Martin.

In referring to the recent death of Professor Flückiger, the President spoke of the important work he had done in conjunction with Daniel Hunsbury, and of the great interest he had always taken in the proceedings of the Society, proposing that, on behalf of the members, an expression of condolence should be sent to the family. This was seconded by the Vice-President and carried unanimously.

The additions to the Society comprised sixteen pharmaceutical chemist members, four chemist and druggist members, sixty-two associates, and ninety-four students.

The report and recommendations of the Finance Committee, which were of the usual routine nature, were adopted without discussion.

On the recommendation of the Benevolent Fund Committee, three grants of fifteen pounds each, one of twelve pounds, and one of ten pounds, were ordered to be paid, the first three being for the candidates unsuccessful at the late election of annuitants.

In reply to a question put by Mr. Hilla, the Vice-President said that although only one case had been dealt with during the past year, and there is no present application for the benefits of the Orphan Fund, he hoped it would not be supposed there is no need of subscriptions to that Fund. He also mentioned the case of Mary M. Lewis, who was an unsuccessful candidate for admission to the Welsh School, though a large number of votes had been obtained for her, and he hoped she would receive further support next June, as that would be her last chance of election.

In connection with the report of the Library, etc., Committee, the President referred to the Barbados Pharmacy Act, sent by the authorities of the Colonial Office to the Council for consideration, as being the only matter calling for comment. As illustrating the completeness of this enactment, it was mentioned that it enforced the passing of a preliminary examination before admission as an apprentice, and an intermediate examination before the final qualification at the age of twenty-one. The contrast between those conditions and the inability at home to establish systematic pharmaceutical education in the mildest form, was spoken of as affording ground for regret from every point of view.

An application from the Sheffield Pharmaceutical Society for a grant in aid of the pharmacy school in that city was referred to the Library, etc., Committee for consideration.

The report of the examinations held in Scotland last October showed that on that occasion the passes in the qualifying examination amounted to 46.36 per cent. Only two candidates presented themselves for examination to become pharmaceutical chemists, and only one passed.

On the motion of the President, seconded by Mr. Harrison, it was resolved that the Law and Parliamentary Committee should be convened at an early date to consider the expediency of applying to Parliament for such further powers as may be deemed desirable. Referring to the Barbados Act mentioned above, the President said that much had yet to be done before the interests of the craft and of the general public are properly provided for, and before those connected with the Society could be placed in an equally favourable position.
in relation to each other. Questions relating to poisons, and other questions of no small difficulty relating to limited companies, have to be dealt with, and it was suggested that the present is an appropriate time for considering whether it is expedient to take any steps with that object in the coming session of Parliament, and what form they should take. If a general agreement can be arrived at as to the objects to be aimed at, it will be necessary to be prepared for making an effort either in this session or the next. Mr. HARRISON expressed a similar opinion as to the desirability of being prepared for taking advantage of any opportunity that may arise, and in any case he thought the resolution of the Council would show that it is alive to the exigencies of the time.

The PRESIDENT reported the receipt of a letter from the President of the General Medical Council announcing that it has been decided to issue a new edition of the British Pharmacopoeia, and stating that, among other means to that end, the Council had adopted the recommendation of its Pharmacopoeia Committee, that the Pharmaceutical Society should be invited to assist in the work. In pursuance of the resolution passed to that effect (see page 584), Sir Richard Quain invited the aid of the Society, and requested that the matter should be brought before the Council.

The nature of the assistance desired is specified in the resolution of the General Medical Council as comprising the obtaining of trustworthy statistics, first as to well-recognised non-official remedies which are in demand, and, secondly, as to those official remedies which appear to have become disused. In addition the Society is invited to nominate pharmacists who would be willing to serve on a Pharmaceutical Pharmacopoeia Committee, under the guidance of the Society’s Council, and, with its concurrence, to report to the Medical Council through the Pharmacopoeia Committee of that body.

The PRESIDENT mentioned that he had acknowledged the receipt of this communication, and expressed his conviction that the Council would be glad to assist the General Medical Council in any possible way in the production of the new Pharmacopoeia. At his suggestion, Sir Richard Quain’s letter was referred to the General Purposes Committee for consideration.

A letter received from Mr. Umney, as representing a special committee of the London Chamber of Commerce and the Drug Club, was mentioned by the President, as calling attention to the fact that, while it is unlawful to use any metric weights and measures, wholesale druggists receive, from foreign countries where the metric system is in use, orders for goods to be supplied in kilos., etc., and they have been in the habit of supplying goods in that way. Recently the London County Council has given notice that this practice must not be continued, and an effort is consequently being made to obtain authority in such cases to use weights and measures of the metric system. For that purpose a Bill has been drafted to amend the Weights and Measures Acts of 1878 and 1889 (see page 588) and the assistance of the Pharmaceutical Society was asked in support of the measure. In accordance with a recommendation of the General Purposes Committee, the President moved that the proposed amendment of the law should be supported, and this was unanimously agreed to.

The report of the General Purposes Committee gave particulars of the progress made with cases which have been placed in the solicitors’ hands, and the recommendation that proceedings should be taken in several other cases was adopted.

THE LAVOISIER CENTENARY.

The past year was the centenary of the death of Lavoisier, the great French chemist, who dealt the final blow to the phlogiston theory and went far towards establishing the science of chemistry upon its present basis. To commemorate the occasion a statue was erected at Bucharest, facing the new Institute of Chemistry near the University, and the Bucharest Society of Physical Sciences has published, in connection with its official organ, the discourse of Dr. Istriati, delivered on April 26 (May 8, N.S.), 1894, the actual anniversary of Lavoisier’s execution. This is now produced in a very handsome form, the text being in both Roumanian and French, in parallel columns. The work embodies a full account of Lavoisier’s life and times, and work, whilst numerous engravings embellish it, in addition to a fac-simile of the death warrant signed by Barrere, and another of Lavoisier’s handwriting. The remainder of the book is occupied by an essay on the past history of science in Roumania, and an account of the proceedings at the banquet held on the occasion of the centenary.

R. H. DAVIES FUND.

At a meeting of the Committee of the above fund, held on the 9th inst. at the house of the Institute of Chemistry, Bloomsbury Square, Dr. W. Russell, F.R.S., in the chair, it was reported that the subscriptions had reached a sum which, after payment of all expenses, left a balance of about £700 for investment. It was resolved to expend this sum in the purchase of an annuity for fourteen years, by which time the two younger sons of Mr. Davies will be of age. Mr. Bevan and Mr. Chattaway were appointed trustees, and the annuity will be administered by them for the maintenance and education of the sons. A statement of account, with the resolutions adopted at the meeting, will be sent to the subscribers as soon as the final arrangements have been completed.

METRIC WEIGHTS AND MEASURES.

In reference to the proposed amendment of the Weights and Measures Acts, mentioned at the Council meeting on Wednesday, we learn that a committee, consisting of Messrs. Francis Yates, J. C. Peasman, and Charles Umney, has been appointed by the Drug Club to watch the matter.
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.

Wednesday, January 9, 1895.

Present—

MR. MICHAEL CARTMIDGE, PRESIDENT.

MR. WILLIAM GOWEN CROSS, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bottle, Gostling, Greenish, Grose, Harrison, Hills, Martin, Martindale, Newsholme, Southall, and Young.

The minutes of the previous meeting were read and confirmed.

The PRESIDENT announced that letters had been received from the members of the Board of Examiners, thanking the Council for their appointments. He had also received a letter from the family of the late Mr. Hooper, thanking the Council for the letter of condolence recently sent, and a letter from Mr. Abraham in acknowledgment of the letter of thanks to him passed on his retirement: The PRESIDENT also read a letter from the Assistant-Secretary in Edinburgh, thanking the Council for the increase in his salary.

ELECTION OF A MEMBER OF COUNCIL.

The VICE-PRESIDENT proposed that Mr. William Warren be elected a member of Council in the place of Mr. A. C. Abraham, resigned. He felt sure that Mr. Warren was a gentleman who would very efficiently perform his duties, but he was mainly induced to oppose him because he resided in London. When he looked round the room, and thought of the distance which the gentlemen present—except the London members—had to travel before they could take part in the deliberations, he was strongly impressed with the necessity of having a fair proportion of London members ready to confer with the officials when occasion arose. Mr. Warren, during the short time he was on the Council, gave evidence of his fitness for the position, and he believed that if he had been better known to the members generally the mistake of his rejection at the election would not have been made.

Mr. Young, in seconding the motion, said he had the more pleasure in doing so as he was to some extent, perhaps, the unwitting cause of what had been alluded to as the mistake of Mr. Warren's rejection at the election. He had not been long upon the Council before he discovered that Mr. Warren was a very much respected and useful man, and that his removal was a distinct loss to the Council. Allusion had been made to the fact that the number of London members on the Council tended to diminish, and if this process were carried much farther it would throw a considerable quantity of additional work on the country members. Many members attended two or three times during the month, and he thought he was expressing the feeling of most of the country members in saying that the majority of them would be unable or unwilling to come more than the usual number of times. He believed this motion would meet with the unanimous approval of the Council.

Mr. Martin, as a country member who had a long distance to come, said he knew something of the wear and tear entailed on some of his colleagues in attending meetings. He had had the pleasure of working with Mr. Warren on the Council, and knew something of the good work he was capable of, and he was quite sure the Council would make a wise choice in reinstating him. Since he (Mr. Martin) had been a member of the Library Committee he did not think he had missed many of the meetings, if any, but it was evident to him that the principal part of the work had to be done by those who lived in or near London.

The PRESIDENT, in putting the motion, reminded the Council that Mr. Warren was the successor of the late Mr. Hooper, at the historic premises in Russell Street, Covent Garden.

The resolution was carried unanimously.

BOARDS OF EXAMINERS.

The PRESIDENT said a letter had been received from the Privy Council, formally approving the appointment of Examiners for the year 1895.

DEATH OF DR. FLECKIGER.

The PRESIDENT said it fell to his lot to report the death of another distinguished honorary member of the Society, Dr. Fleckiger. He and the late Daniel Hanbury were recognised as the two greatest authorities on materia medica in this country, and perhaps in the world. Their work in that direction, which had been very closely associated with the Society, was of a solid character, and was more interesting by reason of the Society being a voluntary one and not a State-sided institution. He felt sure that all the members, and especially those who felt an interest in science, would join in the expression of condolence he proposed should be sent to the family of their deceased friend.

The VICE-PRESIDENT seconded the proposition, which was carried unanimously.

DIPLOMAS.

The undermentioned, being duly registered as Pharmaceutical Chemists, were granted diplomas stamped with the seal of the Society:

- Alocok, James Elsworth.
- Dales, Edward.
- Durbin, Henry Eastman.
- Hoit, Alfred Henry.
- Hope, Richard.
- Ingall, Sidney Herbert.
- Marsh, Alfred Edward.
- Massey, Cecil.
- Moffat, Charles Dunwall.
- Moorhouse, Joseph Wm.
- Peach, Charles Wm.
- Pearce, John Hammond.
- Perkins, Catherine Susan.
- Pickering, Walter.
- Potter, Henry Arthur.
- Scott, George L.
- Taylor, Charles John.

ELECTION OF MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination, and tendered their subscriptions for the current year, were elected "Members" of the Society:

- Alocok, James Elsworth.
- Crouch, William Samuel.
- Dales, Edward.
- Davies, John.
- Durbin, Henry Eastman.
- Grieve, James.
- Hare, James Archer.
- Hoit, Alfred Henry.
- Hope, Richard.
- Humphrey, John Thurlbeck.
- Hunt, John Lambert.
- Marsh, Alfred Edward.
- Moffat, Charles Dunwall.
- Stephen, Charles.
- Taylor, Charles John.
- Thorpe, Albert.

- Sheffield.
- London.
- Louth.
- Newcastle Emlyn.
- Putney.
- London.
- Hexham.
- Southsea.
- Westhoughton.
- Colwyn Bay.
- Luton.
- Stoke Newington.
- Ventnor.
- Folkestone.
- Dartford.
Chemists and Druggists.
The following, who were in business before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Giles, Theophilus Ridgway ... Burnley.
Hughes, Evan Griffiths ... Manchester.
Judeon, Charles William ... Ripon.
Taylor, James Johnson ... Manchester.

ELECTION OF ASSOCIATES IN BUSINESS.
The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Barker, Arthur Brook .......... Heckmondwike.
Bately, Stephen Briggs ... Tottenham.
Bayley, Cornelius ... Walsall.
Bennett, George ... Bollington.
Bishop, Edward James ... Folkestone.
Blomfield, Francis Henry ... Grith.
Cheatham, George Richard ... Lathom.
Cox, George Frederick ... Lenton.
Gibson, George Shaw ... West Hartlepool.
Gilbert, Joseph Anthony ... Manchester.
Grayson, William Henry ... London.
Hall, Robert ... Manchester.
Middleton, Ambrose ... Nottingham.
Moorman, Charles Edgar ... Shanklin.
Paton, Joseph Brewster ... Sheffield.
Roberts, Arthur Henry ... Weymouth.
Roberts, Thomas John ... Ruthin.
Scroggie, John Henderson ... Lauder.
Thorp, Edward Frederick W ... Manchester.

Modified.

Holme, Henry Thomas ... Wallingford.

ELECTION OF ASSOCIATES.
The following, having passed their respective examinations, and tendered, or paid, as Students, their subscriptions for the current year, were elected "Associates" of the Society:—

Minor.

Adamson, William ... Bo'ness.
Alcockson, David A. Donald ... Coventry.
Allison, John R. Bilyard ... Retford.
Arrowsmith, G. Micklem ... London.
Barritt, Wesley ... Rotherham.
Bates, Sydney Lancaster ... Birmingham.
Bell, William Edward ... Bootle.
Benjamin, Joseph ... Ystrad Mynyr.
Brooks, Joseph ... Manchester.
Brownling, Kate Emma ... Weymouth.
Burge, William George ... St. John's Wood.
Burgess, Frederick William ... Wigan.
Chase, Henry John ... London.
Copley, William Dawn ... Long Eaton.
Dawney, Charles Benjamin ... Bristol.
Devereux, Arthur ... Beaconsfield.
Duffield, Henry David ... Colchester.
Evans, Thomas James ... Lichfield.
Gilmour, Andrew ... Burslem.
Hammond, Walter ... Louth.
Hay, William Fowlie ... Aberdeen.
Haythornthwaite, William ... Giggleswick.
Hughes, William ... Llandysul.
James, David Griffith ... London.
Jennings, Cornelius ... Birmingham.
Kingston, Walter Wright ... Barnley.
Kirkpatrick, James ... Taunton.
Kitley, Sydney ... Bath.
Matlack, Charles ... Carlisle.
Miller, Thomas ... Berwick-on-Tweed.
Ockwell, Edwin ... Cirencester.

Modified.

Palmer, Frank Hermann ... Hull.
Paterson, Andrew John Kidd ... Dundee.
Rogers, Frank ... Petworth.
Russell, John, jun ... Broughty Ferry.
Raxton, James ... Abroath.
Steede, Frederick George ... Darlington.
Taylor, Charles Ludlow ... Buxton.
Tully, Fred Harborton ... Corwen.
Williams, John ... Accrington.
Wilson, James Munro ... Auchinleck.

Rose, George ... Rolleston.

ELECTION OF STUDENTS.
The following, having passed the First examination, and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Anneley, Sara ... London.
Bain, Henry Robert ... Glasgow.
Battle, John Cyril Marlborough ... London.
Birnie, Alexander Stephen ... Aberdeen.
Bradford, John Finnie ... Liverpool.
Buchan, Andrew ... Edinburgh.
Castell, Guy John Edward ... Daventry.
Chambers, Ernest James ... Westminster.
Cherry, Frederick ... Bloxham.
Clark, Alexander Robertson ... Brighton.
Collie, Alexander ... Bellshill.
Coombe, Frank Ernest ... Sutton-in-Ashfield.
Coff, Sidney ... New Barnet.
Davies, John William ... Liangollen.
Davis, Oliver Charles Mynce ... Weston-super-Mare.
Dawson, Henry Gray W ... Derby.
Dawson, Wm. John Reynolds ... Wimborne.
Dickenson, Joseph Frederick Hyson Green ... Greenwich.
Durrant, George Stuart ... London.
Edes, Joseph Edward ... Tipton.
Edwards, William ... Bridgewater.
Finn, Francis Dudley ... Dover.
Fuge, Dingley Palmer ... London.
Giles, Frank ... Folkestone.
Giles, Lewis John ... Folkestone.
Griffiths, Francis ... Birmingham.
Griffiths, William Henry ... Widnes.
Hall, Harold William ... Thornes.
Hampton, William Henry ... Cheltenham.
Hankinson, Herbert Stanley ... Liverpool.
Hanson, Arthur ... Bingley.
Happold, Charles ... Barrow-in-Furness.
Harris, William Edward ... Kingston-on-Thames.
Hetherington, Vernon ... Winchester.
Hickman, Frederick Stanley ... London.
Hoare, William Harold ... Derby.
Hooper, Richard John ... Wood Green.
Huck, Harry ... Leatherhead.
Hutton, John ... Edinburgh.
James, William Alfred ... Acreby.
Jealous, Bernard ... London.
Jenner, Thomas William ... London.
Jones, George Gilbert Tudor ... London.
Kenney, George William ... Nuneaton.
Kerby, William Albert ... Southsea.
Krause, Harry John Godfrey ... Crimsby.
Lee, Arthur ... Louth.
Lenton, Walter Henry ... Thrapston.
Lowson, William ... Drifton.
Lyle, James Alexander ... Bradford.
Martin, Wilfred ... Romford.
Mason, Horace Dermocou ... Crawley.
Mastertone, Walter Ewart ... Lancaster.
Maunder, William Henry ... Telghmound.
Merry, Charles ... Johnstone.
Moore, Lucy Bramley ... London.
Mosley, William Francis ... Longton.
Nathan, Hyam ... Edinburgh.
Restorations to the Register.
The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:

- Slater Lupton, 5, Bristol Road, Weston-Super-Mare.
- Edwin Morris, St. Peter's, Kent.

Several persons were restored to their former status in the Society upon payment of the current year’s subscription and a restoration fee of one shilling.

This report was of the usual character, recommending sundry accounts for payment.

The President, in proposing its reception and adoption, said it was of an ordinary character, and called for no special remarks. The receipts were of the character usual in December, and the payments were of the kind expected at this time of the year. The Benevolent Fund account, included the usual ground rents, out of which had been paid the interest on the money lent by the Orphan Fund. In the absence of a sufficient sum to invest, or an opportunity of investing it, in ground rents, this was found a convenient way of employing the money in hand on the Orphan Fund account. The receipts included a curious one, viz., 10s., representing the value of the assets belonging to the Hawick Society. After paying the expenses of what he might call its funeral, this 10s. was left, and had been sent for the Benevolent Fund.

The report was adopted.

Benevolent Fund Committee.
The report of this Committee included recommendations of the following grants:

- £10 to the widow (89) of a registered chemist and druggist with three children of her own, aged 7, 5, and 2½ years, and three older step-children, dependent or partially dependent. (Edinburgh.)
- £12 to the widow (85) of a member and subscriber (1848–1868) who has had four previous grants, amounting to £42. (Dorchester.)
- £15 each to the unsuccessful candidates at the election of annuitants in December last.

Four cases were not entertained.

The Committee recommended a verbal alteration in regulation 10 to the effect that candidates’ votes for past subscriptions or donations shall be placed to their credit at “each election during his or her candidature,” instead of “at the first succeeding election.”

The President explained the nature of the proposed alteration in the regulation as being designed to meet what might be a misapprehension. It really only formally directed what now actually transpired in respect to the matter.

The Vice-President then proposed the reception and adoption of the report; and on being put to the meeting it was carried unanioumously.

The Orphan Fund.
Mr. Hills asked had any application been received for the benefit of this Fund during the last twelve months?

The Vice-President said they had only dealt with one case; but he hoped this would not be taken as an indication that they had no real work before them and no need of subscriptions, and even of enlarged subscriptions to the Orphan Fund. These cases frequently came before them, not singly, but two or three together, and they usually required to be promptly dealt with. He trusted, therefore, that subscriptions would be well maintained, and the Fund kept in an efficient state. In this connection he might mention that he had received a letter from one of their members calling his attention to the case of Mary M. Lewis, whom they supported at the last election to the Welsh school at Ashford. Although she was unsuccessful, she managed to poll 298 votes, but more than that number, he feared, would be required if they were to carry her in at the election next June, which would be her last chance. He had received support from several gentlemen, and should interest himself in the case. He would ask any member acquainted with a governor to be good enough to exert himself to secure his support, the more so as they unanimously agreed on the last occasion the case was before them, that it was in every way one well worthy of their support.

Library.
The report of the Librarian had been received, including the following particulars:

<table>
<thead>
<tr>
<th>Month</th>
<th>Total Attendance</th>
<th>Highest</th>
<th>Lowest</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>November</td>
<td>605</td>
<td>32</td>
<td>14</td>

<th>Total Circulation of Books</th>
</tr>
</thead>
<tbody>
<tr>
<td>November</td>
<td>253</td>
</tr>
</tbody>
</table>

Donations to the Library had been announced (Pharm. Jour., December 12, p. 506), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the undermentioned works be purchased:
For the Library in London—
Crookes, Select Methods in Chemical Analysis, 3rd ed.
Thorpe, Essays in Historical Chemistry.
Remington, Practice of Pharmacy, 3rd ed.
Pharmacognosy Collin, Les Drogues Simples d'Origine Végétale.
Wurtz, Dictionnaire de Chimie, deuxième supplément.
Griffith, Flora of Anglesey and Carnarvonshire.

Museum.

The Curator's report had been received, and included the following particulars:—

<table>
<thead>

<td>61</td>
<td>10</td>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>

Donations to the Museum had been announced (Pharm. Jour., December 15, p. 506), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

Letters of thanks had been received from the Director of the Science and Art Museum, Dublin; the Professor of Materia Medica and Pharmacy at the Royal College of Surgeons, Ireland, for donations of materia medica specimens; from Professor Pensig, of the Hanbury Institute, Genoa, and the lecturer on materia medica at Oxford, for herb-barium specimens; and from the Botanic Gardens of New, Edinburgh, and Oxford for specimens of seeds.

The School Staff attended and reported.

The President had reported that he had carefully considered the copy of the Barbados Act, which had been sent by the Marquis of Ripon for the observations of the Council, and it was decided that a suitable letter should be sent to the Colonial Office, expressing approval of the enactment.

Pharmacy Law of Barbados.

The President, in moving the adoption of the report, said the only matter calling for comment was the Barbados Pharmacy Act, which had been referred to the Committee for consideration. He could only say that the Committee was much impressed with the completeness of this enactment. Whilst they at home were in the helpless position of not being able to impose the mildest form of curriculum or puillage as an introduction to pharmacy, in Barbados the new law enacted that it should be unlawful to take a pharmacetical without passing a preliminary examination. Then he had to pass an intermediate examination before he was twenty-one, and finally, on reaching that age, he had to pass a further examination. Concurrently the privileges conferred on pharmacists were much greater than those enjoyed in the mother country. It was very satisfactory to see such an advance made in one of the dependencies of the Crown.

The influence of education and the regard paid by medical men to the importance of having educated chemists and druggists appeared to be so great that they had apparently no difficulty in getting a satisfactory Pharmacy Act, which would not only tend to promote higher education but would confer far greater safety on the public than was the case in this country. He could not help feeling some regret that hitherto all the efforts made in this direction had but prepared the way for their brethren in various parts of the world, no serious endeavour on the part of the great mass of the trade at home having been made to take these matters into their consideration.

Mr. Atkins remarked that the colonies were free from the monopolies and vested rights which often stood in the way in old countries.

The resolution for the adoption of the report was then agreed to.

Sheffield Pharmaceutical Society.

The President said a letter had been received from Mr. George Square, secretary of the above Society, asking for a grant of £50 towards the expenses of the local school of pharmacy, and enclosing a balance sheet. He proposed that the application be referred to the Library, Museum, School, and House Committee.

This was agreed to, and a similar application from Inverness was also dealt with in the same way.

Mr. Martin said he presumed the assistance was asked, not to meet current expenses of the school in question, but to provide apparatus, books, or something of a permanent nature.

The President said that was the principle on which the Council had acted hitherto in dealing with such applications.

Revision of the British Pharmacopoeia.

The President reported the receipt of the following letter:—

"General Council of Medical Education and Registration of the United Kingdom.
299, Oxford Street, London, W.
December 12, 1894.
"To the President of the Pharmaceutical Society of Great Britain.
"Dear Sir,—The General Medical Council has decided to issue a new edition of the British Pharmacopoeia. Amongst other means to this end, the Council has unanimously adopted the following recommendation of the Pharmacopoeia Committee:—
"The Committee, remembering the valuable assistance given to the Medical Council by the Pharmaceutical Society of Great Britain in the production of the Pharmacopoeia Addendum of 1890, recommends that the invitation to that Society to assist in the compilation of a new edition of the Pharmacopoeia be now forwarded, first as regards the obtaining of trustworthy statistics respecting well-recognised non-official remedies which are in demand, and respecting those official remedies which appear to have become disused, the Society being invited to reply before the end of March, 1895. Further, the Committee recommends that the Council of the Society be invited, as heretofore, to appoint a pharmacopeia Committee under the guidance of the Society's Council, such Committee finally reporting, with the concurrence of the Society's Council, to the Medical Council through the Pharmacopoeia Committee of the Medical Council.
"I have, therefore, the pleasure of inviting the aid of your Society in the directions above indicated, and of asking you to bring the matter before your Council at an early date.
"I am,
"Yours faithfully,
"(Signed) Richard Quain.
"President of the Medical Council."

He had, of course, acknowledged the receipt of this communication, and felt sure the Council would be glad to assist the General Medical Council in every possible way in the production of their new work. It seemed to him the proper course would be to refer the letter to the General Purposes Committee for consideration and report.

That course was accordingly agreed to.

New Publications for the Library.

The President said a letter had been received from the Under-Secretary of the Department of Mines and Agriculture in New South Wales, saying that on
the suggestion of Mr. Maiden (a corresponding member of the Society), the Agricultural Gazette published by the Department would be forwarded regularly to the Pharmaceutical Society as issued.

Mr. Martin suggested that the monthly journal of the Imperial Institute, which was being published, should be obtained for the library.

**GENERAL PURPOSES COMMITTEE.**

The report of this Committee included the usual letter from the solicitors stating the progress made with their hand in the various cases, and that several defendants had paid penalties and costs without going into court, and a few cases were awaiting trial.

Several cases of infringement of the Pharmacy Acts were reported to the Committee, and proceedings were recommended.

A communication had been received from Mr. Charles Umay, with regard to the use of metric weights and measures, and enclosing a draft bill which had been prepared by a sub-committee of the London Chamber of Commerce. This was hoped would receive the support of the Council. The Committee recommended that the Council take such steps as were necessary in favour of the Bill.

The Committee recommended that the Law and Parliamentary Committee be convened at an early date to consider the expediency of applying to Parliament for further powers as might be deemed expedient.

**Proposed Amendment of the Pharmacy Acts.**

The President said he would propose a resolution "That the Law and Parliamentary Committee be convened at an early date to consider the expediency of applying to Parliament for such further powers as might be deemed desirable." He had just referred to the excellence of an Act passed for Barbados, and he might refer to the fact that there was a good deal yet to be done with regard to education, training, and various other matters, before the members and representatives of the Society were placed in an equally favourable position, not only as regards their relation to each other, but as to the interests of the crafts and the public at large. There were many questions connected with British postal law to consider, and others of no small difficulty connected with company and corporation trading, which came under the notice of the Council from time to time, and it seemed to him that it would be an appropriate time—at the commencement of a new session of Parliament—for them to consider it expedient to take any steps whatever in the coming session, and, if so, to report in the form of a draft Bill what it was considered advisable to go for. He could not say that he was very sanguine as to the possibility of accomplishing anything, but one never knew what might happen. Sometimes, when there was a probability that Parliament might be dissolved at the end of the session, Government business was disposed of pretty promptly, and an interval remained in which some private business might be got through. He was not unconscious of the difficulty of getting such a considerable number of the House of Commons, in the present somewhat excited condition of affairs, to give their attention to pharmaceutical matters, but he did believe that, if something like a general agreement could be arrived at as to what should be aimed at, it would be desirable either in this session or in the next to make an effort at legislation. With this view he brought forward the motion, and he hoped that one meeting of the Committee, at any rate, might be held before the next Council meeting.

Mr. Harrison, in seconding the motion, said he did not propose to occupy time by enlarging upon it, because at this stage it was quite unnecessary. The terms of the motion implied that they were not pledged to any special Bill, or even to going for a Bill at all, but simply that the Committee should consider whether it was expedient to go to Parliament at all, and, if so, for what. Of course, the Committee, which was large, and had now been in existence for a time, had considered the various grievances under which the craft was labouring, what remedies might be applied, and whether the time had not come when an attempt should be made to incorporate those remedies in an Act of Parliament. It was impossible to say what could or could not be done in the coming session. It might be that there would be a sort of truce in the more active opposition, which had been going on for some time, before an appeal was made to the country, and that during that time some useful and quiet legislation affecting the well-being of the country at large might be got through, or, again, it might not, but at any rate the proposed resolution would show that they were alive to the exigencies of the times, and were prepared to act if circumstances were favourable.

The resolution was carried unanimously.

**Metric System of Weights and Measures.**

The President then referred to the receipt of the letter from Mr. Umay, who was a member of the Council of the London Chamber of Commerce, with regard to drugs, and also the Drug Club, calling attention to the fact that it was unlawful, even for wholesale druggists not less than retailers, to use any metric system of weights and measures. As they knew, from South America and many French-speaking colonies, orders were sent in kilos, and it had been the custom to weigh and dispatch by kilos. In the wholesale drug trade, but a London County Council inspector had recently called on one of the largest wholesale drug houses in the City, and cautioned the firm to continue their use no longer, although he said they might, if they pleased, in the place of the kilo, put on their scales the equivalents in British weights. That could not be easily or satisfactorily done. An effort was accordingly to be made to alter this state of things, and a Bill had been drafted to that end, amending the Weights and Measures Acts of 1878 and 1889. This would be backed by Sir Albert Rollitt, Sir Samuel Montagu, Sir Bernard Samuelson, and Mr. Mundella. It would consist of only three clauses, and its object was to make such an alteration in the law as would allow the export trade to use French weights and measures, of course duly stamped and authorised. Mr. Umay had asked the Society's support in the matter, and the communication was received in time to bring it before the General Purposes Committee, which yesterday considered the subject, and unanimously decided to recommend the Council to support a resolution in favour of the proposed amendment of the law. He would, therefore, move a resolution to that effect.

The motion was unanimously agreed to.

After dealing with the latter portion of the report of the General Purposes Committee by the specific resolutions recorded above, the Council went into committee as usual to consider the legal portion. On resuming, the report was adopted, and a formal resolution passed authorising proceedings being taken against the persons named therein.

FIRST EXAMINATION QUESTIONS.
January 8, 1885.

LATIN.
Time allowed—From 11 a.m. to 12:30 p.m.

1. (For all Candidates.) Translate into Latin:—
   1. I have seen the son of the man himself.
   2. The sun is greater than the earth, but the moon is smaller.
   3. It is true that the slave has been punished by the master.
   4. Having taken the camp, they departed.
   5. I fear you do not know what you ought to do.
   6. Translate into English either A (Caesar) or B (Virgil).
   (Candidates must not attempt both authors.)
   A. CAESAR.

   1. Quam ab his saepius quereret, neque ullam omen
   vovem exprimere posset, idem Divitisces Aedus
   respondit: Hoc esse misierorem et gravierum fortunam
   sequarum quam reliquorum, quod solet in oculos quidem
   quemque saeulit implorare,
   absensaque Ariostrum credibiliter, velit si coram
   adesse, horrorem; propterque quos reliquis tamen
   fugias facultas dareat, Sequianus vero, qui intras
   fines suos Ariostrum receptaret, quorum oppida
   omnia in potestate ejus essent, omnem cruciatus essent
   preferendam.
   2. Qui se ex his minus timidos existimari volebat,
   non se hostem vereri, sed angustias itineris et magni
   tudinem aliarum, quae inter eos atque Ariostrum
   intercederant, aut rem frumentaria, ut satis com-
   modo supportari possit, timere dicerant. Nonnulli
   eisam Cassari remulcantes, quum osaer moveri a
   signis ferri justiset, non fore dicto audentes milites,
   neque proprii timorem signa lastrup.

   Grammatical Questions.
   (For those only who take Caesar.)
   1. Decline, in the singular, meus fratris; and, in the
   plural, felix magister.
   2. Write in Latin 17, 96, 19th, twice, three each.
   3. Give the principal parts of regor, possum, fero, fes,
   eo, fero, facio, sequor.
   4. Give, with the English, six Latin words which
   have different meanings in singular and plural.

   B. VIRGIL.

   1. Id metuemus, veterisque memores Saturnia bellis,
   Prima quod ad Trojanum pro caris gesserat Argis—
   Necudm etiam causae irarum saevique dolores
   Exsiderant animo. Manet alta mente repostum
   Judicium Paridis, spretaeque injuria formae,
   Et genus invisum, et rapti Ganymedis honores.
   2. Parte aliena fugiens amissis Troilus armis,
   Infelix puer, atque imper congressus Achillis,
   Furtur equis, curruque haeret rupeus spinis,
   Lora tenens tamen; huo ovariqve conseque
   trahuntur
   Ver terram, et versus pulvis insoribitur hasta.
   Interes ad templum non aequae Paladis ibant
   Cribus illades passis, peplumque ferebant
   Superpliciter tristes, et tussae pectoris palmis.
   Diva solo fixos oculos averse tenebat.

   Grammatical Questions.
   (For those only who take Virgil.)
   1. Decline, in the singular, meus fratris; and, in the
   plural, felix magister.
   2. Write in Latin 17, 96, 19th, twice, three each.
   3. Give the principal parts of regor, possum, fero, fes,
   eo, fero, facio, sequor.
   4. Give, with the English, six Latin words which
   have different meanings in singular and plural.
**Arithmetic.**

Time allowed—from 12.30 p.m. to 2 p.m.

[The working of these questions, as well as the answers, must be written out in full.]

1. How many more square inches are there in 5 square miles 3 acres 3 yards than there are ounces in 2222 tons? (Answer in words.)

2. Divide $11\ 1s. 6d.$ by $3\frac{1}{2}$ and multiply the quotient by $\frac{3}{4}$ of $\frac{9}{4}$.

3. Simplify $(1\ 05-1\ 05) + (1\ 25 - 1\ 0625)$.

4. A person after paying 7s. in the £1 for income tax has £239 10s. left. What was his gross income?

5. Write down the English and French measures of Solidity. Give approximately the English equivalents of a mètre, a kilomètre, a kilogramme, a hectare, a litre, a stère.

6. An article which cost 19 guineas per cwt. is resold at 4s. 6d. per lb., and there is a waste of 5 per cent. What is the gain per cent.?

7. Find the price of 4½ per cent. stock when an investment of £609 ¾ produces an income of £42 15s.

---

**English.**

Time allowed—from 3 p.m. to 4.30 p.m.

1. Analyse:

   "Thrice is he armed that hath his quarrel just;

   And he but naked, though locked up in steel,

   Whose conscience with injustice is corrupted."

2. Parse fully:

   Thrice, that, but, though, locked. (Question 1.)

3. Correct the following sentences, giving your reasons:

   (i.) My older brother is two inches taller than me.

   (ii.) This boys' bottle is fuller than that boys'.

   (iii.) He has brought this memoranda, and not before it was wanted, either.

4. In the following passage supply the necessary capital letters, and put in the stops and inverted commas where necessary:

   "it is said that the night before they were to pass into Macedonia brutes was sitting alone in his tent when he saw the figure of a man before him who art thou he asked and the answer was i am thy evil genius brutes i will meet thee again at Philippi."

5. Write a short composition on one of the following subjects:

   (i.) The good and harm of newspaper reading.

   (ii.) The importance of the study of hygiene.

   (iii.) A country drive or walk in winter.

   (iv.) "Use lessons marverful."

---

**Parliamentary and Law Proceedings.**

**Proceedings Under the Sale of Food and Drugs Acts.**

The Sale of Seditious Powders.

On Saturday, December 29, at the Halifax West Riding Court, Albert Crabtree, manager of the Luddendenfoot Co-operative Society's Stores, was summoned for selling seditious powders "not of the nature, substance, and quality demanded." Mr. Hankinson, of Wakefield, who prosecuted, called evidence to show that the same purchase had been certified by the West Riding analyst not to contain the constituent portions of bi-carbonate of sodium and tartaric acid prescribed by the British Pharmacopoeia. In defence, it was shown that the powders were purchased from a dealer in Preston, who holds a guarantee as to their genuineness. A fine of 20s. and 10s. 6d. costs was imposed.—Bradford Observer.

* This must be attempted by every candidate.

---

**Poisoning Cases and Inquests.**

Poisoning by Hydrocyanic Acid.

Dr. Charles John Kirwan, a retired army surgeon, aged 65, died on Wednesday, December 19, at Dublin from the effects of hydrocyanic acid. Verdict: "Deceased committed suicide by drinking half an ounce of hydrocyanic acid while temporarily insane."—Irish Independent.

Poisoning by Caustic Soda.

Norman Smith Whittaker, aged 21 months, son of Mr. John Whittaker, manufacturing chemist 443, Blackburn Road, Accrington, died on Tuesday, December 18, from the effects of drinking a solution of caustic soda, which brought on ulceration of the throat and bowels, and caused inability to take food.—Accrington Observer.

Poisoning by Morphine.

Frederick Stevens, aged 27, died in the Highgate Infirmary, of the Holborn Union, on Tuesday, December 18, from the effects of morphine, which deceased used to inject into his arms. Verdict: "Death from the effects of morphine poisoning whilst suffering from bronchitis."—Morning.

Poisoning by Carabolic Acid.

Everest Fellowes, a native of Tarracena, Holland, died on board the steamship Halstead, at the Victoria Wharf, Limehouse, from the effects of carabolic acid, and an inquest was held on Monday, December 24. Verdict: "Suicide whilst temporarily deranged."—Star.

Poisoning by Morphine Hydrochlorate.

John Norman Cawthorne, aged five months, died at Sunderland, on Thursday, December 27, from the effects of morphine hydrochlorate, which was administered in mistake for magnesia by his mother. Verdict: "Accidental poisoning."—Sunderland Herald.

Poisoning by Hydrochloric Acid.

Harriet Rosehill, aged 35, died at 33, West India Dock Road, E., on Wednesday, December 26, from the effects of hydrochloric acid, self-administered. Verdict: "Suicide whilst of unsound mind."—Morning Leader.

Poisoning by Laudanum.

Dr. Charles Sibley Hicks, aged 33, died at Eyam on Thursday, December 20, from the effects of laudanum self-administered.—Nottingham Daily Express.

Poisoning by Oxalic Acid.

Edward Miles, about 37 years old, died at Exning, on Saturday, December 22, from the effects of oxalic acid, self-administered. Verdict: "Suicide whilst in an unsound state of mind."—East Anglian Daily Times.

Poisoning by Laudanum.

Frances Eleanor Ottignon, aged 56, died on Saturday, December 29, at 132, Junction Road, Upper Holloway, from the effects of laudanum, self-administered. Verdict: "Suicide whilst of unsound mind."—Daily Chronicle.

Poisoning by Carabolic Acid.

Caroline Rankin, aged 83, died on Monday, Dec. 31, at 27, Hayford Avenue, South Lambeth Road, London, from the effects of carabolic acid, self-administered. Medical evidence was given at the inquest showing that death was due to shock from carabolic acid poison. Verdict: "Suicide whilst of unsound mind."—Evening News and Post.
DEATH FROM AN OVERTOXICITY OF CHLORODYNE.
George James Ferrott died at Shildon, on December 30, from the effects of an overdose of chlorodyne, taken as a remedy for insomnia. Verdict: "Death was due to misadventure, by the taking of an overdose of chlorodyne."—Edinburgh Evening News.

POISONING BY PRUSSIC ACID.
Charles Whitefield, a surgeon, aged 63, died at 5, Lower Castle Street, Bristol, on January 1, from the effects of prussic acid. Verdict: "Deceased died from the effects of prussic acid, self-administered during a fit of temporary insanity."—Western Daily Press.

DEATH FROM AN OVERTOXICITY OF LAUDANUM.
David Crea, aged 32, died at 38, Gladstone Street, Widnes, on Thursday, January 3, from the effects of an overdose of laudanum. Verdict: "Death from misadventure."—Liverpool Mercury.

POISONING BY OXALIC ACID.
Isabella Bone, aged 56, was found lying in a state of unconsciousness on the Albert Embankment, London, and was removed to St. Thomas's Hospital, where she died on Saturday, January 5, from the effects of oxalic acid poisoning. Verdict: "Suicide during temporary insanity."—People.

Reviews and Notices of Books.

AN INTRODUCTION TO STRUCTURAL BOTANY. By D. H. Scott, M.A., Ph.D. Pp. i-xii., 1 to 288, with 113 figures, 3s. 6d. London: A. and C. Black.

The great development of botanical science in recent years has led to great modification of the views held by the older botanists of the fundamental principles underlying vegetable structure. In consequence of this it has become increasingly difficult for teachers to educate their students in the subject; the ordinary elementary text-books containing so much that either needs modification or correction in the light of the new work. The difficulty that besets the ordinary learner is even greater, his text-book and his teacher seeming to be at variance. Nor has the introduction of the type system as presented by the works on elementary biology met the difficulty. In them the student finds presented to him a number of forms with a certain sketchy outline of their respective life histories, but put before him in such a way that he fails to appreciate the connection or relationship between them.

The need for a new kind of elementary text-book of botany has thus become pressing, and the one before us is written with the view of supplying that want. In it Dr. Scott sets out with the idea not of presenting to the student a comprehensive view of the whole subject, but of putting forcibly before him the structure and life work of representatives of the leading classes of the vegetable kingdom. With this view he has elected to work upon the type system, but he has approached it from a different side to the writers of the so-called text-books of biology. At the outset he puts very prominently before the tyro the fact that he is about to study a living being, whose form and structure can best be explained by examining its habits of life. The physiological meaning of the outward form and the internal structure thus serves as the basis of the study. The advantage of this method of treating the subject is obvious. The student need no longer lose himself in the old dry detail which used to go under the name of botany. The terms used are explained and illustrated as the need for their employment arises.

Dr. Scott begins his introduction to the subject by telling his reader to begin his work by an actual examination of a simple plant, accessible to everyone—the common wallflower—and he makes the study essentially a practical one, the plant and the textbook being used together. The student is first led over the external features and then taken to the more difficult details of the internal structure. In this way the vegetative and reproductive characters are successively examined and the life history is illustrated. This having been mastered, the next section of the work describes simply and lucidly the processes of development by which the structures are produced.

Two other types are dealt with in the volume, the lily and the spruce fir. Each is examined with sufficient minuteness, and then careful comparisons of the three types are made. A further section deals in more detail with the physiological processes which all alike carry out. The author must be heartily congratulated on the new departure he has made in the direction of botanical teaching. He intimates that the present volume is likely to be followed by another, treating in a similar way with the lower forms. This new volume will be eagerly looked for by the students who work intelligently through the present one.

The fifth edition of this book contains chiefly forms for special preparations used in the treatment of throat diseases. The pharmacy of the book is well done, and shows evidence of practical and careful supervision except that in a few cases names of preparations contained in the British Pharmacopoeia have been appropriated for preparations of different composition, e.g., mistura cretis, unguentum potassii fodi, and vapor chlorii. The introduction of a number of "nosetrump preparations," of which "fumus himrod" and collunarium hasselin" are examples, is also an unsatisfactory feature from a pharmaceutical point of view, and has been often enough condemned by medical authorities.

An introductory paragraph is given at the beginning of each set of special formulce, describing their uses and modes of application. Nasal bougies and douches, gargles, medicated cotton wools, ear-drops, insufflations, pastils, and spray, fuming, hot, cold, and dry inhalations, are the chief classes of preparations so treated. The pastils are practically lozenges, of the kind known popularly as jujubes, made with a basis of glyco-gelatin coloured with carmine, and are specially useful in inflamed conditions of the mouth and throat when the medicinal agent is not incompatible with gelatin. Working formulce are also given for the well-known T.H. lozenges made with a basis of fruit paste.
instead of sugar. The book will no doubt serve as a reliable and useful guide to the medical practitioner, in suggesting the best means of applying remedies for treatment of diseases of the throat and neighbouring organs.

This useful little work has now reached its fifth edition, and, as usual, gives full information in a concise form respecting all the newer aids to therapy. Amongst the more recent additions are articles on algin, alhol, antipyrin, bromethylformin, catherin, acid, chloralose, crystalline, diphenyl, diltidiform, ferratin, guassol, iodiform, gallates of mercury, glycerophosphates, glycosone, lodiformine, iodide of rubidium, lung extract, medicated milks, loretin, lyophil, manacid, naphthol dithiol, paraform, resol, salacetol, salolin, serotherapy, sodium chlorate and sulphocarinate, tannin, thermodin, thioform, vasogenic, etc. A large number of plants recently introduced into medical practice, and not as yet described in any formulary, are also dealt with. The book will prove invaluable to every up-to-date pharmacist who is acquainted with the French language.

Books, etc., received.

Notes and Queries.

HABENDA RATIO VALETUDINIS. [789.] "Will you kindly let me know the literal and free translations of the motto Habenda ratio valetudinis?—STUDENT.

The literal meaning of ratio is the art or mode of thinking; habenda is the gerundive of habere, the literal meaning of which is "ought to be had." Ratio depends entirely on the context for its significance—without reference to context no opinion as to its true translation is of any value. When in combination with habère or ducère, it means to have a care for, or regard, or consideration for—[a noun in the genitive case]. Habenda ratio valetudinis means literally "a care of health ought to be had," and in good English, "It is our duty to care for health."

PHENYLHYDRAZONE TEST FOR GLUCOSE. [790.] "I find some difficulty in the use of this test, which has been spoken of very highly by Sir G. Johnson.—G. PONTHIEU.

This test depends upon the formation of phenyglycoseone (C8H5.-H2N.O). When an aqueous solution of phenylhydrazine hydrochloride and sodium acetate is added to a strong solution of dextrose, and the mixture is heated on a water-bath, a yellow precipitate of needles, singly or in bundles, of phenylglycoseone begins to form in a few minutes. In dilute solutions the crystals form more slowly. After an hour and a half the precipitate is said to amount to 85-90 p.c. of the weight of dextrose present. The crystals are purified by recrystallisation from alcohol, and should have a melting point of 204°-205°. Since decomposition commences at this temperature, the determination should be made quickly.

INK FOR WRITING ON GLASS. [791.] The following formula is said to yield a satisfactory ink for writing on glass, which is not affected by water:—White lao, 10 parts; Venice turpentine, 5 parts; oil of turpentine, 15 parts; indigo in powder, 5 parts. The first three ingredients are melted together on a water-bath, and the indigo is then added (Neuete Erfindungen und Bull. de pharm. de Bordeaux).

BORO-SALICYLIC GLYCEROL. [792.] The formula for this preparation (see ants, p. 434), as employed by M. Jaudon, is as follows:—Mix boric and salicylic acids, each 10 Gm.; distilled water, 10 Gm.; glycerin, 40 Gm. The mixture is then heated to ebullition, after which calcined magnesia, 1 Gm., is added, and the whole of the water evaporated at a gentle heat. The glycerin used should be of such strength that, on cooling, the glycerole should measure 50 C.C., and each 5 C.C. will then contain boric acid, 1 Gm., and salicylic acid, 1 Gm. (Répertoire).

PPIPERAZINE. [793.] "I shall be glad if anyone can inform me of a better way of providing for the deliquescent character of pipperazine ordered in five-grain powders than by dispensing it in 1-drachm bottles?—W. N. G. L."
Correspondence.

THE REMUNERATION OF THE PHARMACIST.

Sir,—It has frequently been a topic of considerable interest and discussion among chemists as to how to meet the changed condition of their surroundings, when they are introduced into a neighbourhood heretofore free from such competition, by some of the now far too numerous drug stores locating themselves, and proceeding to announce with the most unblushing effrontery that they are prepared to dispense medicines, etc., at about one half the usual charges. Such establishments usually commence with a great distribution of handbills and price lists, scattered without stint throughout a large area. They also make the most reckless statements concerning themselves and their older-established neighbours, and without doubt a great deal of anxiety has often been occasioned to those who felt they might be seriously affected and prejudiced by such highly improper and unprofessional conduct. Various remedies have been recommended and tried in different localities; in some cases prices have been reduced by all the neighbouring pharmacists, in others by a few only, though in many, probably the large majority, the older-established chemist of repute, and with a personal connection to sustain him, has not been driven to alter the honourable and well-tried mode of conducting his business.

As to the best way of meeting the difficulty, it is obvious that no one mode of procedure can be advanced as being suitable for all cases. Each one must, of necessity, be considered and treated in the light of the special circumstances surrounding it, but I am strongly of opinion it is not desirable, as a rule, for the pharmacist to attempt to follow his "cutting" neighbour, and I am fortified in this opinion by the experience gained from a considerable and extensive point of view. Numerous cases are on record where the attempt to reduce prices all round in the very limited business of a chemist has entirely and ignominiously failed, and the bankruptcy court has sometimes been the last resort of the ill-advised and unfortunate individual who commenced it. But it does not follow therefore that it is not desirable, in some cases, to meet the wishes of patients and customers who desire by ready-money payments to obtain the advantage of a reduced charge or a discount. Indeed, there is abundant evidence that many families do not wish to change their chemist, and are content and satisfied if he will make some advance on the lines indicated towards meeting their wishes. A great many of the public do know and recognise that it is far more important to have a reliable and honourable man to prepare their medicines at a fair and not exorbitant charge, than, for the sake of a few pence, to run the risk of getting something inferior or less carefully prepared; and when the facilities which the pharmacist usually gives for obtaining medicines at any time are further borne in mind, it should be conceded that he deserves more than a mere trade remuneration.

But further experience now shows that while at first, for a longer or shorter period, the new man who introduces "cutting" prices apparently succeeds in doing a considerable business, yet he is far more liable to see that business vanish than the man who, slowly but surely, has built up a more solid connection. It is not too much to say that in more than one prominent example a business started and conducted on the "flaming" principle, while injuring the adjacent pharmacists, has done no real or permanent good to its owner, who therefore has the double mortification of having injured his neighbour and done no good to himself. One does not envy such person the remorse any honourable man must feel under such circumstances. On the whole, therefore, I believe the best way of acting is to make some concession to those who desire it, on the lines previously referred to, and, in addition, for the pharmacist to make his own preparations and guarantee their purity and efficacy. If he at the same time is quick to recognise that the public likes to try new inventions, and if he does not rely too much on old-fashioned and out-of-date preparations, there is no reason why a very considerable business cannot be done in the most legitimate manner. This plan has the immense advantage of securing to himself the sale of the articles he prepares, and, of course, the prevention of anyone undercutting the same. The last point is that, if the young gentlemen who are the assistants of to-day would carefully consider that by giving their services to stores, they are making it far more difficult, and often impossible, for them to be able to commence business for themselves when the time comes, surely it should influence them to resolve not to help in any way towards such a result, not even if for a time they are offered somewhat seductive advantages.

Phenol.

Sir,—In Mr. Coul's interesting paper on "Carbolic Acid," the remarks on the method which should be adopted in determining the boiling-point of a liquid seem open to some criticism. The temperature at which a liquid boils may be modified by the nature of the vessel, by substances held in solution, and in the case of a mixture of liquids the temperature may be far above that of the vapour which is distilling. The theoretical boiling-point is the lowest temperature at which the substance exists in the state of vapour under a certain pressure. Hence the thermometer ought not to be placed in the boiling liquid, but in the vapour. The practical difficulty is to ensure that the vapour is not overheated, and even with such appliances as Lel-Henninger tubes it may well be doubted whether the difficulty is always overcome. One thing is certain, that the actual determination of the exact boiling-point is much more difficult than might at first suggest. This is manifest from the fact that there are very few compounds as to the b.p. of which different observers are agreed to within half a degree. For phenol, authorities vary from 180° to 182°. This variation is doubtless sometimes due to faulty methods of observation, more often to the extreme difficulty in obtaining any material of perfect purity; but just possibly there is some unknown quantity, like the unsuspected constituent of the air, which comes in to vitiates results.

THE CONDITION OF PHARMACY IN AMERICA.

BY GEORGE M. BERINGE, A.M., PH.G.

If the question were professed to the educated pharmacists of the United States, "Is your condition socially, professionally, and financially satisfactory?" but comparatively few could answer in the affirmative either phase of the interrogation. The examination of current American pharmaceutical literature would likewise present a negative answer. That this dissatisfaction with the present condition of pharmacy is likewise spreading on the opposite side of the Atlantic appears evident from the tone of recent pharmaceutical writings. Many are wasting time and space of the journals in deploring the changes in pharmacy, for which, perhaps, they are blamable, without presenting a single item of scientific or educational value that would tend to elevate the pharmacist from his present state. We have every evidence that the educated pharmacists of the United States are not satisfied with their present position in society, but are preparing to seek that recognition and professional standing to which, by education and training, they should be entitled.

The writer frankly admits that the thought, "Not what I am but what I hoped to be comforts me," expresses his own condition and, he believes, that of a majority of the intelligent pharmacists of America. According to public opinion, the pharmacist is not, as a rule, looked upon as possessing any peculiar education or standing that would warrant him to assume a position higher in the social scale than that of his neighbours who are confectioners or grocers. The American public has been educated to classify as professional, the minister, the lawyer, the doctor, and the politician, and the methods of the latter are very apt to be copied in matters not political. Although the studies of the pharmacist may have been as extensive, and the time still spent in his studies, if he be conscientious in the discharge of his duties, may be equal to that of either the lawyer or the physician, he is exceptionally indeed recognised as their equal. Particularly objectionable is the air of superiority assumed by the average young man who has been but recently inflated with the degree of M.D. Also, this is too frequently admired by the pharmacist. The writer recalls a recent experience with such a medical student. When questioned on the purity of a specimen of oil of gaultheria, because, "It was not as it ought to be, distilled from the roots of the shrub."

At the present time, our professors in the various colleges of pharmacy are alone accorded a standing as professional pharmacists. They are, as a rule, learned specialists, whose ability in their special departments is beyond question, but generally, not now, if ever, actively engaged in the drug business. And here, again, one has but to examine the list of teachers to discover with what reverence the degree M.D. is considered a requisite for a teacher of pharmacists.

That pharmacy in America has reached a critical period in its history is acknowledged. Various are the reasons assigned for its unsatisfactory financial and professional condition. Foremost is the "bargain-hunting" tendency of the public. While professing to be in love with the principle of protection, the American people practise daily, each in their own sphere, to the heart's desire of the most pronounced free-trader, the right of buying in the cheapest market. The pharmacist suffers from this no more nor less than other tradesmen.

PROBLEMS AFFECTING PHARMACY.

The pharmacist of to-day finds himself confronted with a number of problems in his business which were not presented to his predecessors. His business is now necessarily of a two-fold character. While part of his labour and duties to society require a training of a scientific character, the majority of his transactions are purely commercial. Commodities, such as hair-brushes, toilet powders, perfumery, and "patent medicines," require no special skill or education to sell, and the American pharmacist is here brought in direct competition with the "patent medicine" cutter, the grocer, the dealer in dry goods, and that modern renovation of the general store of last century, the large department store. If he wishes to retain his patronage he is compelled to prove himself as shrewd a merchant as these new competitors. Cutting in the price of such commodities is but the natural result of that sharp competition that at present marks all commercial enterprise. The public cares not for the professional standing of two salesmen of such commodities, and will patronise the one who sells the cheaper. The druggist cannot expect his business to be an exception to general laws, and must learn to adopt himself to those changes which are continually occurring in commercial occupations.

Someone says "That the selling of such materials is foreign to the occupation of the pharmacist." Perhaps so, and I trust that in the future this ideal of pure pharmacy may be realised. But, at the present time, what community would support druggists who took such a radical stand, and kept only medicines in the strictest sense? Here and there we do find a store in which this has been attempted to a moderate degree, but in the majority of cases such stores are pecuniarily situated, or the property of physicians whose practice sustains them.

The pharmacist engages in business from the same selfish motive, that of profit, as actuates the baker or the banker, and as a business man he must supply the legitimate wants of his patrons. A lecture is the prescription. He must, therefore, be sure to divert his trade to the more shrewd, even if less conscientious competitor. At present, comparatively few pharmacists would exist without such accessory business. In a recent issue of one of our pharmaceutical journals, the editor advises as a needed reform "That pharmacists cut out of their stock all proprietary medicines the composition of which is unknown." An examination of the advertising pages of the same journal showed them filled with advertisements of nostrums. Would it not be advisable for the editorial and the business managers of that journal to get in harmony and consistently commence this "cutting out" business at home? It is noticeable that the writers of such refrains are generally editors or physicians, and not those who actually have to deal with the problem.

It must be admitted that the present condition of pharmacy in America is largely due to the class...
of men who have overcrowded its ranks. Many are illiterate and engaged in a calling for which they have neither fitness nor innate love. It is a fact, that a large percentage of the druggists still lack a scientific education fitting them for their duties. Yet, strangely, while the leaders of pharmacy are acquainted with the shortcomings of the American pharmacist, and heartily desire his elevation, their national pride is such that they deprecate any criticism either at home or abroad. Would it not be far more honest to frankly admit that educated pharmacists are in the soda water, cigar, "patent medicine" business, etc., not from any personal desire, but because under the present condition of our society it becomes necessary for a successful business career.

MEDICAL MEN AND PHARMACY.

In his legitimate sphere—dispensing—the pharmacist finds himself encroached upon by the physician who, not content with his fee for prescribing, would deprive the pharmacist of his meagre earnings from compounding. The physicians of the United States are being encouraged in dispensing by some of the manufacturing pharmacists. With characteristic effrontery, they send one salesman to the druggist, professing to protect his interest by not selling to physicians, and another salesman directly to the doctor, diluting on the advantages of dispensing their tablet triturates, etc. With complete hypocrisy the same enterprising manufacturers influence medicine and pharmacy through the journals which they either own absolutely or control through advertising contracts.

The city of Camden, N.J., on the opposite side of the Delaware from Philadelphia, and almost under the shadow of the medical and pharmaceutical colleges of the latter city, illustrates forcibly to what extent this custom is growing. With fifty drug stores; of that number physicians own twenty-seven. Out of ninety regular physicians, fifty-five are interested in supplying their patients with medicines, either as proprietors of stores or directly from their offices. This same condition exists in many localities even in the larger cities. To such an extent has this increased in New Jersey that one of the State Board of Medical Examiners recently expressed his opinion to the writer, "That within another decade there would be no druggists, as every physician would dispense his own medicines." I beg leave to dissent from this view, as the awakening to a higher education of both the medical and the pharmaceutical student will lead to specialisation and the divergence of the two professions whose lines appear to have been converging.

It is apparent that one of the evils resulting from incompetent pharmacists is the selection of improper apprentices, and thus the preceptor may stamp his unfitness upon several generations. The schools of pharmacy have been peculiarly remiss in deciding the qualifications of students admitted to instruction. In many there is a lack of any regulations requiring the student to possess even a common school education. It has been thought advisable to leave the determination of the fitness of the applicant for "drug honour" entirely to the proprietor, but it will be necessary for several generations of proprietors to pass away before we can notice much improvement. The necessity for selecting better material for our future druggist is essential before we can expect any decided advance of the profession of pharmacy.

LACK OF SCHOLASTIC TRAINING.

Our colleges of pharmacy are awakening to the necessity for more thorough tuition, and are improving and extending their instructions. But it certainly is impossible to impart a scientific, professional education to those who lack as a foundation even a common school training. The fear of losing a few students is the strongest argument that can be advanced against the adoption of preliminary examinations by the college. Such arguments should be beneath the dignity of a school for professional instruction. While it is necessary for the pharmacist to manage his store for the purpose of money-making, this should not be the object of the colleges. The teaching of pharmacy, at least, should be kept above the level of a money-making enterprise.

But very few of the young men now entering pharmacy have been favoured with a preparatory collegiate education, and it becomes somewhat of a problem to wonder, under the present position of pharmacy, and the public opinion of the same, men of education can be induced to enter its ranks.

SUGGESTED REMEDIES.

The evils leading to the present condition of pharmacy have been recognised, and the remedies suggested have been legislation and combination. The pharmacy laws of the various States are not uniform in their requirements, and the certificates of registration are not now, as a rule, recognised outside of the State issuing them. In Pennsylvania no diploma is accepted as proof of the qualification of the applicant for registration, who is compelled to pass an examination. In New Jersey the Board of Pharmacy accepts as sufficient the diploma of any reputable American college, provided the college has required of the graduate at least four years' practical experience in the store. Many of the laws drafted as pharmacy laws have been so amended in the halls of legislation as to exempt from their provisions the doctors of medicine, or even to extend to them privileges not granted the educated pharmacist.

Various plans of combination have been suggested to prevent cutting, but all such have sooner or later failed. Whatever the improvement or the reforms that may be accomplished they will not be the result of either legislation or combination, but must emanate from pharmacy itself. We must have better material to commence with; young men whose idea of pharmaceutical education is something more than just sufficient to obtain a degree. We must have all our pharmaceutical colleges aiming to impart the most thorough education, to graduate the most perfect students. Their aim must be higher education, not larger classes, and their diplomas must be conferred only on those possessing a knowledge and skill befitting a professional standing. We must have pharmaceutical journals that sustain and advance the scientific and professional side of pharmacy, and are unwilling to sell their honour and influence for advertising patronage. Above all, the public must be educated to appreciate competent, thoroughly educated pharmacists. The present condition must be the foundation for future advance in American pharmacy.
THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD.*

BY SIR GEORGE JOHNSON, M.D., F.R.S.
Emeritus Professor of Clinical Medicine and Consulting Physician to King's College Hospital; Physician Extraordinary to Her Majesty the Queen.

The author adduces additional and, as he believes, conclusive evidence of the absence of sugar from normal urine, while pointing out that whether a trace of sugar does exist in normal urine or not is a question of interest to chemists and physiologists, but one of no practical importance. For the clinical observer the presence or absence of glycosuria may be decided in about two minutes by the following simple test. A draconch of urine—or, what is nearly the same amount, 4 C.c.—is placed in a test-tube about half an inch in diameter, and to this is added an equal volume of a saturated aqueous solution of picric acid, and half the volume—that is, half a draconch, or 2 C.c.—of liq. potassa (P.B.).† An orange-red colour instantly appears as a result of the incipient reducing action of kreatinin upon picric acid at the ordinary temperature. The colour is deepened by boiling, and if, after the liquid has been kept at the boiling point for about a minute, a bright red colour appears through the test-tube when held up to the light, the urine, for clinical purposes, may be confidently pronounced free from sugar. If an aqueous solution of glucose, in the proportion of more than two grains to the ounce, be tested in the manner described, the liquid will be rendered so dark that no light is visible through the full diameter of the tube. For clinical and life assurance purposes, no other method of testing for glycosuria equals this for the ease and rapidity with which it may be conducted, and for the absolute trustworthiness of the result. The presence of sugar having been thus ascertained, the quantitative determination may be speedily and accurately effected by means of the picro-saccharometer. The method of using the saccharometer is described in an appendix to this communication.

The author, since the publication of his paper 'On some Common Sources of Error in Testing for Sugar in the Urine,'‡ has obtained additional, and he believes conclusive, evidence that no trace of sugar is to be found in normal urine.

In that paper he referred to the work of his son, Mr. George Stillingfleet Johnson, who discovered that, by the action of mercuric chloride, kreatinin, which is a constant constituent of the urine, is precipitated in combination with mercury as a definite chemical compound, from which the kreatinin, having been separated in a crystalline form, its ultimate composition and its reducing action upon cupric oxide and picric acid were accurately determined.§

The kreatinin having thus been separated from the urine, it is found that the filtrate exerts no reducing action upon either the copper or the picric acid test; and that any sugar which might be present is not removed by the mercuric chloride process, is proved by the fact, that when a known weight of glucose has been added to the urine, it is found undiminished after the separation of the kreatinin.

That by avoiding the application of heat, and the use of destructive chemical agents, the natural kreatinin of the urine has been separated unchanged, and that this is the sole agent in normal urine which exerts a reducing action upon picric acid, is proved by the fact that when the amount of picric acid reduction by the urine has been accurately determined, the indicated amount of Stillingfleet Johnson's kreatinin in aqueous solution is found to give precisely the same degree of picric acid reduction colour as the urine when the liquids are undiluted and in different stages of dilution, until the amount of kreatinin is no more than one grain by weight in 200,000 minims of liquid.

To obtain the complete reduction of picric acid by an aqueous solution of uncombined kreatinin containing 1 grain to the fl. oz., more potash is required than in testing normal urine.

The amount of liq. potassa (P.B.) must be 1 1/2 draconches instead of 1 draconch, and the liquid should be boiled for 90 seconds instead of 60. The kreatinin of the urine appears to be associated with some substance which enables it to exert its full reducing action in presence of a smaller amount of potash than is necessary when uncombined kreatinin is dissolved in water.

For comparing the colours resulting from testing diluted urine, and an equally diluted solution of kreatinin, the simplest plan is to place a draconch of each liquid in two test-tubes of equal diameter, to add to each 1 draconch of picric acid solution, and 1 draconch of liq. potassa, then to boil for a minute, after which, the two tubes being placed side by side, the difference or the equality of colour can be observed. If, as has been asserted, glucose were present in normal urine in the proportion of not less than 0.05 per cent., about one-third of the reducing action of picric acid would be caused by glucose, the remaining two-thirds by kreatinin.

The extreme delicacy of the picric acid reaction of kreatinin in largely diluted solutions affords a simple and accurate means of detecting a mixture of a small quantity of glucose with kreatinin, whether in the urine or in an aqueous solution.

The author has ascertained that a watery solution of glucose ceases to give any colouration with picric acid and potash when the dilution is carried beyond 1 part in 10,000 of liquid.

If, therefore, the reduction-colour in normal urine were in part due to the presence of a small proportion of glucose, the colour resulting from an analysis of the urine and of an aqueous solution of kreatinin of the same reducing power, which is equal when the

* Urio acid reduces cupric oxide, but not picr acid.

† See a letter by the writer on the Value of 'Picric Acid as a Test,' in the *Lancet* of Jan. 23, 1894.
two liquids are undiluted, would be unequal when the dilution is carried beyond the point, i.e., 1 grain in 10,000 minims of liquid, at which glucose ceases to exert any reducing action upon picric acid.

The urine would be paler than the equally diluted solution of kreatinin in proportion to the amount of sugar therein contained.

It should be borne in mind that the reducing action of kreatinin upon picric acid and potash is less than that of glucose, in the proportion of 10 to 12.

When the reduction of a normal urine is 0-8, calculated as glucose, the amount of kreatinin to give the same reduction colour would be 0-96.

It must also be remembered that, while the reducing action of glucose upon picric acid and potash ceases when the dilution is carried beyond 1 in 10,000, that of kreatinin continues until the dilution reaches 1 part in 200,000.

It has invariably been found that by comparing the colour resulting from the picric acid test applied to normal urine with a solution of kreatinin of equal reducing power, when the colours in the undiluted specimens have been equal, they have remained equal after the two liquids have been diluted beyond the point at which the action of glucose must have been eliminated, had any glucose been present. Amongst other experiments the following is described. A sample of urine gave with picric acid a depth of colour indicating 0-6 gr. per fl. oz., calculated as glucose. To 1 fl. oz. was added 0-3 gr. of glucose. By this addition the amount of reduction was raised to 0-9 gr. per fl. oz., two-thirds being due to kreatinin, one-third to the added glucose.

The reducing power of kreatinin being less than that of glucose in the proportion of 10-12, the amount of kreatinin required to give the same colour as the saccharine urine was 1-08 grain in 1 fl. oz. of water. The testing of the undiluted urine and of the kreatinin solution respectively, gave a red coloration of exactly the same tint.

When the two liquids were tested after they had been diluted, so that the proportion of solid to liquid was 1 in 14,000, the action of the glucose having been eliminated, the urine was considerably paler than the kreatinin solution. If it had not been known that one-third of the reducing action of the undiluted urine was caused by the added glucose, the fact might have been ascertained by observing that in order to equalise the colour of the two liquids, when tested after dilution had been carried beyond the point at which glucose ceased to exert its reducing influence, one-third of its volume of water had to be added to the kreatinin solution.

Here, then, we have a simple method by which not only the absence of sugar from normal urine may be ascertained, but the exceptional presence of a small amount may be quantitatively determined. Such exceptional presence being, it is believed, abnormal and extremely rare.

The author states that, for experimental purposes, the pure urinary kreatinin may be obtained at Apothecaries' Hall.

APPENDIX.

Directions for the Quantitative Determination of Sugar in Urine by Sir George Johnson's Micro-Saccharometer.*

The following solutions are required:—

1. Standard solution of ferric acetate, equal in tint to that yielded by a solution of glucose containing 1 grain per fl. oz. This standard solution is prepared as follows:—

   B. Liquor ferric perchloridum fortior (P.B., sp. gr. 1·42) .................................... 3i-
   Acidi acetici glacialis (P.B., sp. gr. 1·058) ................................... 3iiv.
   Liquor ammonii (P.B., sp. gr. 0·959) 3ij.
   Aquam destillettam .................................. ad 3ij.
   Mix first the iron and the acid; then add the ammonia, and water up to 4 fl. oz.†

2. Saturated solution of picric acid, prepared by boiling the crystals with distilled water in the proportion of 6 grains to 1 fl. oz., and allowing the excess to crystallize out on cooling.

3. Liquor potassae (P.B., sp. gr. 1·058).

Apparatus Required.

1. A tube about 12 inches in length, graduated into 100 cubic centimetres, with longer divisions at each 10 cubic centimetres, accurately stopped and lipped.

2. A tube, half the above length and of equal diameter, accurately stopped to hold the standard solution.

3. A boiling tube, 10 inches long, 3 inch in diameter (internal), lipped, and graduated up to 4 fl. drachms.

4. A one drachm measure.

Method of performing the Analysis.

Measure 1 fl. drachm of urine into the boiling tube. Add 1 fl. drachm of the saturated picric acid solution, and 3 fl. drachm of liquor potassae. Make up to the 4 drachm mark on the tube with distilled or rain water. Heat over a spirit or gas lamp, and keep the liquid boiling for about a minute. Cool by dipping the tube after a minute in cold water, and ascertain that the cold liquid measures exactly 4 fl. drachms. If less, make up to the 4 drachm mark with distilled water; if more, evaporate down to the 4 drachm mark. If the colour of the boiled liquid is the same as that of the ferric acetate standard or paler, the urine is either free from sugar or contains less than 1 grain per fl. oz. If the colour is paler than the standard, boil with 2 drachms of urine instead of 1, then divide the indicated reduction by 2. In analysing an undiluted urine the phosphates precipitated by the potash often cause turbidity, which must be removed by filtration before the colour can be accurately estimated. It should be borne in mind that all normal urines reduce picric acid to an extent equivalent to from 3/4 grain to 1/2 grain of glucose per fl. oz. This reduction is due to kreatinin. This should be allowed for when the quantity of glucose present is very small. If the colour of the boiled liquid is darker than the standard,

* Made by Messrs. C. F. Müller & Co., 148, High Holborn, W.C.
† The standard ferric acetate solution may be obtained from any pharmaceutical chemist.
introduce it into the graduated tube until it stands at 10 divisions, whilst the stoppered tube at the side is filled with the ferric acetate standard. Now dilute the dark red liquid in the graduated tube with distilled or rain water till the colour is the same as that of the standard. Each division above 10 = 0.1 grain per fl. oz. Thus, 18 div. = 1.3 grains, 30 div. = 3 grains per fl. oz., etc. If more than 6 grains per fl. oz. are indicated, dilute the urine 10 times by pouring urine up to 10 divisions on the graduated tube, and distilled or rain water up to 100. Then analyse the diluted liquid as before. In this case each division on the saechometer indicates 1 grain of sugar per fl. oz. Thus, diluting from 10 up to 48 divisions shows that the urine contains 48 grains of sugar per fl. oz. If the urine, when 10 times diluted, gives a colour paler than the standard, it contains less than 10 grains of sugar per fl. oz. Another portion should then be diluted 5 times by filling the graduated tube up to 10 divisions with urine, then up to 50 divisions with distilled or rain water.† The analysis is performed as before. The value of the divisions now will be half that with a 10 times diluted sample. Thus, 18 divisions would indicate 9 grains per fl. oz. If the urine has a specific gravity of 1.052 or more it should be at once diluted 5 or 10 times before commencing an analysis.

The percentage weight of sugar to the volume of urine may be ascertained by dividing the number of grains per fl. oz. by 4.8.

**TEA SEED.**

BY DAVID HOOPE, F.C.S.

(Concluded from page 588.)

The oils of tea seeds have been submitted to very critical examination by chemists, and favourable reports have been passed upon them. Mr. R. H. Davies of the Apothecaries' Hall, London, examined in 1885 some oil from China. He stated that the specific gravity was 0.917, and it began to congeal at -13°C. It yielded 93.94 per cent. of fatty acids containing 83.15 per cent. of oleic acid. Saponification equivalent 195.5. The bitterness of the oil was marked, but it was not found to have any drying property.

Mr. L. van Itallie, of Rotterdam, arrived at almost the same conclusions from his examination of a sample of oil drawn and refined from Assam tea seed. He found the oil to have a specific gravity of 0.920, and a congealing point of -12°C. It yielded 91.5 per cent. of fatty acids containing 72 per cent. of oleic acid. Saponification equivalent 194. The oil had an acrid taste, but, in this case, it was observed to have something of the properties of linseed oil. These two analyses show that tea oil consists largely of olein, and resembles the well-known fixed oils of olives, almonds and safflower, but the presence of an acrid substance militates against its use in European cooking, in place of salad oil. Katrujma, a Japanese scientist, made an investigation in 1879 of the acrid principle of camellia seed, and found it to be as poisonous as foxglove. This statement has lately received confirmation in the fact that one of the active principles of foxglove belongs to the class of saponins, and has a similar action upon the heart.

A small bag of tea seeds was placed at my disposal by a friend on the Nilgiris, and I am glad to be able to give a complete analysis of them. The seeds were 0.007 of an inch in diameter, rounded or hemispherical, of a chocolate brown colour. A thin, brittle integument enclosed the whitish oily kernel. The brown husks were removed, and the kernels dried in a water oven, which resulted in the loss of one-third of their weight of water. The dried kernels were reduced to fine powder, and, upon analysis, were found to contain the following constituents:

<table>

The fixed oil is much less in quantity than is found in the Chinese seeds, and is about the same as that yielded by Assam tea seed, viz., 20 per cent. The oil was bitter and acrid, but did not deposit or thicken after being kept in an exposed situation for one week.

The albuminoids, calculated from the nitrogen, are disappointingly low. Oil seed cake, or "poona", from other sources yields as much as 20, 30, or even 40 per cent. of nitrogenous matter. If the oil were pressed out, the cake would still be comparatively poor in this ingredient, which is so useful in all substances employed for manurial purposes.

The saponin is the poisonous glucoside already alluded to. With such a large proportion of noxious material, it would be impossible to recommend the seed cake for feeding stock.

The carbohydrates consist of sugar and mucilage which are present in all seeds. No alkaloid, such as caffeine, was detected in any of these extracts.

The mineral matter is very low, and would be of little value for the sake of any phosphoric acid and potash it contains.

In conclusion, I would recommend that —

1. **Tea seed is not suitable for manufacturing a fixed oil.** The proportion of oil in the seed is much smaller than that found in well-known oil-bearers, as sesame, coco-nut, and castor. The oil is difficult to express on account of the emulsifying property of the saponin. The saponin is poisonous, and appears to dissolve to some extent on every occasion in the oil, which is a damaging feature, and care should be taken to obtain edible materials from wholesome sources.

2. **Tea seed should be used as a manure.** The amount of nitrogen is not so high as in many poonasses, but it is higher than the amount contained in farm-yard manure, and its application would be beneficial to the
tea if beaten into a powder and placed in the ground near the roots of the tea bushes.

3. Tea seed should be tried as an insecticide. Insects are known not to attack the seed-cakes of the “basina” and “neem” or “margosa,” because of the scald principles contained in them. For the same reason they would keep away from substances containing the poisonous saponin, and would be killed with a strong infusion of the seeds. The seed could be used in two ways, either as a decoction or as a dusting powder. In the first case, the bruised seed should be allowed to stand in boiling water, and then filtered from the fibrous material. The clear liquor may then be applied to the plants infested with the pest. Or the seeds may be reduced to fine powder and sprinkled over the plant or near the ground where the insect or blight abounds.

I have made some experiments in using tea seed cakes as a fuel in the same way as “goblins” is used in the North of India, but the large quantity of carbohydrates soluble in water prevents rapid and complete ignition of the dried cake, and smouldering for the same reason cannot take place.—South of India Observer Press.

THE RELATION BETWEEN CHEMICAL CONSTITUTION AND PHYSIOLOGICAL ACTION.  

By T. Rhysber Marshall, D.Sc., Edin., Professor of Chemistry, St. Mungo’s College, Glasgow.

There is now no doubt, from recent researches, that a close relationship exists between the constitution of a chemical substance and its physiological action. This connection was observed by Bunsen in 1843, even when a knowledge of the constitution, especially in regard to saturation, was practically unknown. Bunsen found that ascorbic acid (CH₂O)₄PO₄, which contains about 64 per cent. of arsenic, is inert, although absorbed into the system, and he thus clearly saw that the composition alone of a substance was insufficient to explain physiological action, but that constitution—that is, the structure of the molecule—must also be considered.

One of the first and most important steps to a knowledge of this relationship was made by Professors Crum-Brown and Fraser, who showed that the introduction of methyl into the molecule of strobionine or thebaine changed the tetanising action of those poisons on the spinal cord into a paralysing one on the ends of the motor nerves. This conclusion has lately been found to be incorrect, as the tetanic action is not altered by the saturation of the compound by methyl iodide, but simply masked by the motor nerves being paralysed.

In this paper I shall confine myself to the consideration of the physiological action of carbon monoxide, carbon dioxide, methane, and ammonium, and a few of the derivatives of marsh gas and ammonia, both for the sake of simplicity and for the purpose of showing that the physiological action of a substance of known constitution may even, now, in some cases, be predicted with certainty.

SATURATION.

The pharmacological activity of a substance depends largely on the degree of saturation, and the study of the compounds of carbon and oxygen bears this out in a marked degree. The atom of carbon has four separate points of attraction for other substances for which it has an affinity when brought under the necessary conditions. If excess of carbon be heated with oxygen only two of these affinities will be satisfied, and the active substance carbon monoxide is produced, and as it still contains two free affinities, the compound is termed unsaturated. The physiological activity of carbon monoxide is due to this state of unsaturation, and is thus capable of combining with the hemoglobin of the blood, thereby impairing its function as an oxygen carrier. If we burn carbon monoxide, then the higher oxidation product, carbon dioxide, is formed, and now the substance is saturated—that is, the carbon no longer possesses free affinities. It is thus easy to understand, from the consideration of the degree of saturation, that carbon dioxide cannot be an active poison like carbon monoxide, as it is no longer capable of forming firm compounds with active organio substances.

However, it cannot be considered altogether inactive because, in the presence of water, it forms carbonic acid, CO₂OH, a weak member of a class of bodies possessing a distinct action on living protoplasm.

MARSH GAS AND MARSH GAS SERIES OF HYDROCARBONS.

Marsh gas, CH₄, which is a compound where all the free affinities of carbon have been satisfied by hydrogen, is a perfect example of an inert saturated compound in the physiological sense. When inhaled, largely diluted with air, it causes no disturbance in the animal system, but produces an anaesthetic action when breathed in quantity, not because it acts directly on living tissue, but for the reason that it prevents oxidation by exclusion of oxygen.

Marsh gas is the first of the series of very stable hydrocarbons known as paraffins, which may all be derived from marsh gas by continuously replacing a hydrogen atom by the methyl radical CH₃. The volatile members of this group act as anaesthetics by a process of suffocation, and the higher members are quite inactive, not possessing any recognisable physiological action.

UNSATURATED HYDROCARBONS.

If, however, hydrogen be removed from the paraffins, their active unsaturated compounds are formed. Ethylene, C₂H₄, the first member of the olefine series of hydrocarbons, like marsh gas, acts as an anaesthetic, but owing to the free affinities is much more dangerous to life by acting similarly to carbon monoxide. Acetylene, C₂H₂, a still more unsaturated substance, is more poisonous than ethylene.

THE HALOGEN DERIVATIVES OF THE PARAFFINE.

The paraffins, although inert saturated compounds, may be rendered very active by directly substituting hydrogen atoms by halogen atoms. In all these derivatives the halogens are more firmly bound than in their salts, but, notwithstanding, the halogens still exert a distinct general physiological action of their own, so that in a compound like chloroform, CHCl₃ (which is marsh gas with 3 hydrogen atoms replaced by chlorine atoms), not only must we consider the
effect of a saturated hydrocarbon, but also the action of the chlorine present.

Chloroform, therefore, acts as an anesthetic (1) by a process of suffocation; (2) by causing, in virtue of the chlorine present, semi-coagulation of the protoplasm in the nerve cells.

It has been found by experiment that the pure halogens cause anesthesia by producing partial coagulation in the nerve cells, and they also act still more strongly on muscular fibre. This action on protoplasm is also produced in a modified degree by the halogen derivatives of the paraflins, and in considering the choice of an anesthetic, it is important to remember the physiological action of the halogens. Although chloroform is one of the most convenient anesthetics, still, owing to the presence of so large a percentage of chlorine, the tendency to paralyse muscular tissue is great. There is little doubt that a safer compound could be selected, having all the convenient properties of chloroform, by choosing one of the chlorinated higher paraflins. Great care must be exercised that these halogen derivatives be used pure, as very frequently grave disturbances and even fatal results have been produced by impurities.

The bromine and iodine derivatives exert a more powerful influence than the chlorine compounds, but they are partially decomposed in the presence of light, hydriodic and hydrobromic acids being split off.

The Oxigen Derivatives of the Paraflins.

The paraflins are capable of being oxidised indirectly into three totally distinct classes of bodies, each having a special general physiological action of its own. If we successively introduce into methane or ethane three oxygen atoms, we obtain types of these classes—

\[ \text{CH}_4 \quad \text{CH}_3 \text{CH}_2 \quad \text{CH}_2 \text{CH}_2 \text{H} \]

\[ \text{CH}_2 \text{OH} \quad \text{CH}_2 \text{CH}_2 \text{OH} \quad \text{CH}_2 \text{CH}_2 \text{OH} \text{H} \]

\[ \text{CH}_3 \text{OH}_2 \text{H} \quad \text{CH}_3 \text{CH}_2 \text{OH}_2 \text{H} \quad \text{CH}_3 \text{CH}_2 \text{OH}_2 \text{H} \text{H} \]

These substances may be considered as hydrocarbons where hydrogen atoms have been replaced by the residue, hydroxy. This residue is one of the most important in chemistry, and its presence in organic substances influences the physiological action to an enormous extent.

Alcohols.

The class of bodies where only one hydroxyl group is attached to a carbon atom is known as the alcohols. We shall now only consider the case of the simple alcohols of which methyl alcohol is the type, and where only one hydrogen in the paraflin is replaced by hydroxyl.

The activity of the alcohols is due to the hydroxyl residue, which probably produces physiological effects by entering into loose combination with nervous tissue, thus interfering with the processes of oxidation and reduction, on which its activity depends. Alcohols, by abolishing to a greater or less extent the excitability of all the nerve centres, acts as hypnotics and anesthetics. The higher alcohols produce prolonged sopor, owing to the greater density and the influence of the larger number of carbon atoms on the hydroxyl residue.

(To be continued.)

NOTES ON RECENT SCIENTIFIC INVESTIGATION.

Displacement of Carbon in Molten Cast Iron by Boron and Silicon.—The study of the solubility of carbon in different metals, or in the same metal at varying high temperatures, has led H. Molissan to investigate the action of boron and silicon upon a definite carbide of iron maintained in the liquid state. The metal experimented upon contained 3:18 p.c. of total carbon and 0:5 p.c. of slag. Ten grammes of this and 2:5 Gm. of boron were placed in a boat, which was enclosed in a tube filled with dry hydrogen, and heated in a reverberatory furnace. After the experiment the metal was yellowish in colour, with some long prismatic crystals on the surface, and, on analysis, was found to contain 8 to 10 p.c. of boron, but only 0:27 p.c. of carbon, whilst the matters constituting the slag had been entirely eliminated. The tube was covered with a black felt-like layer of graphite. A further sample of metal containing 3:24 p.c. of carbon, and 0:418 p.c. of slag was experimented with under similar conditions four times, and the percentages of each left after the action of the boron were as follows:—

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon</td>
<td>0:36</td>
<td>0:28</td>
<td>0:17</td>
<td>0:14</td>
</tr>
<tr>
<td>Slag</td>
<td>0:02</td>
<td>0:00</td>
<td>0:03</td>
<td>0:01</td>
</tr>
</tbody>
</table>

In another specimen of iron the percentages of carbon and slag were reduced from 3:35 and 0:36 respectively, to 0:24 and 0:06. On adding to molten carburetted iron 10 p.c. of iron containing 10 p.c. of boron, the percentage of carbon present was reduced from 3:75 to 2:83, and a very hard white button resulted which was not affected by a graver. In the case of silicon the results were similar, and the two elements—boron and silicon—thus appear to act by precipitating the carbon from its solution in the molten metal, just as certain compounds precipitate others from their aqueous solutions (Comp. rend., cxix., 1172).

Iron Chromates.—Thirteen iron chromates have been prepared by O. Lepeirre, of which two only were already known. They are all coloured double salts, and are generally hydrated. Those derived from ferrous salts are less rich in chromium than those from ferric salts, and of the latter the richest are those prepared from the bichromates. The percentage of iron oxide is greatest in the ferrous chromates, and varies from 23 to 26 in the ferric chromates. These iron chromates form a series parallel with that of the corresponding basic sulphates, and are adapted for painting upon earthenware or china (Comp. rend., cxix., 1215).

Nickel and Cobalt Sulphides.—The compounds of sulphur with nickel and cobalt are but little acted upon by hydrochloric acid, even when it is sufficiently concentrated to dissolve readily antimony, tin, or cadmium sulphides, etc., which are completely precipitated by sulphuretted hydrogen, in dilute acid solutions of the salts of those metals. On the other hand, solutions of neutral nickel and cobalt salts containing mineral acids are not precipitated immediately by sulphuretted hydrogen, and not at all in the cold, in the presence of a slight excess of acid-
This contradiction may be explained, according to A. Villiers (Comp. rend., cxix., 1208), by the supposition that nickel and cobalt sulphides, at the moment of formation by the action of alkaline sulphides, are in a different molecular state to that in which we know them, and they may then be attacked by acids, though they are almost immediately transformed into their normal condition. It is suggested that if the sulphides were precipitated at a very low temperature, the assumed change of state might be retarded, and the existence of their unstable modifications be proved.

In a subsequent paper (Comp. rend., cxix., 1263) it is shown that the two sulphides, at the moment of their formation, are either incapable of dissolving in alkaline sulphide, or that they change so rapidly into their more definite modifications that they are unaffected by it. The latter conclusion appears to be confirmed by the fact that when very dilute solutions are employed (3 or 4 Cgms. of salt per litre), to which a great excess of soda is added, nickel and cobalt sulphides are completely dissolved by the alkaline sulphide, forming coloured liquids, which are stable even on evaporation.

Calcium Ethylate.—A specimen of the compound formed by heating calcium carbide, CaC₂, with absolute ethyl alcohol at 180° has been examined by M. de Forcrand, who concludes that it is not calcium ethylate, Ca(C₂H₅)₂, but an addition compound of alcohol and calcium oxide, 3CaO + 4C₂H₅OH, formed according to the following equation: CaC₂ + 2C₂H₅OH → CaO.C₂H₅OH + C₂H₆. The compound CaO.C₂H₅OH may combine with a greater or less excess of alcohol to form several definite compounds (Comp. rend., cxix., 1266).

Action of Mould-Fungi on Albumin.—M. E. Marchal has tested the changes produced in a 10 per cent. solution of white of egg by the growth of different kinds of mould-fungi. A number of species belonging to the genera Penicillium, Mucor, Botrytis, Aspergillus, Isaria, etc., possess the power of decomposing the albumin, appropriating the carbon and nitrogen; while other species of the same genus displayed this property but feebly, and others produced only yeast forms. In all cases where decomposition takes place, even when only yeast forms are produced, the albumin is transformed into ammonia. In no case could any production of nitric acid be detected. The species which produced the most rapid decomposition were Aspergillus terricola and Cephalothecium roseum (Bull. Soc. Bot. France, 1894, p. 408).

Heliotropism in Plants.—Dr. W. Rothert has recorded the results of a large number of observations on the heliotropic curvature of seedlings. If a portion of an organ is illuminated on one side only, the heliotropic irritation may be transmitted to other portions of the organ which are illuminated either on both sides or on neither. This transmission was observed in all the organs examined, and invariably in the basipetal direction. It takes place through the fundamental parenchyma, the vascular bundles taking no essential part in it. As a rule, the entire region over which the curvature extends is heliotropic; but the degree of sensitivity varies greatly in different parts of the organ. It is only a very short apical region in which heliotropic sensitivity is very strongly marked. The author distinguishes between heliotropic sensitiveness and irritability, these two phenomena being dependent on different properties of the protoplasm. Irritation may be direct or indirect, that is, may be the result of a local sensitiveness, or may be transmitted. The power of heliotropic curvature is dependent on four factors, the anatomical structure, the thickness, the intensity of growth, and the heliotropic irritability of the organ. It is not necessarily dependent on the sensitiveness of the part; the curvature may be the result of an irritation transmitted from another part. For the same reason, the maximum power of curvature does not necessarily coincide with the maximum intensity of growth. The power of heliotropic curvature ceases with the cessation of growth, while heliotropic sensitiveness and irritability are entirely independent of growth, and continue after the power of growth and of curvature have completely ceased. The decapitation of a seedling has two results, a diminution in the rate of growth, and an entire destruction of its heliotropic and geotropic sensitiveness; but both effects are only temporary (Cohn’s Beiträge zur Biologie der Pflanzen, 1894, Heft. 1).

Influence of Different Rays of Light on Plants.—Herr E. Wollny finds that yellow light has the greatest power of producing organic substances in plants; next the red; while blue light has a remarkably prejudicial effect on the development of the reproductive organs. It is, therefore, the most refrangible (chemical) rays which take the least part in metabolism, the assimilation of carbon being carried on mainly by the less refrangible (illuminating) rays (Wollny’s ‘Forschungen,’ 1894, p. 217). As the result of another series of experiments, M. Villon states that the vine produces a greater weight of grapes, which also contain a larger quantity of alcohol and of acid, when grown behind glass coloured red-violet by manganese, which absorbs the yellow and brown rays. Flowers are also favourably influenced by the same colour, which is, moreover, advantageous to the growth of bacteria, yeast, and silkworms (Revue scientifique, 1894, p. 406).

Grafting of Herbaceous Plants.—As the result of a series of experiments, chiefly on Cruciferae and Leguminosae, M. L. Daniel states that graft-hybrids may be produced in herbaceous plants; and that these can be endowed with new alimentary powers by grafting them on varieties which excel them in this respect, and sowing the seeds produced on the graft. Different plants differ greatly in their power of acquiring new characters. It appears to be especially strongly marked in the Cruciferae. With etiolated herbaceous plants all attempts at grafting were unsuccessful (Bonnier’s Rev. Gén. de Botanique, 1894, p. 566). Professor H. Vöchtling, on the other hand, while he succeeded in grafting Helianthus tuberosus on H. annuus, states that no graft-hybridisation takes place. Each species preserved fully its own characters; there was no tendency to the formation of tubers on H. annuus; nor did this latter produce flax (Sitiz über. K. Preuss Akad. Wiss. Berlin, 1894, p. 708).
The Pharmaceutical Journal
FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, JANUARY 19, 1895.

Editorial Department.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to "Street Brothers," 5, Sorie Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased. Cheques and money orders must be made payable to "Street Brothers."

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Bruny ride — 17, Bloomsbury Square, London, W.C.

CALENDAR FOR 1896.

The Society's Calendar for 1896, the publication of which is announced in the advertisement columns of this issue, appears at a somewhat earlier date than its predecessor, but this circumstance does not seem to have prejudicially affected the practical value of the work. On the contrary, we are inclined to think that, in many ways, the present edition is distinctly better than the previous ones. We notice that a radical change has been made in the arrangement of the matter. The lists of Members, Associates, and Students of the Society have been removed to the end of the Calendar; not from any disregard of their importance, but simply to facilitate earlier publication. They are now placed with the lists of officers of the Society, Honorary and Corresponding Members, Local and Divisional Secretaries, etc., and are no longer separated from the subscribers to the Benevolent Fund, as heretofore, by many pages of other matter. The local list of subscribers to the Benevolent Fund has disappeared altogether, but its omission can hardly inconvenience anyone, for it was only a rearrangement of the alphabetical list of subscribers; and, moreover, an exactly similar list is always published in the special Benevolent Fund issue of this Journal, which is annually sent to every person on the Register of Chemists and Druggists. A saving of space has thus been effected which will give opportunity for future introduction of additional information on subjects with which pharmacists ought to be conversant.

The Calendar has gained considerably in clearness, and consequently in general utility, by the alterations which have been made in what was formerly the Appendix. Whatever advantage there may be in printing a series of Inland Revenue General Orders and leaving them to tell their own story, is largely discounted by the confusion to which such a course inevitably leads after a few years. Like other official documents, General Orders are not always remarkable for lucidity, but when Orders which have been superseded are printed with others that are still in force, one is apt to find it rather puzzling to extract the knowledge desired. In this respect the Society's Calendar has long needed revision, and we are glad to notice that in the present edition a very successful attempt has been made to systematise the particulars relating to methylated spirit, and to embody the current General Orders on the subject in a comprehensive form. The article on "The Law relating to Methylated Spirit" is an efficient substitute for the scattered, and often contradictory, regulations hitherto appearing in the Appendix, and those consulting it will be able to obtain a great deal of information with a minimum amount of trouble. The same epitomising treatment, though in a lesser degree, has, with good results, been accorded to the regulations dealing with "Drawback on exported Tinctures," "Essences," and "Perfumed Spirits."

Recent information will also be found concerning medicated wines, juries, metric standards, &c., and a very useful innovation is the introduction of a table of licence duties, with the dates on which each licence expires. When it is considered, too, that the various Acts of Parliament affecting the pharmaceutical calling are likewise included in the Calendar, its claims as a book of reference for chemists and druggists in business will need little emphasis. Those who are not yet in business will, however, do well to peruse its pages. The Regulations of the Boards of Examiners, though, perhaps, not particularly interesting reading to students, are an important supplement to the Questions set during 1894 for the First and Major examinations; whilst the fact that the papers set in the last Scholarship competitions are also contained in the Calendar, together with the School of Pharmacy prospectus, and the questions for the various prizes offered by the Council, should make the book quite worth its published price to youths about to enter on a pharmaceutical career. Considerable care appears to have been taken to keep the Calendar abreast of recent events, and we may instance, by way of illustration, the alteration in the Benevolent Fund Regulation X., adopted at the last Council Meeting; the insertion of Mr. W. Warren's name in the list of Councillors for 1896, and the omission of the name of Professor Flockinger from the list of Honorary Members. Altogether, we think the Secretary may be congratulated on the enhanced worth of this year's Calendar.
THE ANTITOXIN TREATMENT OF DIPHTHERIA.

A particularly interesting addition has been made to the existing statistics of the results of the new method of treating diphtheria. Drs. WASHBOURNE, GOODALL and CHARD, in the British Medical Journal of Dec. 22, 1894, record the results of eighty cases in which antitoxic serum prepared at the Institute of Preventive Medicine was employed. Eight of these cases were excluded from statistics because there was some doubt of the diagnosis. Seventy-two cases were clinically typical diphtheria. All the cases were examined bacteriologically, and out of the eighty cases, only sixty gave cultures of the KLEBS-LOFFLER bacillus when examined after twenty hours' incubation on blood-serum. In thirteen cases the tubes even after three days gave pure cultures of the bacillus, the majority of these cases were of severe type, and four of them ended fatally.

It is well known that the form assumed by the diphtheria bacilli is subject to modifications, what may be regarded as the typical form in stained preparations reminds the observer of the tubercle bacillus, i.e., there is an alternation of darker and lighter points in the slender rod. But the typical diphtheria bacillus is of the same length as, but somewhat broader than, that of tubercle. In three of the cases under consideration the short variety of the bacillus was found—these three were mild cases. In ten cases the medium variety was present, half of them being mild. The ordinary long form of the bacillus was present in the remaining cases, most of which were above the average in point of severity. Thus the authors observe that the short modifications of the bacillus seem to entail a less severe course of the disease than the ordinary form. The authors record also the nature of the concomitant organisms. The BACILLUS COCCEUS occurred in three cases, staphylococcus aureus in two, and streptococcus in forty-five, but in only eighteen of these were the streptococci numerous; of these eighteen cases ten were mild.

The result of the treatment of the seventy-two cases, which had all the clinical features of diphtheria, showed a mortality of 19.4 per cent. against a mortality of 38.8 per cent. in the same number of cases admitted previous to the arrival of the antitoxin, and a mortality of 41.8 per cent. in another series of 397 cases, and 38 per cent in another group of 400 cases of clinical diphtheria treated previously at the same institutions without antitoxin. Of the sixty-one cases in which the diphtheria bacillus was found, thirteen died; a mortality of 21.3 per cent. Of the series of sixty-one cases, nine required tracheotomy, and of these nine but three died, whilst in thirteen previous series of nine tracheotomies for diphtheria there was an average mortality of 7.25. With regard to the alleged drawbacks of the method, namely, inflammation at the seat of inoculation and symptoms of intoxication, the former were altogether absent, and the latter consisted of a slight rash, which occurred in one case out of four, and in six cases there was pain in some of the joints, which lasted for three days. These phenomena were in proportion to the amount of serum used, and the stronger the antitoxic powers of the serum, i.e., the smaller the required dose, the less marked were the toxic phenomena. It was admitted by all who took part in the discussion on these results at the Clinical Society that there could be no doubt that the remedy had greatly diminished the mortality.

WHAT IS ADULTERATION?

Some years ago, when the subject of adulteration was being discussed in the House of Commons, the late JOHN BRIGGS said he regarded adulteration as a form of competition, but it did not appear whether this somewhat ambiguous remark was intended as an excuse for adulteration or a censure of extreme competition. A similar view of the matter appears to have been taken by Mr. PLOWDER in deciding the case brought before him at the Marylebone Police Court in regard to the material known as "flannelette." The prosecution instituted under the Merchandise Marks Act was based upon the assumption that the name given to the article is suggestive of a similarity to flannel. But since the flannelette consisted entirely of cotton, it was inferred that the use of this name was deceptive. The Magistrate's decision is that the application of the term "flannelette" to an article containing no wool is not a false trade description in the sense required by the Act, and that there is no legal ground for complaint unless it can be shown that the public was deceived. He held that if flannelette answered all the purposes of wool by reason of its warmth, lightness, and softness, and had been accepted, at a lower price than flannel, as good value for many years, the public could not have been grossly deceived. The fact that the prosecution had been instituted by Lancashire flannel manufacturers, who have found their business affected by the sale of "flannelette," was referred to by the magistrate, and no doubt it had some influence upon his decision. But after making due allowance for that circumstance, it is probable that the decision of the case will be regarded as possibly having an undesirable tendency. The authorities charged with the administration of the Food and Drugs Act may be reasonably apprehensive of encountering obstructions of a similar nature, if substitution or admixture is to be made free from the penalties of that Act by the use of a diminutive termination added to the names by which articles of food, drink, and drugs are generally known. This view of the matter does not,
however, appear to have been considered so much as may eventually be necessary, but as it is probable there will be an appeal from the magistrate's decision, further comment may be deferred.

REVOCATION OF PATENTS.

In the digest of patent cases published in the official journal of the Patent Office, an account is given of the cases recently instituted by the Pharmaceutical Society, and mention is made of Mr. Justice North having “incidentally stated” in Virey's case that in his opinion “the fact of a patent being taken out to evade the provisions of the Pharmacy Act, 1868, was not a ground for revocation.” According to the verbatim report of that case (see ante, p. 128), Mr. Justice North's remark scarcely went so far, and, in any case, it involved the assumption that a patent for medicine containing a scheduled poison would be a legitimate ground of exemption from the Pharmacy Act. That, however, is the real question which has yet to be decided. The summary of these cases represents, as the present position of the matter, that “the only grounds for revocation of a patent are those specified in the Patents Act, 1883, section 28, and the fact that a patent is taken out to evade the provisions of the Pharmacy Act, 1868, is not a ground for revocation.” Without pretending to question that view, it may, however, be pointed out that procedure for revocation may be altogether superfluous, inasmuch as the formal grant of a patent is always conditional, and it declares that if at any time during the term for which the patent is granted it be made to appear that the “grant is contrary to law, or prejudicial or inconvenient” to the public, the “letters patent shall forthwith determine and be void to all intents and purposes.” To sell medicine containing poison within the meaning of the Pharmacy Act, otherwise than as that Act specifies, is contrary to law. Consequently, it would appear that a patent granted since the passing of that Act for medicine containing such a poison must be naturally void, ab initio, and that the exemption of such patent medicines in section 16 can only have a retrospective application. The invalidity—on that ground—of patents for medicine containing poison, appears, therefore, to be the point to which legal action should be directed, and that would seem to be a simple mode of doing away with the obvious inconsistency which would otherwise exist between the provisions of the Pharmacy Act in regard to patent medicines and the restriction of the sale of poisons, which is the main object of the Act.

Another statement in the digest now referred to, relates to the Piper case, which is represented as having “decided that medicines entitled to be called patent medicines were not within the provisions of the Act.” The judgment in the Piper case did not really touch the question as to patent medicines, which has been raised by attempts to evade the Pharmacy Act by taking out patents, and it merely decided that proprietary medicines which are not the subject of letters patent, are not patent medicines within the meaning of the Pharmacy Act. That point of the judgment is more correctly recorded in G. Q. B., 1893, page 636, by the statement that it was held that the exemption in section 16 of the Pharmacy Act extends only to medicines which are the subject of letters patent, and not to proprietary medicines.

THE SALE OF POISONS.

In answer to a correspondent—who holds the qualification of assistant by examination of the Society of Apothecaries, and is engaged as an assistant to a licentiates of that body—the British Medical Journal expresses the opinion that he would be protected in selling paregoric and other scheduled poisons, “provided that, if the employer keeps an open shop, the regulations of the (Pharmacy) Act as to sale of poisons are complied with.” It may be pointed out, however, that the exemption referred to applies only to legally qualified apothecaries or other legally qualified medical practitioners. The assistant qualification possesses no value whatever under the Act, and the person holding it would be liable in the event of his selling any scheduled poison, except under the personal supervision of his qualified employer.

STANDARDS OF PURITY IN AMERICA.

The State Food Commissioners in Ohio, U.S.A., are taking special steps to enforce the law dealing with the adulteration of medicines and foods. According to the Bulletin of Pharmacy, any drug may be considered impure and adulterated in Ohio, first—if, when sold under or by a name recognised in the United States Pharmacopoeia, it differs from the standard of strength, quality, or purity laid down therein; secondly—if, when sold under or by a name not recognised in the United States Pharmacopoeia, but which is found in some other pharmacopoeia or other standard work on materia medica, it differs materially from the standard of strength, quality, or purity laid down in such works; third—if its strength, quality, or purity fall below the professed standard under which it is sold.

THE PHARMACIST'S DUTY.

The Pharmaceutical Era remarks that, for his own protection and for the maintenance of his professional dignity, the druggist must test his purchases, sell them for what they are, and refuse to handle all secret preparations whose manufacturers will not secure him against prosecution or adulteration and misrepresentation. It is also pointed out that druggists who are honest with themselves, and wish to do what is right (in a moral as well as in a business way), can do much to hasten the day when tampering with food and drugs will become increasingly difficult and dangerous, by beginning at home and examining their own stocks.

CALENDAR OF THE PHARMACEUTICAL SOCIETY.

Persons desiring copies of the Calendar should apply to Mr. Richard Bremridge, 17, Bloomsbury Square, W.C. The price of the book is 2s., and we note that subscribers to the Society are not required to pay the postage on copies purchased by them.
Transactions of the Pharmaceutical Society of Great Britain.

DONATIONS.
At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 16th inst., the Librarian and Curator presented the following report of donations to the Society's Library, Museum, and Herbarium:—
To the Library in London.
Botanical Society of Edinburgh:
Transactions and Proceedings, vol. 19, pp. 235—
end; vol. 20, part 1.
George Watt, Esq., M.B., C.M., C.I.E., Calcutta (Corresponding Member):
Agricultural Ledger, 1893, nos. 1-4; 1894, nos. 1-14, 16-20; 1894, nos. 1, 2, 4, 6. 2 copies.
Royal Medical and Chirurgical Society of London:
Medico-chirurgical Transactions, vol. 77.
J. H. Maiden, Esq., Sydney (Corresponding Member):
Agricultural Gazette of N.S. Wales, Jan. 1st, 1894.
Kolenium Museum, Harleian:
Notitie vindingen door Dr. M. Ghesoff, Afevering 1, 1894.
Direktur von 's Lands Plantentuin, Butenzorg:
Mededelingen uit 's Lands Plantentuin, no. 18.
Allgemeiner österreichischer Apotheker-Verein:
Zeitschrift für 1894.
Alumni Association of the Philadelphia College of Pharmacy:
Report, vol. 30, nos. 4, 6-7; vol. 31, nos. 1-3.
The Proprietors of the American Druggist:
Numbers for 1894.
Philadelphia College of Pharmacy:
American Journal of Pharmacy for 1894.
Annual Announcement, 1894.
Society of Public Analysts:
Analyst for 1894.
The Publishers of the Archiv für Pharmacie og technisk Chemi:
Numbers from October, 1893, to July, 1894.
Pharmaceutical Society of Australasia:
Australasian Journal of Pharmacy for 1894.
Annual Report for 1894.
British Medical Association:
British Medical Journal for 1894.
The Editor of the Canadian Pharmaceutical Journal:
Numbers for 1894.
The Editor of the Chemical News:
Numbers for 1894.
Chemical Society of London:
Journal for 1894.
Proceedings for 1894.
List of officers and fellows, 1894.
The Proprietors of the Chemist and Druggist:
Numbers for 1894.
Chemists' and Druggists' Diary, 1895.
Mr. H. Helbing:
Helbing's Pharmacological Record, 1894, nos. 25-26, 28-31.
Institute of Brewing:
Transactions for January to June, 1894.
Kaiserliche Akademie der Wissenschaften in Wien:
Anzeiger, mathematisch - naturwissenschaftliche Classe, 1894.
Linnaean Society of London:
Journal, Botany, for 1894.
Proceedings, 1888-90, 1892-93.
List, 1894.
Manchester Literary and Philosophical Society:
The Publishers of the My pharmaceutisk Tidende:
Nos. 21-23, 1893; nos. 1-15, 1894.

Pharmaceutical Society of New South Wales:
Pharmaceutical Journal of Australasia, 1894.
Pharmacie Centrale de France:
L'Union pharmaceutique et le Bulletin commercial for 1894.
Royal Photographic Society of Great Britain:
Journal and Transactions for 1894.
Royal Botanic Society of London:
Quarterly Record for 1894.
The Director of the Royal Gardens, Kew:
Bulletin of Miscellaneous Information for 1894.
Royal Society of London:
Proceedings for 1894.
Société française de botanique:
Revue de botanique, July 1893 to April 1894.
Society for the Advancement of Medical Science in Japan:
Sel. I. Kwai, Medical Journal for 1894.
Society of Chemical Industry:
Journal for 1894.
The Editor of the Times:
Part 1 for 1893; part 1 for 1894.
The Proprietors of the Western Druggist:
Numbers for 1894.
To the Museum in London.
Specimen of the resin of Callitris parlatorei.
Specimens of the leaves and fruits of Pilocarpus jaborandi and of the leaves of P. trachybaphus.
To the Herbarium.
Specimens of Anemone fannini, Artemisia astra, B erythroniolum pictum, Gradiera scabra, Piper capensis, Pytholaca abysinica, Ranunculus pinnatus, Sironanthus capensis, Synnolestemon densiflorus, Tarchonanthus camphoratus.
Mr. Thea. Hamby, J. S. L., La Morte, Italy.
Specimen of Pilocarpus pennatifolius in fruit.
The Rev. J. S. Roberts, Jamaica:
Suckers of Echinoia remora used in asthma, etc., in Jamaica.
To the Library in Edinburgh.
Alumni Association of the Philadelphia College of Pharmacy:
Alumni report, 1893-94.
Pharmaceutical Society of Australia:
Australasian Journal of Pharmacy for 1894.
Pharmaceutical Society of New South Wales:
Pharmaceutical Journal of Australasia, 1894.
Mr. D. McGlashan, Edinburgh:
Pharmaceutical Journal, 1894.

EXAMINATIONS IN LONDON.
January, 1895.
(Concluded from p. 596.)

MINOR EXAMINATION—PASS LIST.
Candidates examined failed passed
Green, James 
Marshall, Geo. G. 
Nall, Walter 
Neave, R. G. 
Owen, J. E. 
Paddock, P. 
Pressey, H. H. 
Reckless, W. 
Reeves, R. 
Roberts, J. 
Skitt, J. H. 
Smith, R. E. 
Snow, W. J. 
Spencer, W. Stevenson, G. M. 
Stone, E. S. 
Stone, G. P. R. 
Tate, Anthony. 
Taylor, T. 
Whaley, C. H. 
Wilkinson, G. H. 
Williams, R. 
Wood, J. W. 
Wray, G. W. 
Younger, T. B. 
Youngusband, W. H.
FIRST EXAMINATION.

Certificates by approved examining bodies were received from the undermentioned in lieu of the Society's examination:

- Bastow, Sidney  London
- Coleman, Joseph  Bishop Stortford
- Collins, Richard Arthur  Nelson
- Dobie, James Turner  London
- Edwards, William Richard  London
- Ellul, Lawrence  London
- Forster, Horace Reginald W. Chatham
- Gray, Francis George  Birmingham
- Heywood, Robert Tracey  Wrexham
- Hoddinott, Evan James  Lochlade
- Hudson, Sidney Charles  London
- Hughes, Edward Davies  Bodelwyddan
- Knowles, John Thomas  Lancaster
- Lawson, John  London
- Platt, George  Ashton-under-Lyne
- Reynolds, Edward  Stock-on-the-Wold
- Robinson, Ernest Temple  Harrogate
- Saunders, Alfred Woods  Maldon
- Sawbridge, Frederick Bertie  Coventry
- Shea, William A. Lambert  Brighton
- Shimwell, James Hugh  Burton
- Thomas, William Henry  Blandford
- Walmley, Martin  Kingston-on-Thames

Proceedings of Societies in London.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting was held on Thursday, January 10, Mr. H. T. Durant, vice-president, in the chair.

A paper was read on

VINEGAR.

BY W. H. MAUNDEL.

After alluding to the origin of the name, and the fact that the use of vinegar was probably as ancient as that of wine, the author proceeded to describe malt vinegar and its preparation, comparing it with the brewing of beer and pointing out the differences in the two processes and their reasons. The chemical reactions involved were explained, and the constituents of the finished product enumerated. The differences between malt and wine vinegars, and the principal methods of manufacturing the latter were also described.

A discussion followed, in which the Chairman, Secretary, Messrs. Davis, Bastow, and Tunbridge took part.

A paper followed on—

ELECTRICITY IN RELATION TO CHEMISTRY.

BY F. P. A. TUNBRIDGE.

The gradual development of the science of electricity, especially in its chemical aspects, was traced, starting with the electrolysis of water by Dallmann and Piets van Troostvijk, in 1789, by means of frictional electricity, and the well-known experiments of Galvani and Volta, from 1790 onwards. The decomposition of water with the voltaic pile by Nicholson and Carlisle in 1800, the discovery of potassium by Sir Humphrey Davy in 1807, and the influence exerted by these and similar experiments on the chemical theories of the period were alluded to. Berzelius's binary theory was also discussed somewhat fully. The researches of Faraday, and, later, of Hittorf, into the laws governing electrolysis, were described, and the distinction between the primary and secondary effects of electrolysis illustrated. The light thrown by this means on the disputed composition of "double salts," such as platinno-chloride of sodium, was mentioned, and the electro-chemical theory of solution propounded by Arrhenius discussed. The ordinary primary batteries, as well as gas batteries and secondary batteries or accumulators, were briefly described and illustrated by examples; the applications of the current to various metallurgical and industrial purposes, such as the production of aluminium, copper, gold, and other metals, caustic soda and chlorine, ozone, the treatment of sewage, the maturing of wines, electrolyzing, etc., were all touched upon, and various applications, both qualitative and quantitative, in analytical chemistry.

A short discussion followed, and the meeting then adjourned.

ROYAL INSTITUTION.

On Tuesday afternoon Professor Charles Stewart delivered the first of a course of twelve lectures on the internal framework of plants and animals.

Protoplasm, which the professor said had been aptly termed the physical basis of all life, was first described, and the principal theories that are held regarding its internal structure, the distribution of spongioplasm and hyaloplasma, and the life and growth of the protoplasm were discussed. Pointing out that the latter, which has the consistency of weak gum, would, if unsupported, sink to the ground as a jelly-like mass, the lecturer showed the necessity for some supporting framework in order that living bodies might assume the various positions in which they may readily obtain the necessary food. Usually the protoplasm provides itself with an elastic membrane, the cell wall, and in some cases this provides sufficient support. The structure of a seaweed was illustrated by a description of a Delesseria and a Fucus. Professor Stewart then showed that the cell wall may be strengthened by becoming thicker and harder, and by having the substance known as lignin, or, as he preferred to term it, "lignone," deposited in it. The club-moss was selected as a suitable object on which to demonstrate the typical structure of some of the lower classes of plants. The distribution of the phloem, which is soft, and the xylem, or hard woody tissue, was explained, and it was shewn that those tissues are surrounded by a sheath of sclerechyomatous fibres acting as a mechanical support. A tree fern formed the subject of the next illustration, and the position in such a plant of the various tissues already alluded to was entered into. In this case the connections which exist between the strands of these tissues in the stem and those in the leaf were indicated, as well as the course which is followed by the former. Lastly, a palm was selected for the study
of these strands of tissue or vascular bundles in the stem and their passage to the leaves. In each case the internal framework was the part upon which particular stress was laid.

The lectures were illustrated by sketches upon the blackboard, which the lecturer executed in coloured chalks with consummate skill. Several preparations were also exhibited under the microscope.

Provincial Transactions.

PLYMOUTH, DEVONPORT, STONEHOUSE, AND DISTRICT CHEMISTS’ ASSOCIATION.

A special meeting was held at the Foresters’ Hall, Plymouth, on Wednesday, the 9th inst., at 2.30, for the purpose of passing the revised rules as drawn up by the Committee. Present—Messrs. C. J. Park (chair), J. G. Netting, R. F. Roper, Condy U’Ren, R. H. Rendle, H. O. Hodge, A. D. Davey, Green, Weary, Jas. Cooks, F. Maitland, and P. A. Kelly. Subsequently the usual quarterly meeting was held, and after the general business, and the election of three new members, an instructive paper entitled, “Some Suggestions for and a Better Means of Consolidation for those engaged in Pharmacy,” was read by Mr. P. A. Kelly.

In this the author attributed many of the present difficulties of chemists and druggists to apathetic neglect of their own interests. The Pharmaceutical Society was stated to be unfairly charged with not doing what pharmacists themselves should do. Someone had said that chemists sold in pennyworths, and seemed also to think in pennyworths, and this was not altogether inappropriate in certain cases. A consolidation of forces was necessary, and local associations should do more to contribute to this result. All who now grumbled at the Pharmaceutical Society should join its ranks, as they had no just or honest right to complain under present circumstances.

Mr. J. G. Netting thought there was a good deal of truth in what Mr. Kelly had said, which was very apparent in associations, for the utmost apathy was shown in attending meetings. He thought a lot of the ill-success in business was due to chemists being generally almost utter strangers to one another.

Mr. Cooks thought almost the only remedy, to hope for a better state of things in the future, was in association, for the purpose of buying, defence, harmony etc. A series of articles had been running in Pearson’s Weekly how best to run various businesses, written by the respective editors of trade papers, and they one and all advocated associations, for the purpose of buying, controlling retail prices, etc.

Mr. Maitland strongly believed in associations, and that members should not be alarmed if the meetings were occasionally breezy, provided they were not personal, which he greatly objected to.

Mr. Rendle expressed great pleasure at the contents of Mr. Kelly’s paper, and thought there was much in it to take home and digest.

Mr. Park quite agreed with Mr. Kelly as to chemists’ apathy, and believed in fairly strict examinations, as contributing to the safety of the public, not that it gave any monopoly as in some countries; he thought by association chemists might hope to combat the enemies to the trade.

Mr. Roper thought chemists frequently made a great mistake in leaving their shops in the hands of apprentices, as compared with stores which invariably employed qualified men, and that the former should endeavour to be courteous to those customers coming after hours, which gave them an advantage over the latter.

A vote of thanks for his very able paper was proposed to Mr. Kelly by Mr. R. H. Rendle, seconded by Mr. Roper, and carried unanimously.

Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

At the meeting held on the 10th inst., Mr. John Foster, vice-president, in the chair, the following paper was read:—

LABORATORY NOTES AND SUGGESTIONS FOR THE REVISED PHARMACOPHIA.

BY THOMAS DUNLOP.

When I selected the first part of my subject for to-night, I was influenced by two things—first, a remark made by our president after the Court of Session decision in the Tomlinson case, viz., “Now that we know what the law is, we will require to see that we keep our own doorstep clean”—that had reference to our relation to the Pharmacy Act; secondly, a trade advertisement, which, in referring to the prosecution of chemists for selling defective drugs, said: “No pharmacist looks his best when he figures in a police court to defend a charge of selling inferior drugs”—that had reference to our relation to “The Sale of Food and Drugs Act.”

In reading the reports of prosecutions under the latter Act, I have often felt that it was a reflection upon us as educated men when the defence is couched in such words as, “I was not aware of the admixture.” Recently a Sheriff replied to this defence, “It is necessary that when people go to a chemist’s shop, especially, they should get precisely the article they ask for, whatever they pay for it.”

We know how much sophistication is rife, and we ought to make it part of our business to see that our goods are “of the nature, substance, and quality demanded.” This duty would be less arduous, or not at all necessary, were an A1’ brand of drugs and chemicals our only source of supply, but as long as we can get Turkey colocynth, and colocynth pulp—almond oil and almond oil, exotic (which is not almond oil at all), annual and biennial herbane, etc., etc., we will have no end of trouble. The Act says, “No person shall mix or powder any drug with any ingredient or material so as to affect injuriously the quality or potency of such drug, with the intent that the same may be sold in that state, and no person shall sell.” That being law, how does it come to pass that the onus falls on the retailer only?

It is my practice from time to time to examine the
drugs and chemicals that I meet with in the course of business, but during the past few months I have given this more attention for the purposes of this paper, and for that reason I procured trade samples. My examination has been both microscopic and analytical. Speaking generally, everything was good. That being so I will confine my "Notes" to three articles—two of which have been the ground of frequent prosecutions, and the third might become so any day.

Spiritus aetheris nitroei has been specially studied. This article has been the subject of much investigation, and a rock of offence to many a chemist.

In August, 1885, G. E. Perry reported in the Pharmaceutical Journal that spirit which on May 6 contained 4-10 per cent. of nitrous ether, had by July 23 lost 2-33 per cent., whilst the Winchester containing the remainder of the spirit (which had been kept in the cellar), had only lost 52 per cent. Symons, a week later, reported his experience, which was that he kept it almost unimpaired by storing it in small bottles in the cellar—the bottles being corked with paraffin-coated corks—stored thus for thirteen months it still contained 3 per cent. Latest of all are H. W. Jones’ observations at the recent British Pharmaceutical Conference, which were not so much to find how to prevent deterioration as to note the rate at which it occurred. The discussion tended to point to buying in small quantities as the only safeguard.

My observations have been in both directions. The test I used was Proctor’s. I stocked a pint of spirit on Oct. 23 last.

On Oct. 25 when tested it was normal. I then put—

8 oz. into a clear 1 lb. chloroform bottle.
8 oz. " blue "
2 oz. " clear 2 oz. stdp. "
3 oz. " blue 1 lb. "

The first two were placed on the first shelf and 18 ft. from the window, the third was kept on the top shelf and 18 ft. from the window, and the fourth was kept in a dark press.

The first two were tested weekly from Nov. 8 with the following results:—that by Nov. 29 the contents of the clear bottle were useless, whilst the contents of the blue bottle, although below normal, were still usable. By Dec. 27 the contents of the clear bottle gave no reaction when the whole of the test was added, whilst the contents of the blue bottle had only reached the useless stage.

On the latter date the contents of the other two bottles were also examined. In the interval they had been unopened. The contents of the 2 oz. clear bottle were found to be useless, whilst those of the 1 lb. (blue) bottle were still normal, although weaker.

When examined to-day at the end of another fortnight it was unchanged.

The deduction from these observations is that to reduce the deterioration of spiritus aetheris nitroei to a minimum it should be kept in dark coloured bottles excluded from light and heat.

I tested five samples procured in different parts of the city. Results:—One, over normal; one, normal; one, just normal (a day or two would have been sufficient to have put it into a lower grade); one, below normal, but usable; one, quite useless (gave no reaction when the whole of the test was used).

Almond Oil.—I examined eight samples of this oil. Three were English oil; five were exotic. Of the five two seemed to be a mixture of oils.

Exotic almond oil is known to be peach-kernel oil. Its identification is so easy that even although it was substituted for English oil there would be no difficulty in detecting it. In the case of almond oil, no defence can be put forward, as we are not in the case of cera alba, bound to stock an adulterated or substituted article.

Milk of Sulphur.—Sulphate of calcium has apparently now no existence in this except in name. It is not even mentioned in some wholesale price-lists, whilst others quote milk of sulphur as sulph. precip. imp. That being so, proves my argument that if only pure drugs and chemicals were to be had the conduct of our business would be materially lightened.

Five samples examined were all found to be pure sulphur precip. My investigation shows that in one case an impure article has now practically no existence, in another the balance is nearly one to two on the wrong side, whilst in a third (which to begin with may be genuine), in the short space of less than five weeks, it will, with careless keeping, have become useless.

In concluding this part of my paper, I think that an apology to the trade for trespass (?) is unnecessary, as my “Notes” were made simply with the desire to find whether, as far as pharmacy in Glasgow is concerned, its members are doing their best to secure that public confidence which is one of the foundation stones of success: in other words, whether, not only as regards the Pharmacy Act, but also as regards the Sale of Food and Drugs Act, the doorstep is being kept clean without the superintendence of a sanitary inspector.

I will now briefly bring before you “The Suggestions for a Revised Pharmacopoeia” that I have to make. The suggestions do not affect the Pharmacopoeia either by way of addition or deletion, as they deal exclusively with “processes” at present official, which, I think, might with advantage be modified or altered, and in some cases made more explicit.

Actaea Scirra.—Suggestion: Make with bulb “cut small” (not “bruised,” as at present ordered), and, as recommended already, use the acid. acet. dil. 1 in 6, and dilute to 8 before using. Made thus it is less mucilaginous and keeps better.

Glycerin Preparations.—With the exceptions of glycerina amyli, plumbi subacetatis, and tragacanthae (which are special preparations for special uses), they should be of a uniform strength by volume. At present the strength varies from 1 in 4 to 1 in 6. A strength of 1 in 6 would be preferable, and by such a change glycerinum bursae would be improved, the abstraction of 2 oz. of water better adapting it for some of the uses to which it is put, and for which it is unfitted by the addition of such a large proportion of water as was introduced into it in the 1885 Pharmacopoeia. Liquors, essences, spirits,
tinctures, and decoctions have a constant volume strength, and I have failed to see why glycerin preparations should be an exception.

**Infusions.**—The addition of concentrated infusions has been advocated. I dissent from that proposal. I would rather the concentrated infusion had no existence. When a medical man orders an infusion, I think a diluted liquid extract ought not to be supplied. The quality of the (so-called) infusion is impaired by the prolonged exposure to heat to which it has been submitted during concentration, and in the case of drugs containing volatile ingredients, these are dissipated—e.g., inf. buchu, gentian. co., etc. In the present Pharmacopoeia the time of infusing was reduced so as to foster the dispensing of freshly-made preparations, and I think no exception can be taken to the time being too long. There are twenty-eight infusions. Of these five are infused for 15 minutes, 17 for 30 minutes, 5 for 60 mins., and 1 for 120 mins.

In a recent pharmaceutical editorial were the words, "While there is every reason for endeavouring to ascertain methods by which better preparations may be obtained, there is no legitimate ground for ignoring the Pharmacopoeia in respect of what it renders official." It has not been proved that concentrated infusions are "better preparations," and their indiscriminate use is a constant "ignoring" of the Pharmacopoeia.

**Oils (fixed).**—At present we have only "characters" given. I would suggest that "tests" also should be given.

**Olate of Mercury.**—Suggestion: A 20 per cent. strength as better keeping, and dilute with oleic acid or, preferably, vaselin. Ordinary paraffin molasses does not do, as it reduces the oleate. There is a specimen of a 20 per cent. oleate on the table.

**Ointments.**—The ointments having the paraffins as a base are, I think, too hard. The relative proportions might be altered. Not being unctionous, they make a bad combination per se. Mr. Boa, when addressing the Edinburgh District Trade Association, said, with reference to official preparations: "In official medicines we want uniformity—that I assume is the object of having a Pharmacopoeia"; and again, "Preparations sold as pharmacopoeial should be made according to the official processes, unless we want to create misgivings in the minds of prescribers and patients, and give trouble to our fellow-chemists." But if the Pharmacopoeia gives no "process," as is the case with thirteen of the ointments, how can "uniformity" be attained? An ointment made on a slab or in a mortar does not admit of comparison with one made by adding the medicament to the melted base—where that is practicable. The former is always a mechanical mixture; the latter is, in many cases, a solution.

Illustrating this you will find on the table specimens of gall and opium ointment, one made on a slab and the other by adding the powders to the melted benzoated lard. You will also find a specimen in which the opium was infused in the lard (just at the melting point) for an hour, and then the galls added. The latter (as in well-made Dover's powder) shows no trace of the opium, and in practice I am confident it will be more potent as an anodyne. My suggestion as regards this ointment is that the opium should be infused for an hour, with frequent stirring during the time of infusing, and then the galls added and the whole stirred till cold.

**Iodide of Potassium Ointment.**—Suggestion: Triturate the iodide with 1 dr. of glycerin, add the adeps benz. 1., and, lastly, 1 gr. of sodium hypo sulphite (dissolved in 5 m. of water) to each oz. I have never found the carbonate of potassium that is official to prevent the discoloration of this ointment. By experiment I have found that it takes fourteen days for the official ointment to become decolorized. I have also found that the present official ointment is much paler in colour if the salts are triturated with an equivalent quantity of glycerin instead of the water ordered, and becomes colourless in a week. As white iodine ointment is asked for, it does not do to send it out saffron yellow in colour, and as its keeping property is impaired by incorporation with so much water, it should be freshly prepared. The hypo sulphite addition meets both of these difficulties, and the glycerin is certainly a better addition than water to lard. A specimen of the suggested ointment is on the table—it was made to-day.

**Sotasacre Ointment.**—Official ointment made from crushed seeds. Finished product stated to contain "10 per cent. of oil." The oil is the known active ingredient—then why not have the formula? Oil 1, benzoated lard 9? The Edinburgh Roy. Inf. Pharmacopoeia has such a formula, the strength being 1 in 8, and the ointment perfumed with gl geraniu.

There are thirty-three ointments in the Pharmacopoeia. There are specific instructions for twenty, mix thoroughly in twelve, and mix in one. In five of the twenty prolonged maceration in the melted base is ordered. My suggestion for the thirteen (with the exceptions of gall and opium ointment—already referred to—and beladonna ointment) is that the directions given for zinc ointment should be authorised as the "process" for making them.

**Pills.**—The quantities given of the excipients to be used are indefinite in many cases,"about" or "sufficiency" being no criterion of the amount required, whilst in some instances where it is specified it has been found to be insufficient, and yet in every case the exact quantity could have been stated. Where "trescia" is ordered I think "syrups" (B.P.) would be preferable, its consistence being constant and therefore reliable, an element which "trescia" lacks.

Official Excipients.

Pil. aloës et ferri. Confection 4, but 6 required and would give a weaker pill.

Suggestion: Pulv. acac. 1, syr. 2 1/2 = 4 (about). That maintains the official strength.

Pil. aloës et myrrh.—Trescia 1, glycerin sufficient.

Suggestion: Syrup 1, and divide in 4 gr. pills.

Suggestion: Sp. ammon. arom., 3 min. to 2/3, gives a soft good-keeping mass with no tendency to pit. Sample at least six weeks' old.
Pil. plumbi c. opio. Confection, 1.
Suggestion: P. acac., glycerin, and syrup each j.
Pil. rhei c. Treacle about 3 (by wt.), glycerin, 1.
Suggestion: Syrup 1 Fr (by measure) = 2 by weight, and divide into 4 gr. pills.
I have never found conf. rose a suitable excipient for ferruginous or astrigent powders. The pulv. acac. gives the necessary adhesiveness and the syrup and glycerin prevent hardening.

Syrup of Iodide of Iron.—Much has been said and written about the preservation of this preparation.
Said. soln. of sugar, the conversion of some of the sugar into glucose (by boiling), the direct addition of glucose, the addition of diluted phosphoric acid, and the storing of it in amber coloured bottles have each, in turn, been recommended.

My suggestion is the addition of 2 min. (per oz.) of hypophosphorous acid. This has the double advantage of high reducing power and forming a soluble salt.
On the table are specimens of the syrup, made on October 25 last, the other made in April last, which have had the usual exposure in the shop stock bottle since then.

Tinctures.—I have only to refer to two—tr. calumba and tr. opii. The former would be better made with rectified spirit, and the latter by the old Edin. Pharm. process.

Christison says of tr. calumb., “A clearer and finer preparation is made by using rect. sp.” I have confirmed this. I have always made tr. opii by the Edin. Pharm. process, in which I see nothing “not to be encouraged” (as Mr. Alcock said at the Midland Counties Association meeting on November 8 last). Made by that process, and allowed to stand for seven days after mixing the aqueous and spirituous infusions, the mucilage is thoroughly precipitated, and no further separation takes place after the tincture is expressed and filtered.

In conclusion, I may say that in the cases where I have made “suggestions” or recommended additions as preservatives I have done so not from a manufacturer’s point of view, but from that of a pharmacists, and on that account the additions are in infinitesimal quantity, but still capable of producing the desired effect for a reasonable time. I do not think that official preparations should be made in abnormal quantities. Every chemist should make his own galenicals, and, as regards tinctures, store them carefully—by that I mean store them in filled bottles, each of which is emptied when it is opened, ointments, pills, and powders being made frequently to suit trade demands. If this were done there would be fewer difficulties met with, and fewer “improvements” required, as each process would be found to yield a product quite satisfactory for all ordinary purposes.

The limits of my subject are so far-reaching that I have only been able to touch a few of the many points that might have profitably been taken up and more fully inquired into. On this account I have to crave your indulgence for the imperfect and incomplete manner in which it has been dealt with.

Afterwards an interesting discussion took place amongst the members, in which many of the points brought forward by Mr. Dunlop were discussed. All the speakers seemed to agree in making tr. opii after the manner of the Edinburgh Pharmacopoeia. Concentrated infusions were said to be prescribed by some medical men; and they could be made without using heat, or even with heat, and retain all the virtues of their ingredients. Confection of hips was mentioned as an excipient for pil. alois et ferri, which made a good mass with the B.P. quantity. With reference to sp. etheris nitrosi, the fact that it was almost invariably received from wholesale houses at a minimum standard showed the impossibility of keeping it up to proper strength, in however small quantities it was stored, when it had to be retailed in smaller quantities.

One of the members referred to the time when chemists distilled their own, and could use methylated spirit in making it, as productive of more satisfactory results than at present. Mr. Dunlop replied to the observations passed upon his paper, and was accorded a hearty vote of thanks. Samples were exhibited of syr. ferri iodidi, pil. coloalynd co., pil. rhei co., and ung. gallici c. opio, made by the warm process and by the B.P. method, and the specimens were favourably commented on.

Parliamentary and Law Proceedings.

CASE UNDER THE PHARMACY ACT.

ACTION AGAINST AN UNREGISTERED PERSON.

On Thursday, January 10, at the Oldham County Court, before His Honour Judge Jones, Walter Crompton, described as a drug store proprietor, carrying on business at 14, Market Place, Oldham, and 61, West Street, Oldham, was sued at the instance of the Pharmaceutical Society for the recovery of penalties for having kept an open shop for the retail of poisons, contrary to the provisions of the Pharmacy Act, 1865.

Mr. T. R. Grey, barrister, appeared to prosecute on behalf of the plaintiff Society, and the defendant was represented by Mr. H. H. Waddington, solicitor, Oldham.

Mr. Grey said that the defendant was the owner of two shops in Oldham, and the Society alleged that two offences had been committed at each. With regard to the offences committed at the Market Place shop, the defendant had paid the two penalties into court. He had now to prove that the defendant was the keeper of an open shop at 61, West Street. He should call witnesses who would prove that on August 25, and September 1, purchases were made at 61, West Street, of a bottle of Powell’s Balsam of Aniseed, which contained morphine—a poison under the Act. The bottle, when purchased, was wrapped in a hand-bill, upon which was printed “Sold by W. Crompton & Co., Genuine Drug Stores, 14, Market Place, and 61, West Street, Oldham.” He should also prove that the name of the defendant, “W. Crompton,” was printed on the window of the shop at 61, West Street.

Mr. Waddington, interposing, produced a deed dated January, 1894, showing that the business at 61, West Street had been assigned to another person.

Mr. Grey, on examining the document, said he saw
that the business had been sold to the defendant's
brother, who also was unqualified. He complained
that this information had been withheld.

His Honour remarked that there ought to have
been no difficulty on the part of the defendant in
giving that information to the Society, but the
defendant appeared to have obstructed it. In the face
of that document he did not see how the plaintiff
Society could sustain the case, but he should certainly
give them all costs and also certify for counsel.

His Honour then entered judgment in favour of the
plaintiff Society for the money paid into court, with
costs. In the second case—that relating to the
West Street shop—he must find a verdict for the
defendant, but he should give the Society all costs.

Reviews and Notices of Books.

A TEXT-BOOK OF INORGANIC CHEMISTRY. By G. S.

The lectures at South Kensington have long been
famous for their wealth of experimental illustrations,
and we have no doubt that both Professor Frankland
and Professor Thorpe are ready to admit their in-
debtedness to Mr Newth for his services as lecture
示范ator for so many years. This unique experi-
ence has given the author special opportunities for
 sketching out what may be called a systematic course
of elementary chemical instruction, and the present
text-book makes a fitting companion to his 'Chemical
Lecture Experiments,' which were published about two
years ago. Although there is no dearth of elementary
chemistry text-books, and one is inclined to think
that there is scarcely room at present for any fresh
books of this character, Mr. Newth appears to
have succeeded in producing a text-book having dis-
inctive features of its own which will appeal to a
large number of students. Amongst these may be
specially mentioned the originality displayed in the
experimental illustrations of the fundamental facts of
the science. In this respect the author is to be
congratulated on making a new departure which
will be acceptable to older chemists who may
have occasion to glance at an elementary text-
book, and will also be useful to the begin-
ner if he be unable to attend lectures at a well-
appointed institution, in helping him to form some
ideas of modern apparatus. Some of the recent ele-
mentary text-books, in which an attempt has been
made to arrange the elements in their natural periodic
order, have given equal importance to all the elements
alike, and although this may be defended on scientific
grounds, a beginner is apt to become bewildered by
the complexity of the subject, and fails to obtain
clear ideas on the properties of those elements and
compounds which he is most likely to meet with.

Mr. Newth has made a judicious compromise by
dividing his book into three parts. In the first of
these he gives a brief sketch of the fundamental
principles and theories upon which the science of
modern chemistry is built. In Part II. the four typical
elements, hydrogen, oxygen, nitrogen, and carbon,
are studied in detail, and afford an opportunity for
discussing such subjects as water, the atmosphere,
and combustion, at an early stage of the book, whilst
in Part III. the elements are treated according to the
periodic classification. In the introductory portion
the author has given a very good summary of our
present knowledge of the physical properties of
gases and such physical phenomena as are of value
to the chemist in differentiating the elements and
their compounds, the chapters on solution and
thermo-chemistry being especially well written.

The omission of the name of Raoult and all details
of the now important method of determining the
molecular weight of compounds with which his name
is associated will be noted, in the short paragraph
devoted to the effect of substances in solution upon
the solidifying point of a liquid. In Part II. one of
the best sections is that dealing with the atmosphere,
and this subject has been brought well up to date by
a note on the new gaseous constituent discovered by
Ramsay and Rayleigh. There should have been some
mention of sulphur compounds as impurities in
town air, and exception must be taken to the
phrase that potable water is an article of food to
man. Acetylene is found under the title ethine,
although no mention is made as to the mean-
ing of this alternative name, and the significance
of the prefix and the term acetylene is used through-
out in the text. In fig. 68, which is a sketch of an
apparatus for the preparation of copper acetylide
from the products of the incomplete combustion of
coal gas, a condenser should be shown for cooling
the gases before passing into the solution of
ammoniacal cuprous chloride. Under aluminium
the Deville process for obtaining this metal is alone
described, although electrolytic methods are now
of the greater commercial importance, and, as
is usual, several pages are devoted to the Leblanc
soda process and the approximate composition of
black ash and the usual pictures of a salt cake
urnace, while the few lines without any details on
the ammonia-soda process leave the student ignorant
as to the relative magnitude of these rival methods
of alkali manufacture. The possibility of both being
replaced by an electrolytic process is not even
hinted at. After all, these are but minor points,
and can be easily amended in a future edition, which
it is hoped may soon be called for.

A TEXT-BOOK OF ORGANIC CHEMISTRY. By A.
Bernthsen. Translated by Dr. M'Gowan. Second

Professor Bernthsen, of Heidelberg, is to be con-
gratulated on the well-deserved success which has
attended his 'Text-Book of Organic Chemistry,' both
in its English and German garb. In Germany four
editions have been demanded in little over six years,
and Dr. M'Gowan's translation has been so well
received in this country that he has thoroughly
revised the English edition and brought it up to the
standard of excellence which obtains in the last of
the German editions. Many of the chapters have
been more or less re-written, and the sections which
deal with the determination of molecular weights by
physical methods, ketonic acids, di-ketones, the uric acid group, azoles, quinoline, and acridine groups have been much expanded. Since the publication of the first edition there have been several important researches published, which have rendered it desirable to modify some of the sections; thus, for example, the chapters on the sugars and terpenes have been altered considerably, due to the increase in our knowledge of these compounds through the labours of Emil Fischer and Wallach. Kühne's classification of the albumins is also adopted in the section relating to these compounds, and makes the portion of the book relating to the changes which the albumins undergo during fermentation well up to date. The adoption of the new international nomenclature is also a distinct feature of the present edition. At present the authors have, however, wisely refrained from rushing into the new system all at once, and have adopted a compromise which should be appreciated by students during the present transitional period. It is, nevertheless, highly desirable that students should, for example, realise that butane-diol di-acid is a systematic name for tartaric acid which has the approbation of the leading chemists of the world, although we doubt if there are many teachers in this country who have introduced this system into their lectures. It will be seen from the few points which have been alluded to that, as a modern textbook, the present edition is in some respects unique, and it cannot, therefore, fail to find as much favour in this country as the corresponding editions have done in Germany. Dr. McGowan is to be commended on the care which he has shown in editing the book for English-reading students, as it seems to be remarkably free from printer's errors.

Correspondence.

The Atmosphere of the Sun.

Sir,—In an able article on "The Possibility of Life in other Worlds," by Sir Joseph Ball, in the Fortnightly Review for November last, occurs the following sentence:—

"Surrounding that visual globe, the sun, there is an atmosphere of which hydrogen is one of the most prominent components."

If this be the fact, what would be the probable result? May it not rather be inferred that the sun's atmosphere is somewhat analogous to our own, and that light and heat are due to carburetted hydrogen; combustion being supported by oxygen? The late Mr. Proctor demonstrated that the flames emanating from the solar disc are 700 miles in height; how this sublime spectacle can be continued for an indefinite period of thousands of years without diminution, is a problem that no theory of evolution can solve.

Kingston-on-Thames. R. Goodwin Mumbry.

Aqua Chloroformi and Aqua Camphora.

Sir,—My objections to Mr. Elborne's process for making aqua chloroformi (p. 581) are the want of definite strength and probable variability of the product. The strength and the rate of saturation would vary according to temperature. The time (twenty-four hours) required to make a saturated solution by his process is too long. By the B.P. process, the quantity there ordered can be made by agitation for twenty seconds, and the product is definite in strength. It might be prepared, as is frequently done when chloroform is used for preserving organic solutions, by mixing the chloroform with an equal volume of rectified spirit before addition to the aqueous fluid. By this mode the chloroform dissolves more readily and without much agitation. I have elsewhere (vide Extra Pharmacopoeia) objected to aqua camphora being prepared by the B.P. process—the origin of Mr. Elborne's idea—and suggested that it should be of definite strength and made by using a strong alcoholic solution of camphor. The variation of strength of aqua camphora B.P., owing to its preparation at a higher or lower temperature, is such as to be noticeable by a patient taking a mixture containing it. I think if aqua chloroformi were prepared so as to contain exactly 1 volume in 200 volumes, and aqua camphora 1 in 1000 volumes (cum spiritu, as above), more generally satisfactory results would be obtained. Spirit of camphor B.P., too, should be 1 in 10 volumes, and a preparation equal to Rubini's should also be official.
Dose of aqua chloroformi.—I would further urge against the complete saturation of this the fact that as a vehicle it is at present too strong for most persons to be taken undiluted. They complain that it causes unpleasant eruptions. I in 400 volumes is mighty enough to be inhibitory to most germ growths. We rarely have more than a fluid drachm of spirit of chloroform prescribed in a 6 or 8-oz. mixture. This makes a chloroformic solution less than 1 in 400 volumes. As chloroform water is generally used as a vehicle only, it would be better to state the dose as “8 to 8 fluid drachms, diluted.”

10, New Cavendish Street, W. WM. MARTINDALE.

Sir,—In your issue of the 19th instant, page 581, is described a rather elaborate process for making the above. Permit me to describe a much shorter one. I mix the chloroform with half the quantity of water required, and violently shake it until the chloroform is in a state of very minute division; the remainder of the water is now immediately added, and after shaking for a minute or two a perfect solution results. In making medicated waters I find the best results are obtained by following the plan devised by the late Mr. Bailly, of Margate, and described in his ‘Physician’s Pharmacopoeia,’ page 2, published by Messrs. J. and A. Churchill. PERCY WELLS.

Cambridge Gardens, North Kensington.

THE REMUNERATION OF PHARMACISTS.

Sir,—I am very pleased with everything contained in the letter from “Bistro” in last week’s Journal, and he must be congratulated on his sound method of reasoning, but there is another side also to this much vexed question, with which I am about to deal. The remuneration of pharmacists and company trading to a certain extent go hand in hand. Some time since I was anxious to qualify and it cost me no end of money, time, worry, and loss of health; and what is my reward? My certificate has not up to now brought me in a single penny, because I have done the usual kind of work which I did regularly when unqualified. I will give two instances that occurred to me during the last few days. The principal in the first instance says: "You are qualified, oh, an unqualified man can manage the place just as well for me!" Case number two, a pound a week with small commission and two unfurnished rooms. Now, is it not time to put the screw on tight after this? I have the greatest respect for our Society, and I am grieved to see that chemists are not so liberal towards it as they might be. I should like to ask two questions, as my eyes have been opened lately. How many hundred unqualified men are setting the Pharmacy Act at defiance in London only? How many thousands are doing the same throughout England, Scotland, and Wales? This, I admit is not a consoling reflection; but it is nevertheless true—and many readers no doubt will smile when they read this, and if they felt so inclined, could substantiate this statement—knowing it to be one of the greatest evils with which we have to contend. The common law of England looses none of its dignity because it bring down a heavy punishment on the wrong-doer; and the same can be said of the Pharmacy Act of 1868. I am seriously considering whether it would not be better for me to hire a piano-organ, with an announcement in large type—"Ladies and gentlemen, I am a qualified chemist. There is no further necessity for my services, as the work is now done by unqualified men who break the law with impunity." Now, fancy turning the handle with such strains as "'E damno where o're ao!" The evils that exist are bad enough at present, and the future of pharmacy, as predicted by some to be a very brilliant one, will exist in the flight of imagination only unless those obstacles are removed. The motto and passwords should be to treat all in the same way, whether they belong to the Society or not. If I break the law in any way, I expect to suffer; if I set the Pharmacy Act at defiance, I must also suffer. I desire in every way to be loyal to the Society, and if my brother chemists would do the same we should hear very little of company trading, and our future idealistic state be not a dream but an accomplished fact, which we cannot expect by a process of natural evolution.

J. DINELA.

"HABENDA RATIO VALETUDINIS."

Sir,—You may perhaps deem it worthy of note that in Caesar’s "Gallic War," book 7, chap. 1, line 17, there occurs a sentence which is directly illustrative of the full meaning of our pharmaceutical motto—"Imprimis rationem esse habendam dicunt . . . . . at Caesar ab exercitio inter cladem" etc. "They say that such care must be paid to this . . . . . that Caesar be cut off from his army" etc. In the light of this I think the full translation of our motto is "We must pay special attention to health." Nor may we forget the full force of valetudo, from "valet," implying not simply health but strength and safety, as valet! = fare-well! So when our children inquire of us what mean these words, we may truly answer that, "We (pharmacists) must pay special attention to the health and safety of the public."

"Nor do I name the men of common rout, That wandering loose about Grow up and perish, as the summer fly, Heads without name no more remember'd, But such as Thou hast solemnly elected, With gifts and graces eminently adorn'd To some great work, Thy glory, And people’s safety, which in part they effect."

MILTON—"Samson Agonistes."

West Marylebone.

J. C. H. ASLOP.

ADULTERATION OF BEESWAX.

Sir,—Having recently returned from Smyrna, where I had the occasion to analyse many samples of beeswax, and having noticed an article on the same by Mr. John C. Umney in the Pharmaceutical Journal of December 22, 1894, I should like to make a few remarks. I quite agree with Mr. Umney that the testing of beeswax should be carried further than that stated in the British Pharmacopoeia. Whilst in Smyrna I examined many samples of beeswax, and only found one free from adulterants. Although the adulterant was stearin which I generally found, yet I may say it is an easy matter to overlook the same, if beeswax is not too largely sophisticated and simply the tests of the British Pharmacopoeia be carried out.

RICHARD B. G. SILVERSTEDTS.

Newcastle-on-Tyne.

NOTICES AND ANSWERS TO CORRESPONDENTS.

Mr. Barron, the local secretary for Cheltenham, desires to express his thanks for an anonymous donation of 5s., received on behalf of one of the unsuccessful candidates at the recent election of annuitants under the Benevolent Fund.

THE DISCOVERY OF OXYGEN.

(Continued from page 525.)

CARL WILHELM SCHEELE.*

Born at Stralsund on December 9, 1742, Carl Wilhelm Scheele was a Swedish subject, though of purely German descent. He almost invariably spoke and wrote in German, and the patience, care, and accuracy manifested throughout the whole of his work are in marked accord with what has been done since by German chemists. His father was a tradesman of but limited means, and Scheele, being the seventh in a family of eleven children, enjoyed but limited educational advantages. He was apprenticed to a Gothenburg pharmacist at the age of fourteen, and subsequently acted as an assistant in Malmö, Stockholm, and Upsala, respectively. In 1775 he was nominated "provisor" of a pharmacy at Köping, which he conducted until his death in 1786.

Classical studies did not interest Scheele, and he never studied mathematics. During his apprenticeship, however, he mastered all the standard works on chemistry then available, and planned experiments, the execution of which was of necessity postponed until late at night. Gradually he acquired a considerable knowledge of the properties of chemical substances, besides laying the foundations of a manipulative skill which has probably been unsurpassed by any scientific investigator. He made every compound of the numerous substances he discovered that was possible with the means at his command, and overcame the difficulties caused by the lack of suitable apparatus, by devising ingenious appliances which helped in the elucidation of most abstruse chemical problems. His laboratory has been described as consisting of a furnace, alembic, sand bath, crucible, some phials, ordinary tumblers, glasses, and a few bladders to contain gases.

There is now definite proof that Scheele is entitled to be credited with actual priority in the discovery of oxygen (fire-air) by about two years, though his printed account of it did not appear until two years after that of Priestley. Scheele's laboratory notes, preserved in the Royal Academy of Science, Stockholm, show that, prior to 1773, he had obtained oxygen from mercuric oxide, potassium and magnesium nitrates, silver and mercury carbonates, and other substances. He also discovered chlorine, ammonia, hydrochloric, hydrocyanic, and hydrofluoric acids, and investigated their properties. Manganese and baryta he showed to be individual substances, whilst he investigated the nature of alum, clay, quartz, and silice, and discovered glycerin and several organic acids—citric, gallic, lactic, malic, mucic, oxalic, tartaric, and uric. Indeed, his discoveries were so numerous and varied as to cover the whole range of chemical science. But it was not in recording facts alone that he excelled, for he also invented many new processes, and, by initiating the use of characteristic reactions to detect and separate allied substances, was one of the first to put chemical analysis upon a definite basis.

Scheele on Air and Fire.

The record of Scheele's experiments on air is found in his 'Chemische Abhandlung von der Luft und dem Feuer,' published in 1777, and translated into English by J. R. Forster in 1780.* At the outset the author remarks that the object and chief business of chemistry is to skillfully separate substances into their constituents, discover their properties, and compound them in different ways, and that the difficulty of performing such operations with the greatest accuracy can only be unknown to those who are entirely or insufficiently acquainted with the subject. He then proceeds to explain the necessity of a knowledge of fire, and states that he undertook a multitude of experiments in order to fathom that phenomenon as fully as possible.

Air he describes as the fluid invisible substance we breathe, which surrounds the whole surface of the earth, is very elastic, and possesses weight. Mixed with it are watery vapour and another elastic substance resembling air, called aerial acid (carbon dioxide), which owes its presence to organised bodies destroyed by putrefaction or combustion. Such substances may consume a part of the air or perceptibly increase its bulk, or neither increase nor diminish a given quantity of it. With regard to the general properties of atmospheric air, fire must burn for a certain time in a given quantity of it; if, during combustion, the fire does not produce any fluid resembling air, the quantity of the latter must be diminished between a third and a fourth part; air must not unite with common water; all kinds of animals must live for a certain time in a

* For more extended biographical accounts of Scheele see the *Pharmaceutical Journal* for January 14, 1868, and Thorpe's 'Essays in Historical Chemistry.' (Macmillan.)

VOL. LIV. (Third Series, Vol. XXV.), No. 1283.

* A modern translation of the essential portions of this work constitutes one of the Alembic Club reprints (W. F. Clay, Edinburgh).
confined quantity of it; and seeds, in a given quantity of similarly confined air, must strike roots and attain a certain height with the aid of some water and a definite heat. When, therefore, a fluid resembling air had not all these properties, Scheele was satisfied that it was not ordinary air.

Air, according to him, must be composed of two kinds of elastic fluids, as proved by the diminution in bulk of a confined quantity of it that occurred when various substances were exposed to its influence, whilst the same experiments proved that phlogiston, the simple inflammable principle, was present in each case, since he says it is known that the air strongly attracts to itself the inflammable part of substances and deprives them of it, and by the transference of the inflammable substance to the air a considerable part of the latter is lost. Further, a given quantity of air can only unite with and saturate a certain quantity of the inflammable substance. Whether, however, the displaced phlogiston was still present in the air left behind in the containing vessel, or whether the air that was lost had united and fixed itself with the substances experimented on, remained a moot point. Experiments were performed, therefore, with a view to solving the problem.

RESEARCHES ON AIR AND FIRE.

Phosphorus heated in a closed flask was found to ignite and form a white cloud which settled upon the side of the flask like white flowers, consisting of the dry acid of phosphorus (phosphorus pentoxide), and on opening the flask under water, a certain quantity of the liquid was forced in by the pressure of the external air. A similar result occurred when pieces of phosphorus were simply allowed to remain in a closed flask for several weeks.

Inflammable gas (hydrogen) was generated by acting upon iron or zinc filings with diluted oil of vitriol, in a bottle (Fig. 3, A) through the cork of which passed a glass tube. This bottle was placed in a vessel, B, containing hot water, and the issuing gas was ignited, after which the flask, C, was inverted over the flame, with its mouth under the surface of the water, which at once began to rise into the flask until it reached the point, D. When, however, the flame went out the water was entirely driven out of the flask again and, since the space up to D equaled one-fifth the total contents of the flask, it was thus proved that one-fifth of the air formerly present had been lost during the experiment.

A burning candle was next proved to cause a similar loss of air. A mass of wax, resin, and turpentine, melted together, was pressed upon the bottom of the dish, A (Fig. 3, B), and a thick iron wire fastened in it, which reached to the middle of the flask, B, and bore at its upper extremity a small wax candle, C. The candle was lighted; the flask inverted over it and pressed deeply into the mass, and the dish filled with water. When the flame was extinguished and the apparatus cool, the water was admitted into the flask, and the loss of air again noted. Burning spirit of wine or glowing coals were found to produce a similar effect. In these cases the bulk of air was not so perceptibly diminished as in the previous experiments, but it was found that this was due to the addition to the contents of the flask of the aerial acid formed during combustion.

Further experiments proved that when the two kinds of elastic fluids constituting ordinary air had been separated "by means of phlogiston," they could be recombined to form air. Before arriving at this conclusion Scheele had first to face the problem as to the destination of the air apparently lost during the preceding experiments, and then to prepare the two constituents of the air in a pure condition. He objected to the theory that by the union of air with phlogiston it became lighter, phlogiston being a substance—according to him—which always presupposed some weight.

On fuming acid of nitre (nitric acid) being distilled, at first it went over red, then became colourless, and finally it became red again. The receiver was at this point replaced by a bladder containing thick milk of lime to prevent corrosion and the distillation then proceeded with. The bladder gradually expanded by the pressure of evolved gas, due to

Fig. 3.—Apparatus employed by Scheele in his experiments on Air and Fire.

the decomposition of the acid, and this gas was found to support the flame of a candle much better than ordinary air. One part of this gas mixed with three parts of that kind of air (the residual nitrogen) in which fire would no longer burn was like ordinary air in every respect, and since the newly discovered air (oxygen) was found to be necessary for the origination of fire, Scheele named it “fire-air,” whilst the inert constituent of ordinary air, left as a residue after burning combustible substances, he termed “vitiated air” (nitrogen).

APPARATUS EMPLOYED BY SCHEELE.

His method of transferring gases from one vessel to another is worthy of description. Soft bladders oiled inside were employed to generate many gases and to collect others. In the latter case a bladder containing milk of lime to absorb any aerial acid

* These were all instances of simple oxidation, liver of sulphur, nitrous air, oil of turpentine, etc., being experimented upon.
(carbon dioxide) evolved, was tied to the neck of a retort (Fig. 4, C). When a gas was to be generated in a bladder, AA (Fig. 4, D), the chalk or other substance was placed at the extremity of it, the string n was tied just above, the diluted acid then poured in, and the bladder again tied with string at C. The string n was then untied and the acid so allowed to come in contact with the substance, the evolved gas inflating the bladder. To transfer the gas from the bladder to a bottle or other vessel, the latter was filled with water and fitted with a cork. The end of the bladder was then tied firmly over the bottle neck and the whole inverted. On grasping the cork through the bladder it could be withdrawn sufficiently to permit the gas and water to exchange places, after which it was replaced, the bladder detached, and the bottle placed with its neck under water. Slight variations on these operations were necessitated in certain cases, but the above fairly represents the simple general methods employed by Scheele in his experiments on air and fire.

Fig. 4.—Apparatus employed by Scheele in his experiments on Air and Fire.

Other substances from which Scheele afterwards prepared his fire-air, were manganese and oil of vitriol, magnesia, nitre, red precipitate, arsenic, silver, magnesia and mercury nitrates, etc., etc. He proved that the gas obtained was in all cases identical with the constituent of ordinary air that disappeared in his earlier experiments; the effects observed on repeating those experiments, with the fire-air substituted for ordinary air, being similar but, naturally, more pronounced. He says "this fire-air is just that air by means of which fire burns in common air; only it is there mixed with a kind of air which seems to possess no attraction at all for the inflammable substance, and this it is which places some hindrance in the way of the otherwise rapid and violent inflammation. And, in fact, if air consisted of nothing but fire-air, water would surely render small service in extinguishing outbreaks of fire."

Physiological experiments were also performed with rats, flies, bees, caterpillars, butterflies, peas, etc. In the case of animals it was observed that air was partially converted during the respiration of animals into aerial acid. An experiment with a bee was performed in the apparatus represented in Fig. 3, E. Into the bottle A, which had a small hole at the bottom, was put a piece of unsalted line, and the mouth was then closed with a cork through which passed a tube n. The inverted glass C contained a live bee and some honey to serve it as food, and the connection with the bottle was made air tight by means of a ring of pitch. The bottle A was then stood in a vessel of water n, and weighted to prevent it from floating. A little water rose into the bottle through the small opening every day, and after seven days the water had risen to the line x and the bee was dead. The aerial acid formed was, of course, absorbed by the lime water, and it was noted that when two bees were enclosed the same quantity of air was converted into aerial acid in half the time. The other insects caused a similar effect, as did also fermenting peas, and Scheele was able to prove that the fire-air only was thus converted into aerial acid.

Plants were found to be unable to grow in pure fire-air, though animals existed longer in pure fire-air than in ordinary air. Scheele also assumed that there was a difference between animals and insects in this respect, being puzzled, apparently, by the part played by vitiated air (nitrogen) in the respiratory process. He observed, "it is the fire-air by means of which the circulation of the blood and of the juices in animals and plants is so fully maintained. Still, it is a peculiar circumstance that blood and the lungs have not such action upon fire-air as insects and plants have, for the latter convert it into aerial acid, and the former into vitiated air." Fire-air being found by Scheele to be soluble in water, he suggests that it must be as indispensable for aquatic animals as for those which live upon land. "They must draw it into their bodies, and convert it either into aerial acid or into vitiated air."

Comments on Scheele's Work.

It is clear that Scheele besides discovering oxygen independently and, as it now appears, first in point of time, obtained very similar results to those of Priestley, though he proceeded about the work in a much more systematic and exact manner. He did not discover so many new chemical substances as Priestley, but opened up much new ground. An equally strong supporter of the phlogiston theory with his English discoverer, he was also led to erroneous conclusions by his own exact observations. On finding that when air appeared to combine with the phlogiston in phosphorus, metals, and other bodies (i.e., lost oxygen), the residue became lighter than common air, he inferred, as has been shown, that a portion of the common air must have disappeared, and that, accordingly, the air must consist of two gases. One of these he assumed to be capable of combining with phlogiston, and he concluded that it must be heat or fire which escaped through the glass. It does not appear that he ever realised that ordinary air consists of two distinct gases, oxygen and nitrogen. Like Priestley, he seems to have regarded the latter as an impure variety of his fire-air, rendered so by the addition of phlogiston.

It is pointed out by Thorpe that the delay in the publication of Scheele's work on air and fire tended to prevent a proper recognition of his merit among his contemporaries. His extraor-
dinary insight is described as instinctively seizing on what is essential, and "no man was ever more staunchly loyal to the facts of his experiments, however strongly these might tell against an antecedent or congenital hypothesis." His work was more qualitative than quantitative, or he would probably have overturned the phlogiston theory earlier than that was done by Lavoisier. As in Priestley's case, however, others made use of his facts to demolish that theory by which he could alone explain them, and to which he vainly imagined they lent so strong a support, and "it must be admitted that he was wanting in the faculty of co-ordination, grasp of principle, and power of generalisation, that so strikingly characterised Lavoisier."

Scheele was yet the greatest chemical discoverer of his age. "An obscure apothecary, living a solitary sedentary life in a small town on the shore of a Scandinavian lake, hampered by poverty and harassed by debt, hypochondriacal, and, at times, the victim of the most depressingly melancholy—he yet succeeded by the sheer force of his genius as an experimentalist, and under the influence of a passion which defied difficulty and triumphed over defeat, in changing the entire aspect of a science. No man ever served chemistry more loyally or with a purer, nobler, more disinterested devotion than Scheele." *

(To be continued.)

THE MANUFACTURE OF MILK SUGAR.

BY CHARLES A. SIEBEE, B.S.C.

In these days of lactated food and tablet triturates the use of milk sugar is increasing by leaps and bounds; at a rough estimate the United States consume annually one and a-half million pounds.

Ten years ago practically all the United States supply came from Switzerland and Germany. To-day our best manufacturers actually export.

The technical information that we are enabled to gather from books is exceedingly scant, for the simple reason that this product has been in the hands of the "black art brigade." Perhaps this is as well, since the results until late years have been of such quality as to make print unnecessary.

As primary product, whey is used. This is obtained from the cheese districts of Northern New York State, Ohio, and Illinois. As a general rule the manufacturer allows the farmer five cents per hundred pounds of whey as it comes from the cheese factory or creamery, if in good condition (not soured). This price is not exorbitant, but, as the manufacturer is in the hands of the farmer, sour or sweet he has to take the whey. Now it so happens that, cent per cent, whatever the acidity may be, it represents a corresponding loss to the maker, plus a deal of extra labour.

The first part of the process consists in making "raw sugar," and must be conducted next to the cheese factories, as every minute's delay promotes souring. The whey is pumped or run into steam-jacketed iron tanks holding about 600 gallons each and technically called "defecators."

Steam is turned on and the heat kept at 190° F.,

* Thorpe, 'Essays in Historical Chemistry.' (Macmillan.)

when most of the uncurdled milk, fat and casein are thrown out. The whole is allowed to stand, and the clear liquor, after being drained into a lower defecator, is treated with lime or chalk, boiled, skimmed, and concentrated either in open air or vacuum pans.

The solids, skimmed and drawn off, are dried and ground, making valuable ingredients for poultry-food or an adjunct to dog-biscuits.

Nature has so contrived that where milk is cheap, coal is dear; and, as the latter is the more expensive item, the manufacturer has to ship the concentrated whey or crude sugar to considerable distances.

In practice it is usual to effect concentration to one-fifth the original bulk of whey, or 15° B., as it is less liable to decomposition or crystallisation at this strength. Yet a source of waste is frequently present here, as of necessity this syrup has to be shipped in barrels. Nature and railroad employees then join forces in their attempts to reduce profits, as what the sun does not burst the latter succeed in staving in. I have seen nine empty barrels out of a shipment of fifteen.

Arrived at the refinery the barrels are rolled to the dumping-tank on ground floor, emptied, steamed, and sent to the cooper's shop. The syrup is boiled, and pumped or forced to the top floor, boiled in defecators, lime added, skimmed, bleached through charcoal, filtered, run into vacuum pans, concentrated to 30° B., and finally run into crystallising pots and allowed to cool.

On the following day the crystals are poured into centrifugal machines, drained, washed, and placed in the drying-room at a temperature not above 120° F. In case "CC" sugar is required, the fairly concentrated liquor is run into wooden vats furnished with strings or wooden strips four to six inches apart, and allowed to crystallise slowly.

Of necessity I have had to give the refining process hurriedly in order to present a general idea.

In practice things do not go so smoothly, as the troubles begin from the moment the syrup arrives at the refinery.

Previous to detailing these, I shall make myself better understood by saying that pure milk sugar must be absolutely white, make a clear and bright solution when boiled, stand sulphuric and chlorine tests, leave no ash on incineration, and, above all, be free from smell.

Considering that raw syrup is never twice the same, chemically, and that its physical properties range from yellow to muddy black, there is a fund of trouble in store for the operator.

In the first place, the amount of lime necessary for defecation has to be determined, as lime and litmus are dangerous agents in the hands of the man in charge of the defecators. The colouring matter is likewise noted and only the necessary quantity of charcoal used, as too much means loss of sugar and too little ensures a coloured product. Most difficult of all is to get the solution bright. If not bright, no matter how slight the cloudiness, the albuminous matter in suspension will decompose, and the sugar will possess a characteristic offensive odour.
The vacuum pans have to be watched carefully, the syrup getting "wild" at times, when loss is incurred. The centrifugal operations must be watched closely; sufficient distilled water must be used to wash out all mother liquor, but not enough to reduce the yield materially. The sugar should not contain more than 5 per cent. of moisture on leaving this machine.

 Grinding is best effected in large pebble mills provided with exhaust air and chamber for impalpable powder.

 Revivification of charcoal is conducted in much the same style as in ordinary sugar refineries. The mother liquors are calculated and rereckoned.

 A 5 per cent. whey at the cheese factory yields 2% per cent. at the refinery. The majority of makers do not exceed 2½ per cent., and their product is inferior to that of those who work on a scientific basis.

 To inform the majority of manufacturers that they need a chemist and a laboratory would be waste of time, and as a result of this lack of competent oversight these houses are gradually going under.

 Milk sugar is as much in need of intelligent and practical treatment as any other sugar; the first to recognize this were the American Lactose Co. and the National Milk Sugar Co. As a result, European products do not equal our best brands in look or quality.

—Bulletin of Pharmacy.

SPECIALISM IN PHARMACY, BEGOTTEN BY PROGRESS IN BACTERIOLOGY.

Despite its very speculative character, much interest attaches to the forecast made by Dr. Josef Schrank in his address on the future of pharmacy, delivered at the last gathering of German scientists and physicians in Vienna. Bacteriological remedies for disease give to-day such a promise as they have never given before; their general adoption cannot fail to exert an influence on pharmacy; and the present world-wide discussion of the antitoxin treatment for diphtheria bids the pharmacist reflect on the manner in which his interests are to be affected. Mere conjecture, under the circumstances, is better than a needless apathy.

Pharmacy and bacteriology first came in touch when the aseptic treatment of wounds began to prevail. Shortly thereafter, Medicine demanded that the fluids for subcutaneous and intravenous injection be administered sterile. Now it is probable that pharmacy will be greatly modified by the future use of agents imparting immunity, and pharmacists will be required to supply immunised blood-serum and alexines, tannin solutions, chemicals, and culture media.

Where the physician lacks time for the bacteriological examination of blood, pus, sputum, urine, and the like, the pharmacist will find lucrative and honourable employment.

Dr. Schrank asserts that the medical curriculum of the future must be made to comprise hygiene, food-investigations, bacteriology, and that portion of veterinary medicine needed in the production and testing of bacteriological remedies. Paré passes, the office of the apothecary must expand till it comprehend the manufacture of bacteriological remedies, the testing of foods, and the general labour required as a preliminary to diagnosis. The next step must be the establishment of distinct classes of apothecaries—pharmaceutical specialists—according to their individual functions. We shall then have the Dispensing Specialist, the Food and Water Specialist, the Urologist, the Pharmaceutical-Bacteriological Specialist, etc., etc.

It is incontestable that pharmacy will be affected by the advances in bacteriology; those advances have already made themselves felt in almost every drug store, and should the much-discussed antitoxins fulfil their promise the druggist will become their natural and proper purveyor. Beyond this point, however, the Dr. Schrank's forecast is purely speculative; the production of the new remedies will at once be undertaken by the large manufacturing laboratories, or by the government, never by the pharmacist. Fancy the retailer of the future dividing his time between the dispensing-room and the bacteriological wing, preparing his own cultures, making his own injections into the animals purchased at great expense, observing the physiological reactions, tapping the blood from the animal, and finally decanting the curative serum into his own phials! The pharmacist in the past has never tried to make his own vaccin, nor will he be more likely to manufacture antitoxin in the future.

There is no reason why the educated druggist should not become the expert food- and water-analyst or bacteriologist, thus creditably enlarging the scope and income of his labour. But the first essential is a thorough and suitable education. At the present time it is useless in the United States to urge such work on any save a small body of accomplished apothecaries. Sanitary and urinary analyses, bacteriological determinations, require an amount of learning which we have no right to expect from any man save the avowed specialist. We do not want to see the courses in pharmacy so arranged as to give the student a smattering of many things—we want first to see solid instruction in the indispensable few:—pharmaceutical chemistry, botany, microscopy, materia medica, pharmacognosy, and practical manipulations. When this foundation has been solidly built, the desired superstructure may be added. Any other course will accomplish precisely the mischief which is now so obvious in medicine—specialism run mad—specialists galore—leaping from the college into the specialty and assuming the airs of the expert ere possessing the experience of the general practitioner. Specialism should be the natural, unforced outgrowth of general practice, whether in medicine or pharmacy. From any other may the Lord deliver us!—Bulletin of Pharmacy.

MEDICINE STAMPS DUTY.

The duty paid for medicine stamps during the past four years was as follows:—

NOTES ON RECENT SCIENTIFIC INVESTIGATION.

DETERMINATION OF THE PURITY OF LIQUIDS.—Having been engaged in purifying a number of pharmaceutical products, R. Pictet has sought for some definite means of ascertaining their purity, and finds that in the case of liquids, the direct observation of the temperature of their critical points affords a very sensitive test (Comp. rend., cxx., 48). This temperature varies from ten to sixty times more than that of the boiling point in the case of a given liquid under similar conditions. The method adopted was to take a series of very pure liquids and determine their boiling points, noting the height of the barometer, and then to determine the critical points by means of a sensitive thermometer. A few drops of alcohol, aldehyde, water, etc., were then added to the pure liquids, and the boiling and critical points again observed. A tube of 5 Mm. external diameter, 3 Mm. internal diameter, and 45 to 50 Mm. long was filled with the liquid under examination. A portion of the contents was then evaporated, and the tube sealed by means of the blowpipe, so that it was one-third full of liquid, and the remaining space occupied by saturated vapours. The tube was next placed obliquely in a small rack, side by side with a very sensitive thermometer, in the centre of a thin sheet-iron cylinder having two openings fitted with micas. A similar, larger, cylinder surrounded this, and was warmed from below by a multiple gas flame, the current of heated air passing through a series of wire gauze partitions which divided the enveloping space. The whole apparatus was finally enclosed in a third sheet-iron cylinder, covered with asbestos, and arranged so that the tubes could be readily observed through the three pairs of windows. The stem of the thermometer passed through openings in the three cylinders, and it was possible to note distinctly the tenth of a degree. Chloroform, chloroethyl, and pental were the liquids examined. The temperature was first allowed to rise slowly to the critical point, when the meniscus suddenly disappeared, and very characteristic gyratory movements were visible throughout the length of the tube. The temperature was then gradually lowered until the transparent interior of the tube became suddenly opaque, the minute particles of liquid collecting at the bottom and the meniscus reappearing. On warming again, and after several trials, a temperature was found at which within one-tenth of a degree the meniscus was observed to disappear and the mist become visible. This mean temperature is that given as the critical point in the following table:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Critical Point</th>
<th>Difference in b.p.</th>

<td>-1°7 &lt;0°-1</td>
</tr>
</tbody>
</table>

In taking the boiling point it was found necessary always to immerse the thermometer to a uniform depth at the same place, the same vessel being employed and heated by a flame of uniform power. The addition to a liquid of others more volatile and readily soluble lowered the temperature, as when aldehyde was added to pental. On the other hand, the addition to chloroform, boiling at 61°, of the less volatile alcohol, equally lowered the temperature of the critical point. Chloroethyl, which boils at +11°, had its critical point raised 6° by the addition of alcohol, which boils at 78°-8. It is difficult, therefore, to deduce a general law.

ANTIMONIC ACID.—Serono has shown that the supposed pyro-antimonoxonhydrate does not exist. When antimony trisulphide and aqueous potash are boiled together, and the clear liquid is then boiled with a concentrated aqueous solution of copper sulphate, a white precipitate is thrown down on the addition of acetic acid, which was thought to be pyro-antimonoxonhydrate, Sb₂O₃·2H₂O. This precipitate on examination proved to be ortho-antimonic acid, Sb(OH)₃. The reaction depends on the formation of copper oxide and potassium sulphantimonite and subsequent oxidation of the sulphantimonite with formation of potassium antimonite, which on the addition of acetic acid, yields ortho-antimonic acid which is precipitated (Journal für prak. Chem., LI., 97).

GRAPHITE FROM IRON.—Having studied the graphites obtained in a variety of ways, and shown that a number of metals can displace carbon in this form from iron, H. Moissan has compared the different varieties of graphite liberated from the latter metal under different conditions of temperature and pressure. He finds that, at the ordinary pressure, the graphite formed is purer, as the temperature becomes more elevated, besides being more stable in the presence of nitric acid and potassium chlorate. The effect of the pressure on the crystals and masses of graphite is to give the latter the appearance of a fused mass. The small quantity of hydrogen always present in graphite diminishes in proportion as the purity of the graphite increases (Comp. rend., cxx., 1245).

DIASTATIC FERMENT IN PLANTS.—From experiments on seedlings of Canna, Platanus, Phanmelus, Begonia, etc., Dr. J. Grüss concludes the existence in seedlings of a soluble diastase which is capable of diffusion through the cell-wall in the same way as sugar. It appears to pass, with maltoce, out of the cotyledons into the stem; for the removal of the cotyledons diminishes the amount of diastase in the stem. The quantity of diastase present was ascertained by its action on starch, the iodine test being used to determine the extent to which the starch had been destroyed. The penetration of the diastase into the substance acted on is accompanied by a simultaneous change in the latter, and to this process the author applies the term "alloanalysis." The action of the diastase on the reserve cellulose in the seed of the date is very slow, and ends in its transformation into soluble products, probably mannose. It is by this action of diastase that the absorption of reserve cellulose takes place in the germinating date (Fringhelms' Jahrbuch für wissensch. Bot., 1894, pp. 379-437, and Sitzber. Vers. deutsch. Naturf. v. Aerzte, 1894).
The Council ought also to have power, he firmly believed, to erasure from the Register any chemist who was proved guilty of misdemeanour, in the same way that medical men and lawyers who were found guilty of improper and unprofessional conduct were erased.

On the subject of training young men for the calling of chemists he contended that it was of the utmost importance that they should have a thorough education. The policy of encouraging errand lads to cram themselves with sufficient knowledge to enable them to scramble through the examinations was to be deprecated. Such a practice was not only bad for those who were already in the trade, but was a delusion to the persons most directly concerned. After expressing regret that a larger number of the students did not subject themselves to the Major examination, but were content with the privileges they gained by passing the Minor, Mr. Cartwright stated that they must be prepared to abide by the condition of things which prevailed in the trade, and to ask those who had not passed the Pharmaceutical examinations to come in and join them to a greater extent in the management of the affairs of the general body.

To accomplish that end they were quite prepared to go to Parliament with what they hoped would be a non-contentious Bill. He was afraid, however, that nothing could be secured from the Legislature unless the Society could say that it had at its back a majority of the chemists of the country. They must also begin, as other bodies had already begun, to consider the interests of their craft in connection with the great political interests of the country. They must approach parliamentary candidates on matters affecting their trade and show that they had some claim to consideration. They were powerful for defence in the House of Commons, but not powerful enough for legislative purposes.

On the motion of the Chairman, seconded by Mr. Taylor (Bolton), the meeting resolved, with two dissentients, that the Society deserved the support of the trade in its efforts to carry on the existing laws and to promote further legislation. It was also resolved on the motion of Mr. Kirby, seconded by Mr. J. Rymer Young, that the consolidation of the Pharmaceutical Society would be greatly furthered by the removal of the limit as to the number of chemist and druggist members upon the Council.
publication of this official book, and it is liable to
ease general attention that the Register is legal
evidence that the persons specified in its pages are
registered conformably to the Pharmacy Act, and
are therefore entitled to practise in Great Britain.

That this fact is often overlooked is evidenced
by the Registrar’s announcement that during 1894
he erased the names of 246 persons whose where-
abouts was unknown to him. It is to be feared
that the condition of mind which leads so large a
number of persons to be so indifferent to their
legal status, has been fostered to some extent by
the gratuitous system of pharmaceutical registra-
tion. The Pharmaceutical Society exacts no fee
for placing a person’s name on the Register, nor is
any registered person mulcted in a single farthing
in respect of the heavy expense of keeping, printing,
and publishing the Registers year after year. A
not unnatural consequence is that registered per-
sons are apt to lightly value their registration
and to forget its significance.

We may be allowed, too, to say something of the
labour entailed in keeping the Register. Enquiry
of the Registrar elicits that during the past year
over 3000 alterations have been made in the official
Register, and that a large portion of the work was
necessitated by changes of address. Over 500 new
names were added, and almost as many were
erased on account of death or under section 10
of the Pharmacy Act. The latter operation
necessitated a preliminary issue of nearly 700
registered letters in March, and 500 in September,
besides the publication of several hundred names
in this Journal (see Pharm. Journ., November 17,
1894). Moreover, in order to realise as far as
possible the words of the Act, and to produce a
“correct Register,” every local and divisional
secretary of the Society in the Kingdom was
furnished with a copy, and was invited to point
to out the Registrar any inaccuracies he might
discover. If, therefore, the present edition is not
absolutely accurate it cannot be attributed to any
neglect on the part of the official charged with its
preparation and revision.

PROPRIETARY FOODS.

We have had frequent occasion to point out the
demoralising effects of the abuse of proprietary
medicines, and now have to notice a recent grave
indictment of proprietary foods. Dr. Barlow, in
the last “Bradshaw” Lecture delivered before the
Royal College of Physicians, spoke of infantile
scurvy in its relation to rickets, a subject that had
previously been brought into prominence by Dr.
Cheadle, whose work on the artificial feeding of
infants is well known. We are not in a position
to discuss the causes and effects of rickets, but it is
common knowledge that the crowds of children who
fill the out-patient rooms of the hospitals of large
towns are in a great proportion of cases suffering
from rickets or deformities of the limbs or of the
chest caused by this disease. But disease induced
by improper or insufficient food is by no means
confined to the poorer classes. Indeed, Dr. Bar-
low lays stress on the fact that the combination of
scurvy with rickets is of more common occurrence
among the children of the well-to-do than among
those of the poorer classes. This is attributed to
the fact that social duties may so tax the energy
and time of some mothers that the natural food,
and the only perfect food for infants—mother’s milk—is not available.

When from any reason the natural food is not to
be had, the usual substitute is cow’s milk diluted
with thin barley water. This is a dangerous food,
unless the utmost care is taken to boil the milk,
which must be obtained quite fresh at least twice
a day, and to sterilise all vessels by boiling water
each time they are used. Diluted cow’s milk is
less digestable than human milk, and does not
contain the nutrient ingredients (proteid, fat,
carbohydrates, and salts) in the proper proportion.
By the addition of raw meat-juice, cream, and
sugar, it may be brought up to the right nutritive
power, but to judge what modifications are
necessary in any case requires the greatest care on
the part of the experienced medical man, and we
are only concerned with the principles of feeding
in order that those who purchase artificial foods
without having obtained medical advice—and in
the poorer districts this is commonly the case—
may be cautioned. By the help of Dr. Cheadle’s
work we will pass in review some of the chief forms
of proprietary foods, and may state at once
that any of those which pretend to be a complete
food, and to require merely the addition of water,
is to be condemned as misleading, for, though it
may contain the necessary elements, they are so
altered by the mode of preparation that they are
likely to cause disease.

In the first place the commonest kind of prepara-
tion, namely, the farinaceous foods, may be noticed.
These are only to be used as additions to diluted
milk. Some, that consist chiefly of starch—like the
domestic arrowroot—may be condemned as indi-
gestable and almost useless. Foods prepared from
fine wheaten flour heated to a high temperature,
though more digestable, are of but little use, as
they are greatly deficient in proteins. Chapman’s
whole-meal flour contains much protein, but re-
quires prolonged boiling to break up the starch,
and cannot be used for very young infants, probably
on account of the irritating, though finely divided,
particles of the husk. Malted foods are prepared
by mixing malt meal with wheat meal, and warming
until part of, or all the starch is converted by the
diastase into dextrine, or grape sugar. Such foods
make a useful addition to diluted milk, but they
should never be used alone. Dr. Cheadle has
pointed out that the whole-meal food, when malted, can be used as an adjunct to diluted milk even for young infants. Malted foods with dried animal protein added are insufficient without the addition of fresh milk.

The second group of foods to be mentioned are the various forms of condensed milk. Many children are said to have done well on this alone, but, still following Dr. Chaddie, their deficiency in cream and their altered molecular constitution render them liable to cause rickets or even scurvy. The great excess of cane sugar in such preparations is a further obstacle, and the unsweetened forms are likely to be soured, and so are highly dangerous. But for a temporary diet, and especially on voyages, these preparations are of the utmost service. Another group consists of the meat preparations. Most of them—like beef-tea—are not foods but stimulants, and if used as an exclusive diet would lead to starvation. Meat peptones are highly nutritious, but are only required in cases of sickness, and so are to be given at the order of a medical man. Reference has already been made to raw meat-juice. It can only be a domestic preparation, as it must be absolutely fresh, and no artificial preparation can replace it. Lastly, mention must be made of pancretised and other pre-digested foods. What has been said above of meat peptones applies to them. If given for a long period they cause impairment of the functions of the digestive organs, and their employment should be regulated by medical advice. Thus it appears that not a single artificial or proprietary food is sufficient in itself. Many are useful as adjuncts to diluted milk, or in times of sickness.

THE LIQUEFACTION OF GASES.

In Nature for January 10, a claim for priority with respect to the liquefaction of gases is advanced by C. Olaszewski, of the University of Cracow, who states that he has been engaged since 1883—at first in conjunction with the late Professor Wóźbierowski, then alone and, later, associated with Professor Witkowski—in the examination of the so-called permanent gases at very low temperatures, and that all except hydrogen were liquefied in quantity by him. In addition to this, he apparently claims to have been the first to determine the critical and boiling points of these bodies, and to solidify and determine the freezing points of nitrogen, carbon monoxide, nitric oxide, and methane. Further, he charges Professor Dewar with repeating his experiments and copying his apparatus without due acknowledgment, thus gaining reputation at his expense, and with having been credited by the British public with priority in the liquefaction of oxygen and other gases. Professor Dewar, in reply, points out what should sufficiently obvious to everyone acquainted with the subject, namely that, considering the Davy Medal was awarded by the Royal Society in 1878, to Callender and Proctor for their achievements of the liquefaction of the gases in question, it is hardly likely he could put forward in England any claim for such a result. The assertion that the apparatus used at the Royal Institution was copied, is refuted also, as well as the statement that proper acknowledgment had not been made of the labours of foreign workers.

LONDON UNIVERSITY.

On Tuesday last Lord Rosebery received two deputations on the subject of a teaching university for London. The first, introduced by Professor Huxley, supported the recommendations of the Gresham Commission; but that introduced by Mr. Fletcher Moultin protested against the proposed change, which, it was alleged, would contract the scope and lower the standard of the competition for degrees and honours. Lord Rosebery acknowledged the strength of the arguments on both sides, but inclined to the views of Mr. Huxley, and later in the day the Convocation of London University practically confirmed his choice by adopting the report of the Gresham Commission and rejecting hostile amendments. The Daily News points out that a Statutory Commission will have to be appointed by Parliament before the union can be carried out, and as a single member of Parliament might make it very difficult to pass the Bill, the matter is by no means settled yet. The University of London has hitherto confined itself to examining candidates and giving them academic certificates of their capacity. It has not taught anyone, and has never asked, where candidates came from. Professor Silvanus Thompson makes an unfortunate reference to “cobblers,” likely to damage the cause in which he was speaking. The University has justly boasted that it regarded only knowledge, and was no respecter of persons. But the drift of public opinion is in favour of combining instruction with examination.

THE TRUSTS OF THE ROYAL SOCIETY.

One of the immediate results of the recent discussion in the Times, concerning the Rumford medals, has been the reading of a paper on "The Trusts of the Royal Society," by Sir John Evans, at the meeting of the Society on January 17. A brief report of the paper, which was virtually a catalogue of the various trust funds vested in the Royal Society—seventeen in number—appeared in the Daily News. The seventeen funds have vastly different incomes and objects. Of these the richest is the Scientific Relief Fund, which has at present an income of about £970, and is devoted to "the relief of those who have conferred on the knowledge of the sciences, or their families, any services, who, from any cause, are in circumstances requiring assistance." The Rumford Fund, amounting to £2,330, provides that the interest of this money is to be given once every two years as a premium to the author of the most important discovery or useful improvement which shall be made or published by printing or in any way made known to the public in any part of Europe during the preceding two years, on heat or on light. The list is too long to set forth at length, but the oldest and newest funds may be mentioned. The oldest is the Croonian Lecture Fund, which dates from as far back as 1660, and provides for the support of a lecture and illustrated experiment for the advancement of natural knowledge on local motion, or such subject as may be deemed useful by the President for the time being; the newest is the Buchanan Medal Fund, which provides for a medal to be awarded every five or seven years for distinguished service in hygienic science or practice in the direction either of research or professional, administrative, or constructive work.
Proceedings of Societies in London.

CHEMICAL SOCIETY.

A meeting was held on Thursday, January 17, 1895, the President, Dr. Armstrong, F.R.S., in the chair.

The following papers were read:

OCTACETYL MALTOSE.

BY A. R. LING AND J. L. BAKER.

The physical constants of this substance obtained in a crystalline condition were re-determined and found to differ slightly from those previously recorded by Hersfeld, particularly with regard to the rotatory power and crystalline form. The figures obtained by the different observers were:

\[ [\alpha]_D = +81^\circ 8 \text{ (Hersfeld)} \]
\[ [\alpha]_D = +61^\circ 22 \text{ (Ling and Baker)} \]

Since this compound is used in the identification of maltose, this correction is important.

THE ACTION OF DIASTASE ON STARCH.

BY A. R. LING AND J. L. BAKER.

The authors have examined the hydrolytic products of starch when acted on by diastase. The diastase was obtained from different sources, and prepared by different methods. The authors confirmed the previous results recorded by Brown & Morris, since they obtained maltodextrin, the physical constants of which were determined and found to agree with those given by Brown and Morris. "Isomaltose," another product of the hydrolysis of starch, was also isolated, and the osazone on examination possessed the same melting point as that recorded by Lintner.† The isomaltose was purified by crystallisation and precipitation from methyl alcohol solution by absolute alcohol. The isomaltose thus obtained agreed in these respects with that obtained by Lintner, but on treatment with sodium acetate and acetic oxide a mixture was obtained from which octacetyl-maltose was separated and identified. The isomaltoozone was also proved to be a mixture, since maltoozone was separated and identified. Further experiments on the action of diastase and determination of its reducing power showed that isomaltose is not a homogeneous substance, but a mixture of maltose with probably two other substances. One of these was separated, and from examination of the osazone is probably a new sugar—\( C_{12}H_{22}O_{14} \)—for which the name amylotriose is proposed. The other substance present in isomaltose appeared to be a dextrin which, however, was not identified.

Mr. H. Brown, F.R.S., stated that experiments in progress in his laboratory confirmed the conclusions recorded above as to the non-homogeneity of isomaltose so far as that it was not a pure substance nor an isomer of maltose.

Dr. Kipping suggested that a better name for the new sugar would be triamylose.

‡ Zeit. Brauwesen, XV., 145.

NOTE ON DERIVATIVES OF CAMPHOR.

BY M. O. FORSTER.

Of the two dibromocamphor previously described melting at 61° and 114° respectively, only the beta- or higher melting substance yield a nitro-derivative. Both, however, on reduction, yield first monobromocamphor and then camphor. When \( \alpha \)-dibromocamphor is treated with fuming nitric acid, heat is evolved and an oil is obtained which, when steam distilled, yields crystals which may be easily purified by crystallisation from alcohol. This substance has the formula \( C_{10}H_{12}Br_2O_4 \), is an inert substance, not reacting with phenylhydrazine or hydroxylamine, and yields on reduction with zinc dust a substance of the formula \( C_{10}H_{12}BrO_3 \). This latter substance is phenolic in character and reacts neither with phenylhydrazine, hydroxylamine or acetyl chloride, but with bromine yields \( \alpha \)-dibromocamphor. When acted on by a mixture of nitric and acetic acids, carbonic oxide is split off and a substance formed of the formula \( C_{10}H_{13}BrO_3NO \). The reduction products of this compound are being examined.

THE ACID SULPHATE OF HYDROXYLAMINE.

BY DR. DIVES.

Several hydrochlorides of hydroxylamine are known but hitherto the acid sulphate has not been prepared. When an aqueous solution of the acid sulphate is treated with alcohol, crystals of the normal sulphate are obtained. The acid sulphate may be prepared as follows—the equivalent quantity of sulphuric acid is added to solid hydroxylamine hydrochloride, and the mixture then placed in a large dish and heated on a water bath, when the hydrogen chloride is driven off. The mass is then allowed to cool in a dry atmosphere, when long crystals separate, which are, however, very deliquescent. The identity of the substance was proved by titration of the acid by normal alkali, methyl orange being used as an indicator.

THE HYPOPHOSPHITES OF MERCURY AND BISMUTH.

BY S. HADA.

These hypophosphites have not previously been prepared. When solutions of mercuric nitrate and sodium hypophosphate are mixed, mercurocyan hypophosphate is formed and separated as a double salt, which is perfectly stable and crystalline, and has the formula \( HgHPO_4 \cdot HgNO_3 \cdot H_2O \). On heating at 100° it explodes, and with hydrogen chloride yields calomel and then mercury. Bismuth hypophosphate is precipitated on mixing solutions of bismuth nitrate (free from acid) and calcium hypophosphate. The precipitate is a white crystalline powder which must be at once separated by filtration from the mother liquor, otherwise decom position takes place. The salt is decomposed by water yielding phosphine, \( PH_3 \), and other products, and on heating the salt decomposes according to the following equation:

\[ 3 \text{Bi}(H_3PO_4)_2 = 2 \text{Bi} + \text{Bi}(PO_4)_3 + 6P + 9H_2O, \]

and yields metallic bismuth, phosphorus, bismuth phosphate and water.
ROYAL INSTITUTION.

The lecture theatre of the Royal Institution was filled to its utmost capacity on the 18th inst., when Professor Dewar, LL.D., F.R.S., discoursed on "Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air," before an audience which included the Marquis of Lorne, Lord Playfair, Lord Rayleigh, Sir Frederick Abel, Professor Crookes, and many other eminent scientists. The lecture was, to a great extent, a popular version of that given before the Chemical Society on June 28, 1894 (see Pharm. Jour., July 7, 1894).

At the outset a few experiments were performed to illustrate the modification of the molecular elastic properties of bodies caused by exposure to the temperature of boiling liquid air. By this it was demonstrated that not only the breaking, but also the torsional, strain was increased to a great extent. Thus a metal spiral which at the normal temperature was incapable of supporting a certain weight, after being immersed in liquid air, and thus exposed to a temperature of \(-190^\circ\) C., readily sustained it, but gradually returned to its former molecular condition after exposure to the atmosphere temperature. The effect of immersing various substances in liquid oxygen was next shown, in some cases chemical action taking place, but often the reverse. When ignited sulphur was used the reaction was very striking. At first it continued to burn, but its combustible tendency was gradually overcome, leaving a residue of solid sulphurous acid. After briefly alluding to the work of other scientists on phosphorescence—especially to the researches of the Becquerels, father and son, from about the year 1840—Professor Dewar performed several experiments illustrative of the effects of heat and cold upon phosphorescence. It was thus generally shown that phosphorescence induced in stimulated bodies at \(-180^\circ\) C. was greatly excited by subsequent rise of temperature; on the other hand, a body which was normally phosphorescent, on being cooled to \(-80^\circ\), had its phosphorescence temporarily discharged, but it was restored on heating. With regard to the parts of the spectrum which are most active in stimulating bodies, and hence in Inducing phosphorescence, the ultra-violet rays are found to be those which produce the effects, the phenomenon consisting of the absorption of the ultra-violet rays and emission of those light rays which come within the range of our vision; and it was also shown that the luminous and heat rays are able to disipate the luminosity of a phosphorescent body in those parts upon which they have fallen. The terms fluorescence and phosphorescence were then compared, the distinction made being one of degree rather than of kind, since, as much as "phosphorescence is a species of fluorescence, which lasts for a much longer time after the excitation has ceased."

Attention having been drawn to the construction and use of the phosphroscope, an instrument which measures the period during which a stimulated body exhibits phosphorescence, the effects of cooling to \(-180^\circ\), upon a variety of substances which at the normal temperature were very faintly, or more often not at all, phosphorescent were then shown. In each case the body glowed brightly, after being cooled by plunging into boiling liquid air, and then stimulated. Amongst the substances shown were cotton-wool, horn, leather, celluloid, feathers, silk, a flower and an egg-shell; and the experiments were variously modified in order to show that phosphorescence was only exhibited at the part where the cooling had taken place, and that stimulation by exposure to an electric beam of light was in all cases essential. The fact that oxygen when cooled is phosphorescent was also demonstrated. Considerable skill was necessary in the manipulation, as, not only in many cases was the phenomenon only visible for a few seconds, but also the intense cold in many cases made the substance so brittle that its removal from the jar of liquid air was almost impossible. Passing on to the examination of organic compounds of definite chemical composition, the three types shown were acetic acid, quinine sulphate, and acetamide. Here the action of the glass containing the substances, in stopping to a certain extent the stimulating rays was strikingly shown, the result being phosphorescence which was brilliant in the extreme. The ketones as a group were referred to as a class of organic compounds which exhibit the phenomenon remarkably well. Lastly, the platino-cyanides of lithium and ammonium were shown, giving a brilliant light. Speaking generally it appears that in substances of definite chemical composition which are volatile and can be distilled and crystallised we have conditions which are favourable for phosphorescence.

When dealing with photographic action at low temperature, it was clearly shown that it could be carried on at a temperature of \(-190^\circ\), although reduced in power to the extent of 80 per cent. For this purpose sensitised paper was sponged in one part with liquid air, and then exposed to a bright light. The contrast between the part so cooled, where apparently no change had taken place, and the reduction on the remainder of the paper was very evident. The question thus arose as to whether photographic action would cease entirely if we had a temperature of \(-274^\circ\), that of absolute zero. This, of course, can not be settled until the variations in photographic sensibility at various temperatures have been determined by experiment and indicated by a curve. In conclusion Professor Dewar referred to the possibilities of the nature of this phenomenon of phosphorescence. As the matter stands it is pure speculation. If chemical, it is certainly the only kind of chemical action at low temperatures. If physical it may be regarded as the equivalent of some mere physical change which might be termed latent vibration, but it may at least be stated that photographic action and phosphorescence are intimately connected, and thus fluorescence, phosphorescence, and photographic action blend one into another.

In his second lecture on the internal framework of plants and animals, on January 29, Professor Stewart...
dealt first with the principal stiffening or supporting element in the higher flowering plants, namely the wood, of which he followed the development and explained the structure. It was shown that in the winter bud of the ash tree, for example, there are contained the rudimentary leaves ready for rapid elongation in the spring; the fibro-vascular bundles from these, the Professor explained, passed into the stem and united with the bundles from lateral branches, as well as from previous leaves, to form a ring. The further growth of this ring was effected by the activity of the cambium, which produced wood, with vessels and fibres, on the one side, and phloem, with sieve tubes and bast fibres, on the other. The lecturer next described the formation, in the vessels of the wood thus produced, of a resin or gum resin, usually dark in colour, which both blocked up their cavities and passed by infiltration into the walls of neighbouring cells, rendering them impervious to aqueous fluids; the wood thus affected was called duramen, or heartwood, and its function was purely mechanical.

Professor Stewart next considered the remarkable branched cells found in the leaves of various species of Camelina and Aneura, and illustrated his remarks by a description of those present in the leaf of Welwitsea, pointing out the purely mechanical nature of the function they discharged, and showing the manner in which the walls of some were further strengthened by a deposition of crystals of calcium oxalate.

With these remarks the lecturer concluded his account of the internal framework of plants, and passed on to consider that of animals. From the lower forms of Protozoa he selected the sun animalcule as an illustration, and drew particular attention to the protoplasmic threads which assisted the animalcule to procure food, and possibly served for purposes of locomotion; in these threads a finer supporting filament could be seen. In Acanthocoea a central mass of protoplasm was enclosed in a perforated organic membrane, and surrounded by vacuolated protoplasm; the protoplasmic threads in this case were enclosed in delicate tubes composed of acanthin; in other allied forms siles, the supporting material, was siliceous in its nature.

This lecture, like the previous one, was illustrated by sketches on the blackboard, and by preparations of the bud of the ash, Welwitsea, sun animalcule, etc., exhibited under the microscope.

CHEMISTS' ASSISTANTS' ASSOCIATION.

There was but a scanty attendance at 103, Great Russell-street, on the 17th inst., which was variously attributed to the fact of the Chemists' Ball having been held the night before, and to the weather. Mr. R. H. Jones, the President, occupied the chair, and after the minutes of the previous meeting had been read and confirmed, Messrs. Horatio N. Bolton, A. G. Phillips, and J. E. Saul were elected patrons of the Association. Mr. J. S. Ward then read his paper entitled "Sophistication a Century ago." In an interesting sketch of the methods of adulteration practised, some amusing quotations were given from Smollett's works, to show the nature of the impurities met with at that time amongst the apothecaries' stocks, and allusion was made to the antagonism which afterwards existed between the apothecaries of the old school and the medical profession proper, just as the pharmacist of to-day is engaged in strife with the stores. Writing about the year 1783, Dr. James refers to the sophistication of various preparations. Thus elaterium is described as the "expressed juice of the spruce larich thickened with mucilage of gum traganth," whilst balsam of Peru was nothing more than liquid storax. Aloes was made up of a mixture of gamboge and hepatic aloes. At that time it may be noted that the price of Barbadoes aloes was about 3s. 6d. per lb., whilst Soocotrine aloes was a shilling less. The composition of some of these drugs certainly reflected credit upon the inventive faculties of the sophisticators. Thus we find Chian turpentine composed of olive oil, yellow resin, and Canada balsam; syrup of violets of orris root, sugar, and water, coloured with indigo; oil of laurel of lard, palm oil, green ointment, and rape oil. Mr. Ward had taken the trouble to prepare adulterated specimens of oil of aniseed, balsam of Peru, Chian turpentine, aloes, and dragon's blood, according to old formulae, so as to give some evidence of the nature of the products.

With regard to the means by which these admixtures were detected, physical tests were, of course, mostly relied on. Chaff, hair, bran, and sawdust were met with in liquid storax; balsam of Peru when adulterated was of very thick consistency, and with difficulty soluble in spirit; whilst musk was a conglomeration of skin, blood, and various refuse matter. The best variety of civet came from America, whilst the sagapenum had a different appearance to that now met with in commerce. The use of drugs and chemicals in the manufacture of beverages was noticed. Thus alum was used in wine-making, and oak sawdust for red wines; gypsum and sugar of lead for "cleaning," and cayenne pepper to impart pungency, with quassia as a substitute for hope.

In the discussion which followed the opinion was generally expressed that the sophisticated specimens of dragon's blood and Peru balsam would pass muster even at the present day.

The thanks of the meeting were, on the motion of Mr. J. C. Strother, seconded by Mr. E. W. Hill, accorded to Mr. Ward.

ROYAL MICROSCOPICAL SOCIETY.

The annual meeting of this Society was held at 29, Hanover Square, W., on January 16. The President, A. D. Michael, Esq., F.L.S., was in the chair. After the report of the Council for the past year, and the treasurer's statement of accounts had been read and adopted, the President announced that the following were elected as officers and Council for the ensuing year:—President, A. D. Michael, Esq., F.L.S.; Vice- Presidents, Professor L. S. Beale, F.R.S., Dr. R. G. Hobbs, E. M. Nelson, Esq., T. H. Powell, Esq.; Treasurer, W. T. Suffolk, Esq.; Secretaries, Professor F. Jeffrey Ball, Dr. W. H. Dalling, F.R.S.; Ordinary Members of Council, T. D. Aldous, Esq., C. Beck, Esq., A. W. Bennett, Esq., Dr. R. Braithwaite, Rev. E. Carr, Frank Crisp, Esq., E. Dadswell, Esq., G. C. Karop, Esq.,
The President then delivered an address, the subject of which was, "The History of the Royal Microscopical Society." He said that if any of his hearers would leave that West-end abode of science and journey eastward to Tower Hill, and thence by Sparrow Corner along Royal Mint Street, he would find himself in Cable Street, St. George's in the East, not a very quiet or a very clean locality; turning down Shorter Street he would emerge opposite a space of green, where once stood the Danish church with its Royal closet reserved for the use of the King of Denmark when visiting this country. The space is surrounded by houses which have seen better days, and amongst them, between a pickle-factory and a brewery, stands a rather dilapidated erection which is 50, Wellclose Square; there, in 1839, lived Edwin J. Quekett, Professor of Botany at the London Hospital; and there, on September 3 of that year, seventeen gentlemen assembled "to take into consideration the propriety of forming a society for the promotion of microscopic investigation, and for the introduction and improvement of the microscope as a scientific instrument." Among the seventeen were N. B. Ward—the inventor of the Wardian case, which is not only an ornament to town houses, but was the means of introducing the tea-plant into Assam and the cinchonas into India—who became treasurer of the Society; Bowerbank Lister, who has been called the creator of the modern microscope; Dr. Farre; Dr. George Jackson; the Rev. J. B. Reade; and the enterprising and scientific nurseryman, George Loddiges. Most of these subsequently became presidents of the Society. A public meeting was held on December 20, 1839, at the rooms of the Horticultural Society, then at 21, Regent Street, when the "Microscopical Society of London" was formally started. Professor Richard Owen (not Sir Richard at that time) took the chair, and became the first President; and shortly after the famous John Quekett became secretary, an office which he held almost to his death.

At this moment Schieden in Germany was commenting upon the paucity of British microscopic research, and attributing it to the want of efficient instruments, not knowing that a society was then forming which was to raise British microscopes to probably the first position in the world. The President then traced the history of the Society through the presidents of Dr. Lindley, the botanist, Professor Thomas Bell, the zoologist, Dr. Bowerbank, Dr. George Busk, Dr. Carpenter, Dr. Lankester, Professor W. Kitchen Parker, all deceased; and of others equally famous who are still living; and showed how, under its influence and by its assistance, the vast improvements in the microscope, and the enormous extension of its use, had gradually arisen. He also described its connection with the origin of the 'Quarterly Journal of Microscopical Science,' the 'Monthly Microscopical Journal,' and other publications, besides its own present widely circulated journal with its exhaustive summary of microscopic and biological work. He related how on John Quekett's death certain members of the Society subscribed to purchase for the Society's collection a curious microscope which Quekett possessed, and which had been made by the celebrated Benjamin Martin about 1770, probably for George III., and how they extended their subscription so as to provide a medal to be called "the Quekett medal," to be given from time to time to eminent microscopists; and how, difficulties having arisen, it happened that the only Quekett medal ever awarded was given to Sir John Lubbock.

Finally the President considered the future of the microscope and the prospects of further improvements. He said that many people were of opinion that the instrument is now perfect, and that consequently the most important raisons d'etre of the Society was over; he by no means agreed in that view; he believed that there was as much scope for progress in the future as there had been in the past. It was not by any means the first time that this idea had been put forward. In 1839, Dr. Goring, then a great authority on the subject, wrote in one of his published works, "Microscopes are now placed completely on a level with telescopes, and like them, must remain stationary in their construction." In 1830, less than a year after, appeared Lister's epoch-making paper, "On the Improvement of Achromatic Compound Microscopes," and we have been improving ever since.

Mr. H. Virtue Tobbs proposed a vote of thanks to the President for his address, this having been seconded by Professor Bell, was carried unanimously.

UNIVERSITY COLLEGE (LONDON) CHEMICAL AND PHYSICAL SOCIETY.

At the meeting held on January 16, a paper was read on—

OPium.

BY ROBERT D. LITTLEFIELD.

It dealt with the history, cultivation, and constitution of the drug. In the course of his remarks the lecturer referred to ancient records of opium, mentioning Sorbinius Largus, A.D. 40, who gave an account of opium preparation, and Dioscorides, A.D. 70, who recorded the fact that the juice of the whole opium-bearing plant is less active than that of the capsule alone. Later, Pliney, in addition to noting its preparation, describes its medicinal use. In ancient Latin records reference is frequently made to Locarnioppavocors, indicating that at that time even opium was looked upon as a valuable drug. Concerning the cultivation, an explanation of the formation of the latex in the plant was given, and the general manner in which the capsule was enclosed, the juice scraped off, and collected.

The plant as cultivated in Asia Minor usually has white or purple flowers, and blooms in May to July according to the elevation of the land. A naturally rich and moist soil is required, and a drought, frost, or locust pest may wreck a good healthy plantation. The opium specimens shown, kindly lent by Messrs. Hearon, Squire, and Francis, were then explained, the various characteristics being shown distinguishing the Asia Minor, Turkish, Indian and Egyptian varieties. The peculiar narcotic bitter smell and taste were pointed out, and concerning the composition, the
lecturer said that roughly speaking half of a sample of opium consisted of albumen, fruit, juice, gum, fragments of leaves and rubbish, and the remainder contained the alkaloids, sugar, and according to Hesse, some wax. The acids present are sulphuric, phosphoric, and the one peculiar to the poppy, meconic acid.

The inorganic constituents are potassium, magnesiam and calcium oxides. The list of alkaloids in opium itself found, though very great, (some twenty or so,) was possibly not yet complete. Some were entirely absent from samples of the gum, and if present were only there in minute traces. Morphine and its derivative apomorphine (discovered by Matthiessen and Wright), codeine, and narcotine were the principal ones. The method of assaying the morphine in opium as given in the B.P. was explained.

The morphine existing in the opium as sulphate and meconate is soluble in excess of calcium hydrate. This solution is treated with S.V.R. and ether in certain proportions, and the addition of ammonium chloride causes the precipitation of the morphine, which is insoluble in the S.V.R. and ether mixture, whereas other organic substances which the NHCl throws out are soluble; so that morphine was obtained in a practically pure state, and can be weighed after the necessary drying. After reference to apomorphine, some tests for morphine were shown, and emphasis was laid on the reaction of neutral ferric chloride on an aqueous solution of opium, the beautiful red-coloured solution produced (that of meconate of iron) being unaffected by mercuric chloride. This being an almost conclusive test for meconic acid, inferred the presence of opium in the solution tested.

In a discussion which ensued, Dr. Norman Collie referred to the ferric chloride test. He stated that some of the aceto-acetyl derivatives gave this colour exactly, and that this fact very possibly indicated the presence of this group in the formula of meconic acid. Mr. Das also mentioned the effect and use of opium smoking and eating in Northern India. He remarked that the belief there was that the use of the drug was beneficial in preventing the severity of malarial attacks and also the intensity of poisonous snake bites.

After the usual vote of thanks had been acorded to the donors to the library and museum and to the authors of papers during the late session, also to the officers and Council for their services, the President delivered the following:

**INAUGURAL ADDRESS.**

It is my duty on the occasion of the opening of this session, to address some observations to the members on such subjects as appear to me to call for comment. Seeing that we inaugurate a session which shows this Association to have existed for nearly half a century, one is tempted to look back upon the work done by the Association and to the honoured names long connected with it. But though a creditable history has its usefulness in stimulating effort and promoting aspirations, in this utilitarian age we estimate the value of an institution from its performances at the present time and its promise for the near future rather than its past.

The aims of the Association amply justify its existence, and that those aims are not altogether missed is manifested by the regular attendance at the meetings of a fair number of active co-operators. If the Association falls short of its capabilities, the responsibility rests mainly upon those who have withheld their assistance. The first of the rules of the Association says it "shall have for its objects the advancement of chemistry and pharmacy, and the furtherance of the trade interests of members engaged in the same." It will be readily admitted that pharmacy and pharmacy receive a proper amount of attention, and that the time spent upon those subjects is profitably employed. The occasional evenings spent at these meetings, looked at in a purely commercial light, have always appeared to me an excellent investment. The miscellaneous information that is circulated has a value in pounds, shillings and pence, which it would be unwise to underrate, and which few of us can afford to despise. We have also opportunities for making acquaintance and conversing with men whose interests and sympathies are in line with our own. It is by such means that unity and consolidation are promoted, and that ways and means are discovered for defending our interests when they are threatened.

Among trade matters which have recently engaged attention, I think the revision of the 'Liverpool Chemists' Retail Price List' deserves mention. A very great deal of time and thought have been devoted to it, many changes and additions have been made; and in every case where an alteration is recommended, either in the direction of higher or lower price, it has not been done without sound reasons. It is a book which ought to be in the hands of every chemist in this district, and not in this district only.

In this matter of prices, I am disposed to think that chemists too often stand in their own light by quoting for small quantities when price is asked. The grocer or store-keeper sells his carbonate of soda by the pound or half-pound, the chemist more frequently in one or two ounce packages, and as the price for the smaller quantity must be proportionately higher, the
two prices are sharply contrasted, to the prejudice of the chemist as a retailer. The system recommended in the Liverpool Price List is an admirable one, and should be generally followed; that is, when no pound price is mentioned, of charging the same number of shillings per pound as pence per ounce. We have got into a groove of small transactions which is not good for us; the public would esteem us more highly if they spent more money with us, and we ourselves would profit in more than the immediate gain by effecting the larger, rather than the smaller sale. The following words, taken from the Pharmaceutical Journal of December 1, are worth repeating:—"The pharmacists' charges should be classed under three distinct heads: The highest remuneration for purely professional work, such as dispensing and analysis; the next for semi-professional work, such as the supply of drugs and chemicals, which he personally guarantees; and the lowest for purely trading operations, such as are involved in the sale of articles which he simply hands over in the same condition as he receives them."

I submit that the attitude respecting prices which all engaged in pharmacy should take is correctly indicated. It is certain that without a fair average remuneration we cannot continue to prosecute our business as a source of livelihood.

When the quiet seasons of the year are with us we incline to the opinion that we can only maintain our position by reducing prices. This is in some cases done, the lead is followed by the nearest competitor, who perhaps goes one better (or worse); he, again, is followed by his neighbour on the other side, and so the thing spreads, the end being that profits are reduced without any appreciable increase of business. I do not, on the other hand, recommend excessively high charges, such as were sometimes made years ago, and would be inconsistent with the present conditions of business. But there is a middle ground.

In all large towns, as well as drug-selling grocers and drapers, there can be found a few successful, or apparently successful, cutting men who are on the Register, and who stand out with some prominence, due to their cheap-jack methods of advertising; but there are others, and many of them, who have adopted this system of business and have failed to succeed. Fortunately there are also many successful ones who follow what we are accustomed to regard as higher and more legitimate methods of business. In the great majority of cases I believe the success to be that of the man, not of the system, and that the one who succeeds as a cutter would have been equally successful on other lines.

As a body we appear to be getting crowded out, pushed into corners, and it must be that in the struggle we are lacking in some essentials. I have long had a strong conviction that our long hours of business are responsible for many of our deficiencies. We have amongst us men of intelligence, perhaps above the average, the finer side of whose character is cultivated and developed, but who in their business are unable to earn more than will furnish a bare subsistence for themselves and their families. The present conditions require that our attention must be fixed upon business for thirteen, fourteen, and even fifteen hours out of the twenty-four. If we incline towards scientific studies, we find that with frequent interruptions consecutive thought is impossible. - We must do our reading as we take our meals, in snatches; we must not discuss controversial subjects with our patrons; we are not free to mix with the world as others do even in sociable intercourse with friends. In other words we miss the sharpening influence of freer contact with men of the world. These conditions cannot but have a deteriorating influence upon us as individuals and as business men. The looker-on, who is said to see the most of the game, would say that these conditions could not fail to give rise to a non-development of character, in consequence of which a man so placed would be unable to do justice to his natural abilities; that the individuality which is the source of success would be restricted.

Business capital consists not only in stock, fixtures, and bank balance, but to a very large extent in the man himself; in the intelligent thought and study by which he keeps himself informed of recent knowledge in connection with his business, and in his knowledge of the world and of human nature. It is rarely that this capital can be used to the best advantage where the mind is confined in one groove for thirteen hours in each day.

I think the principle is now very generally accepted that the value of output is increased by diminishing the hours of labour—within reasonable limits, of course—and it would be worth the while of chemists to give this matter their serious consideration. We suffer under a tyranny by which we are injured in health of mind and body, and in domestic comfort; we concur in an evil which has no compensations. As individuals we are the victims; collectively we are the oppressors.

What I have said applies with equal force to Sunday trading; it is deplorable that an educated and highly intelligent man should be called upon to supply confectionery and articles for the table such as mustard and vinegar on the one day of the week when he should be free to spend some portion of his time in leisurely rambles in country lanes, or in the restful contemplation of such beauties as nature has provided his locality with.

I do not think it necessary to deal in advance with the argument that medicines are required on Sundays as on other days, and late as well as early; I know how much and how little force there is in that argument.

It is not a voluntary nine o'clock closing hour I am now advocating. To use a historic phrase, "I would not take my coat off" for that. This Association has on former occasions endeavoured to organise a voluntary early closing movement, and we all know how short a time the arrangement lasted. Experience has shown voluntary agreement to be futile: nothing but the compulsory powers of an Act of Parliament can effectively deal with this evil. The Bill which Sir John Lubbock proposes to bring before the House of Commons in the next session is one which, in my
opinion, we ought to do something to assist. The Bill could not be in better hands. Sir John Lubbock is a humanitarian and man of science more than a politician, and perhaps no man in either House of Parliament would have greater influence upon a question of this kind. In addition to Sir John Lubbock, the movement is receiving the active support of Mr. Chamberlain, who includes it in his unauthorised programme, and, however opinions may differ respecting Mr. Chamberlain’s politics, there can be no doubt that his advocacy of the measure will have great weight in some quarters. As well as the two I have named the Bill is backed by seven other members. It will be remembered that in the last session of parliament a resolution in favour of compulsory early closing of shops received the support of a majority of the members present, and though it may be said that it was a narrow division, it is certain that the question is now “within the range of practical politics,” and it remains for those interested to make their wishes known. If the chemists of Liverpool are in favour of this measure, and desire to strengthen the hands of the leaders of the movement either by resolution or petition, I am sure this Association will lend its assistance as it has always done when the interests of registered chemists in this locality are concerned.

I know there are many members of this Association and many others who are not members, but whose assistance at these meetings would be welcome, to whom my remarks upon the subject of early closing would have no application; but I am sure they will not regard the time spent upon a subject of such commanding importance as wasted, and that they would be more than willing to help forward anything that would add to the happiness of their brother chemists less fortunately situated. As a class, we miss the varieties and amusements of life and the thousand and one things that are factors in the formation of character and make life worth living. Let us hope for a fairer prospect in the future, and, at the same time, let us remember that we have no right to look to others to accomplish for us that which we have neglected even to assist in.

Education and examination continue to receive a considerable amount of attention. In reference to the “First” examination of the Pharmaceutical Society, I would support those who advocate a higher standard. The standard that is recognised by the medical faculty is quite low enough. Without the basis of a good earlier education, many of the terms used in botany, chemistry, and physics are meaningless sounds, and the committing them to memory is of the nature of “ cram.” I also support the curriculum scheme of the Pharmaceutical Society. Of the schools of pharmacy of which I have any knowledge, my opinion is that they do what they profess faithfully and well, and that tuition is not merely just as much as is necessary for the student to pass an examination. If the student will give himself sufficient time, he will emerge with a sound and lasting knowledge of his subjects; but it is impossible that a large amount of detailed knowledge acquired under a few months’ instruction can take a permanent abiding place.

We learn that the Council of the Pharmaceutical Society is considering whether or not an amended Pharmacy Act should be attempted. It is not worth while repeating any of the arguments from our point of view against unqualified limited company pharmacy, nor perhaps is it necessary to urge upon the committee of the Council the importance of that question. In the face of such activity and wise discrimination as have been displayed by the Council of late years, I have confidence that they will neither “rush in where wise men fear to tread,” nor hold back from an attempt for fear of failure if a reasonable prospect of success offers.

If the President will tell us in plain words that by relinquishing what is called the “Widows’ Clause” he believes we would be in a position to effectually deal with the store question, I think he might count upon a large number of new entries to the Society. For my part, I am not at all sure that the clause is an unmixed good. Most of us know of widows who have carried on businesses with some success; but how many are there who, having tried it, have come to grief? And the circumstances of competition and the character of the business combine to make that practice more difficult and unprofitable each year.

In conclusion, gentlemen, it is not necessary for me to say that in choosing subjects for remark I have made no ambitious selections. There are many other opportunities for discussing scientific and technical subjects; and pharmaceutical progress is ably reviewed and chronicled in our trade journals. The topics I have dealt with are amongst the little things which combine to constitute an important whole. I have spoken of things which are as familiar to all here as to myself, and of some things in which you may have but a passing interest, and yet which are sapping the energies and injuriously affecting the well-being of some thousands of our fellow-chemists throughout the country. But it is only by calling attention to and inviting discussion upon these subjects that grievances eventually come to be redressed or bubbles are burst.

Mr. A. C. Abraham proposed a vote of thanks to the President for his interesting and practical address. This was seconded by Mr. J. J. Smith and supported by Messrs. Parkinson, Wardleworth, and Cowley. The President then replied, and the meeting terminated.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

A meeting of the above was held at the Society’s Room, 18, St. Edward’s Passage, on January 18, Alderman Deck, President, being in the chair, and a large number of members present.

Mr. Ernest S. Pock, gave a lecture on WEBER ANALYSIS.

He commenced by quoting the various sources of water supply, and drew a diagram of the section of a well he had seen in a country village, showing its close proximity to sources of sewage contamination.
He explained the care requisite for the collection of a fair sample for analysis in properly prepared bottles, and showed how the quantity of total solids was arrived at, determining the amount of chloride present by means of standard solution of silver nitrate.

Then followed the free and albuminoid ammonia estimated by the Nessler test. The presence of nitrates was detected, and the hardness of water and microscopical examination were touched upon.

The experiments were successfully carried out with specially arranged apparatus kindly lent by Mr. C. J. Heycock, M.A., King's College. After considerable discussion a hearty vote of thanks was proposed by the President, seconded by Mr. A. Ivatt, M.A., supported by Mr. A. S. Campkin, J.F., and carried by acclamation.

**MANCHESTER PHARMACEUTICAL ASSOCIATION.**

At the meeting of this Association on January 16, Mr. J. Rymer Young presided, and a paper was read on:

**CELL FORMATION AND CELL CONTENTS.**

**BY CHARLES TURNER.**

The author dealt with the nature and occurrence of "pyrenoids" and discussed their use in the economy of the plant. They were described as spherical or lenticular bodies occurring in certain Algae, especially in the Conjugate, Spirogyra being given as an example. They are imbedded in the chlorophyll band and appear to be in intimate connection with the nucleus by bands of protoplasm, while they are usually surrounded by a number of small starch granules, and their outer layer stains purplish with iodine. These facts lead to the idea that they are connected with the chlorophyll and nucleus in the elaboration of starch. A lucid description was then given of karyokinesis or the mitotic or indirect division of the nucleus in cell formation, and attention drawn to the different parts of the cell connected with this change.

By means of lantern slides the centroplastere were shown, first in their original position, close together just outside the nucleus, then in the position they take up when division is about to occur, on opposite sides of the nucleus and connected by means of kinoplasmic threads. The chromosomes forming the nuclear disc were shown, as well as their division, the method of which was explained, and finally the gradual formation of a layer of granules of cellulose in the equator of the cell, which coalescing, formed the new cell wall.

The cell contents were treated in a most comprehensive and instructive manner, and by means of a selection of slides Mr. Turner succeeded in making clear to his audience many difficult points in the anatomy of the plant. The contents of the living cell were described, the parts played by the formative and nutritive cytoplasm explained, and the plastids were referred to at some length. The green chloroplasts which are situated in the more external layers of tissue, so as to be acted on by the sun, under the influence of which they produce the starch supply of the plant. The chromoplasts, are colouring matters other than green, and are generally derived from the chloroplasts. They are most frequently found in the floral envelopes. The leukoplasts are buried in the interior of the plant away from the light, and are specially numerous about the nucleus of the cells. They are colourless bodies so long as they are not exposed to the action of light. The purpose they serve is the formation of starch grains. They form these grains on their external surface instead of within themselves, which is the case with the chloroplasts. On being exposed to light they take on themselves all the functions of the chloroplasts, into which they are, in fact, converted. The tonoplasts were referred to as the agents which promote the formation of vacuoles in the young cells. The elaioplasts are specially connected with the formation of oil. Many very useful notes were given on the cutting, clearing, staining, and mounting of the various tissues, the articles appearing in last year's Pharmaceutical Journal being specially mentioned in connection with this subject, the lecturer mentioned Hanstein's violet as a valuable reagent in the staining of bark tissues.

The Chairman afterwards presented the prizes gained by candidates in the recent herbarium competition. The successful competitors in the Senior Division were: Fred. A. Howorth, R. A. Sykes, Ernest H. Jones, Thomas Wm. Buroh. In the Junior Division the prize was gained by T. O. Barlow.

**Scottish Transactions.**

**EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.**

At the meeting held on January 16, Mr. Alexander Sutherland, President, in the chair, the following papers were read:

**METHODS OF DETERMINING MOLECULAR WEIGHT.**

**BY A. MACKENZIE.**

The author gave an interesting account of Gay Lussac, Hoffman, and Victor Meyer's methods of determining vapour density, and exhibited and described the apparatus employed. He also explained the silver method for acids, platinum for bases, and Raoul's freezing method for neutral salts.

**WEIGHTS AND MEASURES.**

**BY C. A. MACPHERSON.**

The author gave a historical sketch of the origin of standard weights and measures, tracing them from the rude methods adopted by primitive races. He showed how many of these still survived in common use, and also showed the connection between them and the present more refined methods recognised among civilised nations.

In the absence of Mr. McEwan, the other notes were postponed to a future meeting.

The reading of the papers was followed by a discussion, taken part in by Messrs. Coull, Duncan, Hill, Mackenzie, Macpherson, and Sutherland, and, on the motion of the Chairman, a hearty vote of thanks was awarded to the authors.
Great men live most after death, and Raineys name will be remembered as the man of his time who was able to show how nature works by simple physical processes in the most complex organism. In his little room at London Bridge he was surrounded by his many experimental apparatus, microscopes, plants, injecting apparatus, and slides innumerable. Though so quiet and unassuming, he was a man of strong likes and dislikes, and could express himself in a way quietly, severely, satirically, and emphatically, to make folks acknowledge and feel his power; and this power lay in the possession of a large knowledge of science in all its branches, and a vast experience of human nature as seen in students. But this was not all that people felt, for they were conscious of his possessing, and expressing also without reserve, the supremest contempt and scorn for those who gave themselves airs, or assumed a wisdom they did not possess. Even great scientific men—great in public estimation—were not exempt from his scathing criticism. These are a few brief extracts from this charming and sympathetic memoir, written by Dr. W. W. Wagstaffe, of Sevenoaks.

This small volume, according to the preface, embodies work previously published by the author, together with the experience of more recent years. The evolution of modern ideas and beliefs regarding asthma are given. The author favours the view that ordinary intermittent asthma is due to reflex nerve-influence acting on the musculature of the bronchi. The views of most modern authors are referred to, but, after careful reading of the book, one is bound to feel that much of the pathalogy of asthma is still obscure. Berkart's view that in many cases anatomical deficiencies, due to rickets in early life, underlie the condition, and that slight bronchial inflammation and consequent plugging of bronchi and collapse of areas of lung determine the attacks, seems not to have received sufficient attention. Where conjectural pathology prevails, as it does wherever groups of symptoms such as the various forms of asthma are dignified by the name of a distinct disease, treatment is apt to be of an indefinite nature. "The treatment must be aimed first at the removal of any morbid condition from which reflex spasm my arise. Naso-pharyngitis must be cured or a polypus removed. Secondly, any gouty or rheumatic tendency in the constitution must be dealt with by suitable diet and medicine. Lastly, persistent bronchial inflammation and thickening of the air-tubes, as in bronchitic asthma, must be removed by suitable treatment." These imperative preliminaries may prove more arduous than the paragraph just quoted seems to imply, but the reader must allow for limitations of space as well as limitations of art.

ST. THOMAS'S HOSPITAL REPORTS. Edited by Dr. T. D. ACLAND and Mr. BERNARD PITT. Vol. xxii. Pp. i—xviii., 1 to 614. 8s. 6d. London: J. and A. Churchill.

The amount of work accomplished every year at the large metropolitan hospitals is so great that it is an arduous task to analyse it even in its scientific aspects alone. The editors of the present volume are to be congratulated upon the completeness and precision with which they have presented the classified results of the work done in the medical, surgical, and obstetrical departments of their hospital. The value of the volume to medical men is enhanced by original articles bearing on pathology and practice. Among these we notice one by Mr. Edmund White on sterilised dressings and sterilised water (see PA. J.; ante, p. 191). The dressings are exposed to the action of steam at a pressure of 18-20 lbs., i.e., to a temperature of about 125° C. By this means sterilised, though slightly damp, dressings are obtained. If some fibrous absorbent substance could be found capable of bearing dry sterilisation, that is, a temperature of 150° C. for half an hour, it would seem to be a great gain.

To St. Thomas's men the collected annual reports have an interest beyond their great scientific value: they constitute a history of their medical alma mater. The present volume records the sadly premature death of W. B. Hadden, assistant physician. Dr. Hadden was cut off by pneumonia at the age of thirty-seven, when full of energy and promise of a continuation of the great services he had already rendered to his profession. The volume contains also a memorial of George Raineys, who worked at the medical school for sixty years, and the account of whose life is also a record of the changing fortunes of St. Thomas's Medical School, first at London Bridge, then at Surrey Garden, and finally facing the Houses of Parliament. Rainey is remembered as a little, rather handsome old gentleman in a black dress coat and suit, his tall pockets bulging out behind in a rather pronounced manner, for they contained his lunch and often various other things too numerous to mention. He was born at Spilsby in Lincolnshire, and sent to school in the neighbouring town of Louth. At school he said he learned nothing except to cheat the masters. He was first apprenticed to a doctor at Horncastle. The boy ran away after a few days; packed up his clothes, and walked home—a distance of thirty miles. He was then apprenticed in his native town, where he served his time, rising at three o'clock in the morning to study Latin, Greek, French, chemistry and mathematics, yet not neglecting his master's business. He managed to earn a little money by teaching, and in 1824 was able to enter as a student at St. Thomas's. Here he had to pay his way and live as a grinder, or coach, and in the course of time was appointed curator of the museum, and, later, demonstrator of human anatomy and of the microscope.
Correspondence.

Aqua Chloroformi.

Sir,—Kindly allow me to reply to the comments of Mr. W. Martindale and Mr. Percy Wells on this subject, published in your last week's issue. The main point of my paper was the ready attainment of an automatic constant supply of a saturated aqueous solution of chloroform at ordinary temperature, the accomplishment of which, in consideration of the very prevalent use of aqua chloroformi as a diluent, I regarded as a desideratum. Attention was also drawn to the fact that such saturated solution constituted so chloroformi U.S.P., and that three parts of the same were diluted to four constituted the B.P. preparation. Now, Mr. Martindale's first objection is, "the time (twenty-four hours) required to make a saturated solution by Mr. Ellborne's process is too long," here after having figured the process advocated, Mr. Martindale confounds it with the preliminary experiment upon which it was based. Can "too long" be urged as an objection to the acknowledged prototype, the B.P. process for a "gallon" of camphor water, requiring an initial rest of two days? His next objection is "want of definite strength and probable variability of the product, the strength and rate of saturation varying with the temperature." To meet requirements in respect to rate of saturation I specified seven days as the initial period of rest, and as regards the want of definite strength, the solubility of chloroform in water at ordinary temperature is, like that of camphor and certain calcium compounds, of an exceptional character, namely, inversely as the temperature, but the increments of variation for a few degrees either above or below the average atmospheric temperature, 15°C, are so minute that if such refinements of temperature are to be entertained in pharmacy, we must also object to the B.P. process for so important a preparation as lime water, since it has been shown that one part by weight of CaO is soluble in—

770....791....868 parts of water at 10°.....20°.....30° Centigrade.

Yet surely sir, from a practical point of view, and in the absence of any fundamental disparity, to so object w would be straining at a gnats, but Mr. Martindale does more than this, for in his statement that "by the B.P. process the quality of chloroform there ordered can be made by agitation in twenty seconds, and the product is definite in strength," he swallows the camel, for in the light of his own argument about temperature would not the mass of both the "fluid drachm" of chloroform and the 25 fluid ounces of water each vary according to the temperature at which they were measured and on account of the very expansive nature of rectified spirit, would not his suggested product "cum spiritu" prove still more indefinite? Mr. Percy Wells will, I hope, find a sufficient answer in the above.

WILLIAM ELLBORNE.

University College Hospital, W.C.

The Atmosphere of the Sun.

Sir,—Your correspondent, Mr. R. Goodwin Mumbray, does not appear to be very well versed in the physical and chemical constitution of the sun. To reply fully to the questions he raises would occupy very much more space than could be afforded in the Journal, deeply interesting though the subject is. Spectroscopic observations have distinctly shown that the elements existing in the atmosphere of the sun (so far as we now know them), are present there as metals and not as oxides, and even that if oxygen were present in the solar atmosphere, the temperature is such that dissociation would inevitably follow. The light and heat emitted from the sun must therefore be accounted for in other ways than that suggested by Mr. Mumbray, i.e., that they are due to the combustion of carburetted hydrogen by oxygen. Various theories have, of course, been put forward, some physical, some chemical, and the late Sir W. Siemens enunciated at the Royal Institution a theory which, if it could be substantiated, would seem to indicate that the solar heat and light could be maintained to eternity. With regard to the flames mentioned by Mr. Mumbray, it has been shown by Mr. Lockyer that the sun is surrounded by an envelope, the chromosphere, some 400 miles deep, and from this the prominences (the flames) ascend, not for 700 miles, as Mr. Mumbray states, but from 20,000 to 100,000, or even 200,000 miles, at the rate of from 100 to 150 miles in every second. All observers agree that these effects are due to hydrogen chiefly, even if some other element, having a density still less than hydrogen, is not also concerned in the production of this wonderful phenomenon.

St. Leonard's Road, Croydon.

J. H. BALDOCK.

"Habenda Ratio Valutudinis."

Sir,—Mr. Hylop and others who take an interest in the matter may like to have their attention drawn to the following passage in Cicero's 'De Senecute,' chap. xi. —

"Punam tamquam contra morbum sic contra senectutem habenda ratio valutudinis; utendum exercitationibus medicia; tantum cibi et potionis adhibendum ut refecturis vires, non opprimatur. "Habenda ratio valutudinis" is usually translated in this passage, "We must pay attention to health." The above quotation would appear to show the source from which the Society's motto was taken.

Chancery Lane, W.C.

A. H. DAWES.

The same reference to the actual source of the quotation is given by another correspondent. [Ed., Pharm. Journ.]

Amendment of the Pharmacy Act.

Sir,—In view of the Law and Parliamentary Committee being called together on an early date to consider the proposed "Amendment of the Pharmacy Acts," I think the time opportune for the trade at large to bestir themselves in this matter. I venture to suggest that meetings be arranged for in the various towns, in order that chemists may consider and determine what the proposed amending Act should contain; whether it ought to deal with companies, or in what way it could best be drawn up for the best interests of the trade. That this may be done effectually, the Council could authorize the secretary and assistant-secretary to write to the local secretaries, requesting them in the name of the Council to convene such meetings of masters and assistants (whether connected with the Society or not) on an early date for the purposes already mentioned, and that the decisions of the various meetings be forwarded to the Council. I think, sir, in a question of this kind, which ultimately concerns every chemist, it would be a good plan when "light and leading" is desired on any vital subject, for the local secretaries to convene meetings of their brethren for the discussion of such questions and to report the result to the Council. In this way any ground for complaint on the part of those hitherto and at present dissatisfied with the policy of the Council might be removed, and the Council given at least a chance of doing what it has long promised to do, if only backed up by the "voice of the trade."

Dundee.

AN ASSOCIATE.
QUALIFIED ASSISTANTS ABROAD.

Sir,—I daresay this subject has been rehearsed, discussed and discussed on previous occasions, but it is all the better; it should be again brought to the notice of Minor assistants who intend to trap themselves into a foreign engagement, in most cases to better themselves. The average terms as now offered are Rs.180, Rs.190, Rs.210, Rs.250 “out-doors” per calendar month, and passage paid out for a four years’ agreement. On these petty returns (it may be said for professional services rendered) one can easily defy the necessities of life expense; because the first year’s services, after paying for board, washing and the “numerous” other minor expenses which cannot be avoided, leaves a balance that can only partly provide for climatic clothing. At the end of two years’ service, after living a very economical existence, the only harvest reaped is “clear of debt,” and hence it takes the most of the spare rupees of the next two years to provide the passage home, probably with a broken constitution. The above is a correct and true statement of what a minor assistant generally experiences in an Eastern engagement abroad, yet there are exceptions, and that is very often where the establishment belongs to a British principal. One thing particularly to be noted is the number of native and oriental establishments who apply to English wholesale houses for qualified assistants, and although things are represented as being a “bed of roses,” they very often turn out a “bed of thorns.” In concluding, I might safely say that qualified assistants have no right to waste their best days abroad unless they are perfectly assured of getting a fitting remuneration for their foreign services.

Rangoon.

DISAPPOINTED.

AQUA CHLOROFORMI AND AQUA CAMPHORAE.

Sir,—The process for the automatic production of chloroform water, described by Mr. Elborne in your issue of January 12, will be likely to prove useful in institutions like hospitals and public dispensaries where large quantities are required, and where absolute uniformity of strength may not be a cardinal requisite. In retail pharmacies, however, such a process would not be likely to be followed under any circumstances; for apart from the objection pointed out by Mr. Martindale, the official process and so exactly carried out that, on a small scale at least, no improvement on the process is needed. The objection raised by Mr. Martindale to the automatic process applies equally, in my judgment, to the mode of preparation of those of the other medicated waters made by distillation of the dried drug with water. Such waters as those of dill, aniseed, cinnamon, fennel, caraway, and pimento, are bound to vary in strength, and in order to ensure uniformity some process of distillation of the corresponding oil with water, or of solution and filtration, ought to be adopted. I do not say that the need of uniformity is equally urgent in every case, but it would be a distinct advantage if, as a result of the discussion of the matter by pharmacists, the pharmaceutical authorities could be induced to deal with all the members of such a group of preparations at the same time, and as far as possible, on the same lines. I know that in some quarters there is a predisposition in favour of waters distilled from the drugs themselves, but such predisposition is mainly the result of prejudice. I quite agree with Mr. Martindale that the official chloroform water is in many cases too strong to be taken undiluted; and as it is chiefly employed as a vehicle for other remedies the strength might without disadvantage be materially reduced. On one point of interest, though not of importance, my experience does not coincide with that of Mr. Martindale. In his letter, published in your last issue, he says, “We rarely have more than a fluid drachm of spirit of chloroform prescribed in a 6 and 8 oz. mixture.” On referring to my own prescription book, and taking the last dozen prescriptions for 6 or 8 oz. mixtures containing spirit of chloroform, I find that the highest quantity prescribed in a mixture is 6 fluid drachms, and the lowest 2 fluid drachms. The average amount is exactly 190 minims, or slightly over 3 fluid drachms. I should be interested to know whether these figures are exceptionally high, and whether the proportion mentioned by Mr. Martindale more nearly represents the general average. While writing upon the subject of chloroform preparations, I cannot refrain from expressing a hope that the forthcoming issue of the Pharmacopoeia may witness the deletion of one of those preparations, viz., the compound tincture. This is not only one of the least necessary, but also one of the most unpharmaceutical of official preparations. As to aqua camphorae, I feel sure that every pharmacist of experience will agree with Mr. Martindale as to the desirability of substituting the method for its preparation recommended in his letter, for the one prescribed official.

Buxton.

R. WRIGHT.

CORRECTIONS.

Sir,—Will you kindly make the following corrections in the otherwise correct report of my paper in your issue of January 19.—p. 615, col. 2, line 11 for “not in” read “not as in;” p. 615, col. 2, line 14 for “Milk of Sulphate Calcium” read “Milk of Sulphur plus Sulphate of Calcium;” p. 615, col. 2, line 15, delete the words “in this;” p. 617, col. 1, line 23 for “have” read “has,” as the reference was only to the syrup made in April.

Pollokeshields.

THOMAS DUNLOP.

Answers to Correspondents.

Stammerer.—If you had referred to the review on page 361 as directed, you would have found that the book was published by the Savoy Press, London, at 1s. Send that amount to H. Kimpton, 82, High Holborn, London, W.C., and he will supply you with the book.

Wippin and Son.—The formula is correctly rendered from the French.

NOTICES TO CONTRIBUTORS.

* * * Communications should reach the Editorial Department, 17, Bloomsbury Square, W.C., not later than the first post on Wednesday, if publication is desired in the next issue of the Journal; though prompt publication cannot always be guaranteed.

Matter intended for publication must be written in ink, on one side of the paper only, and be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.

Advertisements must be sent to Street Bros., 5, Soho Street, Lincoln's Inn, W.C., where copies of the Journal may be purchased, and instructions from Members respecting the transmission of the Journal to the Secretary—Mr. Richard Bremridge—17, Bloomsbury Square, W.C.; otherwise delay may be caused.

Communications received from Messrs. Ainsworth, Baldock, Balphoon, Baxter, Brown, Buck, Cartege, Cocks, Dunlop, Elborne, Everett, Hewlett, Hill, Kemp, Leaming, Lenton, Mair, Mann, Munbray, Peck, Reeves, Robinson, Russell, Schacht, Shapley, Sherborn, Simmonds, Simpson, Vaughan, Wiggin, Wright,
"THE MONTH."

The Alkaloids of Ipecacuanha.

In the Bericht issued by the firm of E. Merck for 1894—just received—it is announced that the manufacture of the alkaloids of ipecacuanha, described in this Journal by Paul and Cownley (ante, p. 111.), has been undertaken by that firm, and that it is now prepared to supply both of the pure alkaloids, emetine and cephaline, or their salts, as well as the mixed alkaloid of ipecacuanha, which has hitherto been known by the name of "emetine.

This is a striking evidence of German enterprise in connection with chemical industries, which unfortunately has little corresponding manifestation in this country. In the account given of these alkaloids in the Bericht, it is stated, as the result of experimental trial, that the view put forward by Kunz-Krause in opposition to Paul and Cownley could not be adopted, but that the results obtained by Paul and Cownley in regard to the composition and character of emetine and cephaline were fully confirmed in all essential particulars.

In connection with this subject it may be mentioned that Paul and Cownley have isolated a third ipecacuanha alkaloid, and they have succeeded in arriving at some knowledge of its general character. It exists in very small amount in the root, and has been obtained by shaking the ammonical liquor—from which emetine and cephaline have been separated—with chloroform, in which the alkaloid is very soluble. Ether dissolves this alkaloid very sparingly, but by evaporation of the ether solution the alkaloid has been obtained in transparent rhombic prisms, of a pale lemon-yellow colour, which rapidly darken when exposed to light. The alcoholic solution darkens much more rapidly. The very small quantity of this alkaloid obtained was insufficient for full examination, but it appears to have a higher molecular weight than emetine or cephaline, and a melting point of about 138° C. It is distinctly alkaline, neutralises acids, and forms salts, which appear to be unstable.

Solutions of the salts and of the free alkaloids appear to undergo rapid alteration under the influence of light, with production of dark yellow-brown coloured substances. In this respect the newly isolated alkaloid presents a marked contrast to the emetine and cephaline, salts of which are unaffected by light, though the alkaloids very soon acquire a yellow colour when exposed to light.

Preparation of Hydrazine.

The preparation of this interesting body, discovered by Curtius in 1839, has been both indirect and difficult. The methods have generally depended on reduction, or reduction and hydrolysis of complex diazo-, nitrosoamin- or nitramine-derivatives of the alliphatic series, such as amido-quinain (NH₃C(NH₂)N₂H₃), or diazo-aceto ester (CH₃N₂COC₂H₅). Duden has now been able to prepare this compound from an inorganic salt by reduction. For this purpose he uses the salt obtained by the action of sulphurous acid on potassium nitrite—a compound of potassium sulphite with nitric oxide, K₂SO₃N₂O₅, and by reducing this in alkaline solution at a low temperature with sodium-amalgam he obtains hydrazine and potassium sulphate. The first stage consists probably in the reduction to a salt of hydrazine, which is then hydrolysed by alkali according to the following equations:

I.

\[
\text{KSO₃N₂O₃ + 3H₂} → \text{KSO₄H} + \text{N₂H₄ + H₂O + KOH}
\]

II.

\[
\text{KSO₃N₂H₄ + KOH} → \text{K₂N₂H₄ + K₂SO₄}
\]

The hydrazine was identified by the formation of the sulphate and the compound formed with benzaldehyde-benzal-azin (Ber., xxvii, 3498).

Critical Point Having previously shown how more traces of alcohol in chloroform of liquids or ethyl chloride cause a notable variation in the temperature of the critical points of those liquids (ante, p. 326), R. Plötner now deals with the influence of solids in a similar direction when dissolved in the liquids. Borneol, cineol, terpinol, phenol, guaiacol and iodine were each dissolved in pure sulphuric ether (c. 189°), alizarin was dissolved in alcohol, and borneol in ethyl chloride (c. 181°), and the following results are recorded:

Borneol was found to remain dissolved in ether vapour, alizarin in alcohol vapour, etc., etc., at temperatures below the fusion points of the respective solids (Comp. rend., cxxvii., 64).

Schneggas and Brunnert report on llicene, a new hydrocarbon, illicene, which they have found in combination with fatty acids in young holly bark. The body crystallizes from alcohol and melts at 182°-183°; ultimate analysis indicated the empirical formula C₈H₁₀, and determinations by the Raoult-Beckmann method the molecular formula C₈H₁₀O. Young dry bark contains about 2 per cent, the leaves much less. The authors are prosecuting their investigation of this interesting body (Archiv. xxviii., 532).

Salt of Nicotine.

Parenty and Grasset, in a paper on the manufacture and physiological properties of the oxalate and other salts of nicotine, show that whilst the fatal dose of pure nicotine is from 20 to 21 Mgm. per kilo. of animal, that of combined nicotine is 70 Mgm., whilst that of the quadrroxalate may be as much as 150 Mgm. per kilo. The physiological effects of the latter illustrate, in a minor degree, the same general character as pure nicotine—contraction of the pupils, paralysis and convulsions, salivation, etc.—but it was proved by experiments that animals could become accustomed to take larger quantities daily than the normal fatal dose (Comp. rend., cxxvii., 1873).
Barth has described a method of determining the purity of the salts of zinc, either by determining the excess of acid or the actual amount of zinc. The process depends on the use of standard alkali and of the two indicators—tincture of holly-hock (rose trimère) and phenol-phthalein. The analysis is conducted in two stages, and is as follows:—The salt under examination, the sulphate, nitrate, etc., is dissolved in water, and the excess of acid, if any, determined by titration with decinormal potash, using tincture of holly-hock as an indicator. The reaction is complete when the colour changes to green, but it is necessary to work with very dilute solutions to obtain accurate results. With another portion of the salt a solution is made and alkali added till the red colour of phenol-phthalein is permanent. The amount of alkali required to react with the zinc is now obtained by subtracting the volume of alkali used in the first operation from that of the second, and then calculating for the formation of the salt (ZnO)_{2}ZnSO_{4}, or every cubic centimetre of 1/10M potash used will represent 0.003925×5 grammes of pure zinc (Bull., xiii., 82).

A. Vectorite thinks he has discovered a new element among the by-products left after the extraction of aluminium from red bauxite. The liquors contain chiefly sodium carbonate and sulphate, together with chromic, vanadic, molybdic, silicic, arsenic, phosphoric, and turgetic acids, as well as alumina, magnesia, lime, etc. The supposed element exists in the liquors in the form of an acid, which is soluble in water and forms yellow crystals. The solution is not precipitated by sulphuretted hydrogen, but may be obtained on evaporating its solutions as a bluish-violet oxide, which subsequently becomes further oxidised and lemon-yellow in colour. The latter compound, which probably corresponds to the formula R_{2}O_{3}, has marked acid tendencies, and forms characteristic compounds with different bases. The spectrum of the new body is similar to those of nickel, cobalt, and copper, in the green, blue, and violet, and it is suggested that Dr. Vector has discovered one of the missing elements predicted by Mendeleeff in the nitrogen-phosphorus group (Bull. de la Soc. Chim. [3], xi., 1155).

The Protomorphic State. A. Villiers has previously suggested (ante, p. 608), that nickel and cobalt sulphides may, at the moment of their formation, be in a different condition to that in which they normally exist, and this condition he now proposes to term the "protomorphic state" (état protomorphique). It appears also in the case of other sulphides, and is more pronounced in those with nickel or cobalt. Recently precipitated zinc sulphide, for example, does not change immediately in the cold, though very rapidly when heated, and it is probable that manganese sulphide may also be found to illustrate protomorphism (Comp. rend., cxx., 97).

Melaethin. W. v. Schulz reports upon the physiological action of the body melaethin isolated by Greenish from the seeds of Nigella sativa. This substance has been shown by Kober to resemble the sapotoxin of quillia bark, and by Schulz to be a member of the homologous series of saponins of the formula C_{n}H_{2n+2}O_{n}. The experiments made showed that melaethin exhibited the typical physiological action of the most poisonous sapoxtins (sapotoxin, cyclolim); the lethal dose for cats was determined to be about two milligrams per kilogramme (Pharm. Zeitachr. f. Russland, xxxi., 51).

Silver Sulphide. A. Ditte describes how silver sulphide, kept cool and in the dark, changes in a short time in the presence of a saturated solution of potassium sulphide. From black it turns red, forming small crystals, which are but little soluble in the solution, and have, when dried in an atmosphere of carbon dioxide, a composition which may be represented by the formula 4Ag₂S₃K₂S₂H₂O. The same compound is formed on boiling together silver and potassium sulphides. It is altered by light and decomposed by water, the latter reaction allowing the silver sulphide to be obtained in the form of greyish-black crystals. A double silver and sodium sulphide can also be prepared, though not in the cold, the red crystals having the composition 3Ag₂S₃Na₂S₂H₂O, and being at once decomposed by water (Comp. rend., cxx., 91).

Preparation of Amorphous Silicon. A. Amorphous Vigoroux by the reaction of magnesium with silicon, the—SiO₂+2Mg=2Si+2MgO. The silica (180 Gm.) and magnesium (144 Gm.) are mixed with magnesium oxide (81 Gm.), and heated in a furnace previously heated to a red heat. The reaction occurs in two or three minutes, raising the temperature to 540°, and a mass is obtained which, after drying, yields a brownish, homogeneous powder, containing from 99.09 to 99.60 per cent. of silicon, when pure materials are employed (Comp. rend., cxx., 94).

β-Oxycholinolone. By the prolonged action of 50 p.c. sulphuric acid on chinchone at 120°, α-oxychinchone and β-oxychinchone are formed. Jungfleisch and Léger describe the latter as occurring in small prismatic needles when crystallised from strong alcohol. These are colourless, anhydrous, and strongly dextroglyrate, melt at 273° (corr.), but at about 250° become slightly coloured. The compound is almost insoluble in water, but soluble in cold alcohol and very soluble in warm. It is an energetic base, and its formula is C_{21}H_{22}N_{2}O_{4}. It forms two classes of salts with monobasic acids—C_{21}H_{22}N_{2}O_{4}·H₂O or C_{21}H_{22}N_{2}O_{4}·2H₂O. Most of the salts are distinctly crystalline (Comp. rend., cxxi., 1268).

Caffeine and Cheap Tea. Caffeine, for which there seems to be a considerable demand, is chiefly made from the sweepings of tea warehouses, which can be purchased at about 4d. or 5d. per lb. Recently some enterprising German companies have hit upon a method of getting their caffeine for next to nothing. The tea sweepings have been bought in the London market, taken to Germany, and all the actual dust tea removed by sieving, and the coarser particles of tea, after passing over a magnet to remove particles of iron, have been returned to the London market and offered as drinkable tea. The character of this tea was detected by the use of a lens, which revealed the particles of wood arising from the opening of tea chests in dock warehouses. These is impossible to remove from the tea sweepings. The residual dust serves as the source of caffeine.
Purity of Drugs, etc.

L. F. Kebler has examined samples of honey which contained an excess of chloride and was supposed to have been adulterated with glucose, in the preparation of which hydrochloric acid had been used. On inquiry it was found to have been accumulated from a "salt marsh," and a complete examination was therefore made to determine whether the environment might not account for the excessive proportion of chlorides. The result was as follows:—Average percentage of water, 16·13; ash, 0·26; reducing sugar, 68·19; pollen-grains in abundance; sulphates, a trace; chlorides, excessive.

It was considered, therefore, that the samples represented glucose. Three samples of pyrogallic acid examined by the same writer had the following melting points—116°, 115°, 116°, and 117°, respectively. They were probably mixtures of pyrogallic acid (m.p., 131°) and catechol (m.p., 111°). Of four samples of light oil of wine, varying in price from 80 cents to $4·50, one was entirely fusel oil, two were mixtures of ether, alcohol, and small quantities of heavy oil of wine, and the fourth was approximately a mixture of equal parts of commercial ether and heavy oil of wine. Four out of ten samples of oil of sassafras approximately complied with the U.S.P. requirements, one consisted of commercial safral, and the remaining five of "artificial sassafras oil," produced by fractionating camphor oil. Finally, examination of two samples of ipéceauhana root by Kebler's process showed that the thick annulated or "fancy" root (1·67 per cent. alkaloid found) is frequently not as valuable as the "winy" root (2·39 per cent. alkaloid found), whilst titration with volumetric acid solutions gave most encouraging results (Am. Journ. Pharm., ixvi, 26).

Piper Clossi.

H. R. Herlaut has contributed to the study of useful plants from the Congo territory, by examining the fruits known as "Poivre de Clusius." He finds that they contain 11·5 per cent. of volatile oil and 50·5 per cent. of piperine, either free or in the form of a compound which is decomposed by solvents. The detection and localisation of the latter body can be best effected, according to the author, by the persistent yellow colour it produces in contact with hydrate of chloral; it exists only in the albumin. In assisted nature, the action of sodium salicylate was utilised to separate resins as matters; the amount of piperine thus determined proved to be less than is present in black pepper, but Herlaut thinks they could be used either as a source of piperine, or, if deprived of part of their volatile oil, as a condiment. Although its structure resembles that of cubee the fruit is to be classed with the peppers containing piperine (Acad. Roy. de Méd. de Belgique, 1894, 115).

Tolu Balsam.

P. Oberländer has subjected to a detailed chemical examination, and finds the resins portion to consist of tolu-resinotannol in combination with cinamamic and benzoic acids, the latter in small proportion only. In addition the balsam contains 7·5 per cent. of an acid, aromatic, oily liquid, principally benzy1 benzoate, with a little benzy1 cinnamate and 0·05 per cent. of vanillin. Neither styracem, free benzy1 alcohol, or phenyl-propyl cinnamate could be detected. The balsam is a pathological product, and as such, as well as in its chemical composition, resembles balsam of Peru. The lamina of the leaf of the Toliusfera. Balsamum L. contains schizogenous ducts just on the boundary between parenchyma and spongy parenchyma, and in the midrib. Small twigs exhibit a number of such ducts, but during the secondary growth they are completely thrown off and no new ones formed. The bark of older stems, which is entirely free from schizogenous ducts, was found to contain phloroglucin, tannin, phlobaphene, traces of wax, sugar, and coumarin, but none of the constituents of the balsam (Archiv., ccxxxi, 559).

Fistula draws attention to a paraffin oil that is being offered to replace the Theobroma, oil for the theobroma. A sample examined by him was white with a slightly yellow tinge and distinct blue fluorescence, possessed a specific gravity 0·869, and boiled at over 300° C. An adulteration with such a body could readily be detected by the usual saponification methods (Forschung's Berichte, i, 543).

Arabinochloralose and Xylochloralose.

It has been found by Richet and others that by substituting for the glucose used in preparing chloralose other sugars such as arabino or xylo, similar compounds to the soluble and insoluble varieties of glyco-chloralose may be obtained in each case. The arabinoose combination possesses but one half the toxic power of glyco-chloralose, and the convulsions produced by the latter, resembling those occurring in cases of strychnine poisoning, are not observed when poisonous doses of arabino-chloralose are administered. On the other hand xylochloralose causes similar convulsions to glyco-chloralose but possesses no hypnotic power. It would appear possible, therefore, by combining chloral with various sugars, to prepare a series of chloralose-like bodies, of which the hypnotic and stimulant effects are dissociated and varied within extensive limits (Repetitoire [3], vii, 29).

Activity of Digitalin. Dr. G. Bardet has compared the therapeutic activity of crystallised digitalin with digitozin, and concludes that the former is the only product obtained from digitalis possessing a really definite, constant, and well-known action. From a therapeutic point of view, Digitozin differs both from crystallised and amorphous digitalin, and is described as an indefinite mixture, with variable activity. Amorphous digitalin probably resembles digitozin in containing a glucosidal body possessing considerable activity, which, however, may vary. It is recommended that crystallised digitalin alone should be prescribed (Journ. de Pharm. [6], L, 27).

Solubility of Bromide.

M. Fontes-Diacon finds that the solubility of anhydrous strontium benzoate in ethyl alcohol is practically constant between 0° and 40°. 100 Gm. of absolute alcohol dissolving about 64·6 Gm. of the salt, and forming a solution of which the density is 1·210 at 0°. Saturated solutions allowed to stand in stoppered bottles deposited in the course of several months fine crystals belonging to the orthorhombic system. On analysis these were found to contain 688·700 of alcohol, and composition is probably represented by the formula—2Br, Sr, 5C1H6O. (Journ. de Pharm. [6], 1, 69).
M. Vogtherr has subjected the fruits of *Randia dumetorum*, which are used in the East Indies as an emetic and as a remedy for dysentery, to chemical and microscopical examination. The poisonous properties of these fruits he attributes to a saponin, randia saponin, and to an acid, randic acid, which he has isolated from the pulp. The former of these bodies does not appear to stand in any near relation to Kobert's saponins; it resembles quillaja sapoxygen in many respects, but differs in the proportion of sapogenin, yielded by its decomposition. Randic acid resembles Kobert's quillsic acid. The fruits were also found to contain a tannin and fat (Archiv., cxiii., 489).

In some further notes on the structure of this plant, Professor Sanguinaria Canadensis. Bastin states that the red or orange-coloured secretion found in the rhizome is chiefly contained in distinct cells, which are either isolated, flowered, or irregular chains and distributed among the parenchymatous tissues of the middle bark and large pith. In the inner portion of the middle bark, however, and in the inner bark, occur chains of cells which are longer, more regular, and contain a yellow rather than an orange-red secretion. The cells composing the chains are also much narrower and more elongated than are the ordinary secretion cells. In most instances there is no apparent communication between the cells of these rows, the transverse partitions between the cells being imperforate. In a few instances, however, particularly in the inner layer of the bark, there is demonstrable connection between the secretion cells of the chains, which thus form a true tanniferous tissue, essentially like that occurring in many other of the Papaveraceae, though of course much less complex in its development." These milk-tubes are seldom more than a dozen cells long and are seldom branching, the reticulate form of tanniferous tissue being found only in the most rudimentary stage of its development. The secretion cells contain resins as well as alkaloidal principles, and samples available that the salts of sanguinarine are more abundant in the large orange-red secretion cells of the pith and outer portion of the middle bark, while those of chelerythrine are more abundant in the smaller yellow cells and tanniferous tubes of the inner bark and inner part of the middle bark (Am. Jour. Pharm., lxvii., 4).

Dr. F. Ranwez directs attention to the adulation of saffron by the addition of the stamens from the inner surface of the perianth. The detection is easy when the saffron is whole for, though the stamens are yellow like the styles, the stigmas are red and usually attached to the styles, and in addition the form of each part is very characteristic. In powdered samples, however, detection of the adulation is not so simple. When stamens are present to any extent the reddish tint of the powder is, of course, diminished, but there is no principle in the stamens that can aid in their detection by chemical means. It is necessary, therefore, to depend upon the anatomical structure, which is completely different in the male and female organs of the flower. The inner surface of the anther is formed of a layer of large cells the walls of which are thickened by characteristic spiral bands. Such bands occur in nearly all stamens, but their form and size varies with the species of plant. Again, though saffron normally contains a little pollen, when stamens are present the proportion is greatly increased (Am. dr. Pharm., l., 6).

Bertrand and Maillyre conclude, Pectic Fermentation has undergone that pectic fermentation exists in solution in the cell-sap of acid fruits as well as in the roots of carrots, insoluble pectic being absent. But in the juice of acid fruits the presence of the ferment may be masked by the acidity of the fluid, its action being rendered apparent after neutralisation only. Pectic fermentation is considered to depend upon the relative proportions of ferment, calcium salts, and free acids (Comp. rend., cx., 110).

C. G. Hunkel gives the results of a re-determination of the physical constants of the oil distilled from the fresh leaves and a few cones of *Abies balsamea*. Analytical results indicated the presence of a large amount of an oxygenated compound. The specific gravity of the oil was 0.8992, and the refractive power [α] was 32°46' (100 Mm. tube), the determinations being made at 20° C. The boiling point was unstable, and the first fractions obtained on distillation had an acid reaction, the decomposition of an ester being thus indicated. After saponification of the mixed fractions and distillation of the alkaline liquid with aqueous vapour, oil came over clear at first, but subsequently the distillate crystallised. M.p. of crystals, 135°-139°, in a sealed tube; s.g. of oil, 0.8786, and [α] = 30°-22'. On re-fracturation this oil congealed in the condensing tube, crystals having a m.p. of 201°-202° being formed. The fraction of oil distilling at 160°-166° had s.g. 0.8796, and [α] = -30°-36'. It yielded but little pine no nitroso-chloride (crystals melting at 101°), but from the mother-liquor, after freezing for twenty-four hours, three separate crops of crystals were obtained, melting at 134°-5, 136°-136', and 136°-5-137°, respectively. The total quantity was too small, however, for further examination. The fraction of oil distilling at 185°-186° had a more distinctly betherinethic odour than the preceding one, and had a.s. 0.8719, whilst [α] = -31°-38'. The crystals melting at 201°-209° consisted of large shining plates, and were found to correspond with borneol, the same product being yielded by the fractions distilling at 168°-172°, and 172°-185°. The acid present was proved to be acetic, and it would appear that the oil contains pinene and bornyl acetate, both being levogyrate (Am. Jour. Pharm., lxvii., 9).

Oils of Spike G. Massol has had an opportunity and Lavender of determining and comparing the rotatory power of genuine oils of spike and lavender. The determinations were performed at 15° with a Laurent's polarimeter, a 100 Mm. tube being employed, and yielded the following results, the calculations being based on the formula [α] = c

| Oil of Lavender | -3°-70 | 0.980 |
| Spike | +9°-66 | 0.985 |

It is pointed out that these figures differ from those
formerly recorded, Buignet having published the following:—

<table>
<thead>
<tr>
<th>Cyclist</th>
<th>Rotation</th>

Samples of oil kept by Mascol in well-stoppered bottles, and exposed to diffused light for thirteen months, showed no variation in rotatory power. He concludes that Fluckiger's statement that the rotatory power of essential oils must vary with their extremely variable composition is correct, and that, in view of the differences in the results published by different observers, the physical constants referred to cannot be depended upon to discriminate between the oils of two closely allied species as Lavandula vera and L. spica (Journ. de Pharm. [6], 1295).

Pine Tar and Croceata. A. Renard finds that 66 p.c. of the products of pine tar, distilled between 200° and 220°, correspond to boiling point with ordinary croceata. The portion distilling between 200° and 210° consists of monophenol, 40 p.c.; guaiacol, 20·3 p.c.; cresol and its homologues, 37·5 p.c.; whilst the loss is 2·2 p.c. The fraction passing over between 210° and 220° does not contain guaiacol. Generally, the composition of pine croceata may be regarded, with reference to its guaiacol strength, as intermediate between that of the croceoses of beech and oak (Comp. rend. cir., 1276).

Vegetation and Atmospheric Ozone. The influence of vegetation on the formation of atmospheric ozone, has occupied the attention of several observers from time to time, but the results of their investigations are more or less contradictory. As the result of more than 700 observations conducted during the months of July, August, September, and October of last year, J. J. Pearson has definitely formed the opinion that the production of ozone is favoured by vegetation. His experiments were performed at different times and in different places, with iodised starch paper, and he finds that the quantity of ozone produced is greatest when the surrounding vegetation is most active. During the whole course of the experiments, ozone was found to be present continually, both day and night, in country districts; but in Paris, during October, it was only detected during stormy weather with its accompanying atmospheric disturbances (Comp. rend., cir., 1295). Some time ago G. J. Peirce showed how the haustoria of different parasitic plants penetrate the living tissues of the host plants (Ph. J. [3], xxiv., 345), and he has more recently shown that the same power exists in the roots of the pea, bean, turnip, and white mustard (Bot. Zeit., iii., 169), seeds of the two latter enclosed between halved potato tubers forcing their roots through the substance of the potato, and even piercing the external cork layer in twenty days. No root-hairs were developed and no corroded starch grains were found, but the passage made by the root was surrounded by torn, dead, brown-walled cells, and it was concluded that the penetration must be due to mechanical pressure and not to the action of a diastatic ferment. The external tissues of branches of an Impatiens, leaves of Echeveria and of an aloe, a leaf-stalk of rhubarb, and a stem of Euphorbia were also penetrated by the roots of seedling peas. The editor of Natural Science recalls an instance recorded by Rendle (Journ. Bot., 1893, 193), in which shoots had grown inwards from the base of the eyes of a potato tuber, penetrating its substance and giving rise to thread-like roots and small tubers, the latter eventually bursting the skin of the main tuber by the force of their growth. The layer of cells lining the cavities were formed in the old potato lost their contents and their walls became corky, while layers of cork cells were formed on the surface of the young shoots and tubers.

Experiments are described by E. Assanl that seem to indicate the possibility of glycerin affording nutrition to plants under certain conditions. Filaments of Spirogyra, previously deprived of starch by being kept from the light for a prolonged period, on being immersed in a solution of glycerin, produced fresh starch in 24 hours. This change, however, was only effected in the presence of light. The strength of the glycerin solution employed (0·2 per cent.) enabled the experiments to be continued for a prolonged period. A stronger solution (0·5 per cent.) was used with advantage for experiments of brief duration, but the presence of more than 1 per cent. of glycerin was found to cause ill-effects, whilst if the proportion were below 0·1 per cent., no appreciable alimentary effect was produced (Ann. agron., and Journ. de Pharm. [5], xxx., 558).

Professor A. M. Edwards dispenses with the use of a funnel in cases of a difficult filtration through paper, replacing it by a piece of celluloid, in which numerous holes have been punched. This is bent into the shape of a funnel and supported in a retort stand ring. When not in use the celluloid can be washed and put away flat like a piece of paper (Chem. News, 86, 40).

Hydrogen Peroxide in Green Plants. A. Bach describes a new re-agent for demonstrating the presence of hydrogen peroxide, or other peroxide acting in a similar manner, in green plants (ante 173). The reaction is based on the fact that perchromic acid in ethereal solution readily converts aniline, in the presence of free acid, into a violet colouring matter. The best results were obtained with a solution containing 0·03 gm. of potassium bichromate and 5 drops of aniline per litre. On adding to a mixture of 5 C.C. of the solution and 5 C.C. of a dilute solution of hydrogen peroxide, equivalent quantities of different acids, and noting the time that elapsed before the coloration appeared, oxalic acid was found to act most decidedly and rapidly. The method adopted, therefore, was to mix 5 C.C. of the solution to be tested with the same quantity of the bichromate and aniline solution, and then add 1 drop of a 5 per cent. oxalic acid solution. A rose-violet coloration is produced in the presence of hydrogen peroxide, and readily contrasted with the result of a blank experiment, in which 5 C.C. of the ferrous 5 C.C. per cent. by tincture by an 1 drop of the acid solution are mixed. The leaves of plants were treated with 1 per cent. oxalic acid solution, and the liquid subsequently tested as
above. Of twenty-five species of plants, thus examined, eighteen gave a positive reaction (Comp. rend., xix., 1218).

Sir B. W. Richardson considers iodine to be one of thereadiest and best of disinfectants, and describes anew his methods of using it. Rags dipped in an alcoholic solution of iodine may be suspended in rooms requiring disinfection, or a box containing iodine may be covered with muslin and exposed on the mantelshelf, or, again, the iodine may be quickly dissipated over large areas by issuing a fine spray containing it. It is described as rapidly destroying the organic products which are the cause of disagreeable odours, acting in the same manner as chlorine, bromine, or ozone, being nearly as powerful as the first-named (Asclepiad., xi., 157).

What is probably the smallest, compact, lightest, and most compact practicable portable galvanic cell, made is the Cape-Farad Battery. Battery, which yields a current of 2 amperes at a voltage of 1.8. It consists of a zinc cell 11/16 inch in diameter and 3 3/4 inches long, closed with a hard rubber stopper, and containing an electrode of fused silver chloride cast upon a zigzag silver wire, one end of which extends through a stuffing box in the cover and forms one pole of the battery. The zinc cylinder forms the other pole. Hard rubber discs hold in position the silver chloride rod, which is enclosed in textile material, while the space between it and the zinc is filled with fibrous material saturated with the electrolytic liquid. A four-cell battery with case weighs but little more than a pound of performing useful work (Sict. Amer., lixi., 43).

Powdered Cinnamon. Pflister observes that of late years the quality of the lower grades of cinnamon bark and of powdered cinnamon, which is largely produced from the broken bark and siftings of such grades, has been very low. An attempt at improvement has recently been made by adding to such cinnamon the stalks of cassia buds which possess an unusually powerful odour of cinnamon. In the powdered drug such an admixture can be recognized by the small papillate thick-walled hairs, long sculptured cutinized epidermis cells with large lumen, and the small spiral vessels. Pflister considers that such addition of cassia stalks to powdered cinnamon is admissible insomuch as by the comparatively large proportion of volatile oil they contain, they tend to raise rather than lower the quality of the powdered drug Forschung's Erleichte, I, 540.

Under the sensational title of "A Revolution in Voltal Electricity," H. N. Warren publishes somewhat scanty details regarding a new form of voltaic cell, which is described as possessing special advantages in certain cases. It is made flat, with sliding carbon plates which have been previously impregnated with boron, soaked in solution of platinum oxide, and heated to redness in an atmosphere of hydrogen. The plates are enclosed in a teak-wood box, and a flat porous cell encloses the zinc element. The only information given respecting the exciting agents is to the effect that the outer cell contains a "specially prepared manganese salt in admixture with other substances." The battery (one cell) is said to be "capable of producing 3 volts, and giving a constant current from 2 to 2 1/2 for almost unlimited duration." The cells are arranged in series of three, and with twelve small ones arranged in series an arc was produced between carbon points, "more than the naked eye could bear," whilst "over two feet of platinum wire was raised to incandescence," and the heat from the arc produced ready fused titanium, chromium, and tungsten, and volatilised platinum in quantity. The conclusion of the all too brief description states that the new cells are unrivalled as a lighting agent for lamps, and give a useful form of battery, usually a clock to drive a motor, and three for the entire electro-chemical work of a large laboratory (Chem. News, lxxi., 2).

Determination of the method of starch determination which depends upon the use of diastase, that renders it much shorter and easier, as well as fairly accurate, whilst a further slight modification renders it the most accurate method known. The substance in which starch is to be determined is finely powdered, and enough to contain at least half a gram of starch is placed in a flask with about 50 C.C. of water, and 1 or 2 C.C. of aqueous malt extract, prepared by covering powdered dry malt with water containing 15 to 20 p.c. of alcohol and filtering off the infusion after a few hours. The mixture is then boiled to boiling, with frequent shaking in order to prevent the formation of clots of starch. After boiling for a minute, cool to 50°-60° C., and add 2 or 3 C.C. malt extract, then heat slowly for 15-15 minutes till the mixture begins to clear, and test with iodine solution. If there is any blue coloration, the treatment with malt extract must be repeated, but if all the starch is changed, cool the mixture, make up to a definite volume, and filter through linen or muslin. An aliquot part of the filtrate, containing 0·2 Gm. of 0·3 Gm. of starch, is placed in a 100 C.C. flask with 50 C.C. HCl (30 per cent.), and water to make up 60 C.C. Boil moderately for thirty minutes on a sand bath. Complete conversion will now have taken place, and on cooling the solution and nearly neutralising with sodium bicarbonate, the iodine, as iodine monochloride, is precipitated and detected by Fehling's solution. The whole operation is said to occupy less than two hours (Journ. Am. Chem. Soc., xvii., 64).

Kino of Kino in Wine. Kino has of late risen to the unusually high price of about 14s. per lb., in consequence of the demand that is stated to have arisen for it in giving colour and "edge" to port and Burgundy wines. As a consequence of its scarcity other varieties of kino are coming into the market, notably Bengial or Pulas kino (Butea frondosa), which is distinguished by having particles of bark always attached to it and by its ruby colour. African or Gambia kino (Pterocarpus erinacaeus) has also been imported. It is smaller, brighter, and of a more purplish red than ordinary kino. This kind is the original kino, deriving its name from the African name of the tree "Kano," and its importation appears to date from about the year 1811. It is somewhat singular that it does not more frequently enter commerce, since the tree grows from Senegambia to Angola, and the tinctor of this kino has the reputation of not becoming gelatinous when kept.
NOVEL LABORATORY DEVICES.

AUTOMATIC PIPETTE.—The pipette here illustrated has been devised by Emil Greiner (Journ. Am. Chem. Soc., xvi., 643) for use when it is required to take a great number of samples of a given liquid in succession, and all of the same volume. The construction of the pipette, which automatically takes up the exact volume of liquid required, is sufficiently evident from the illustration, and it has been found practicable to make it in all sizes required up to 60 C.c. The necessity of drawing up the liquid by the mouth and watching the mark intensely obliterated, and the instrument would appear to be peculiarly adapted for use in cases where pipettes are used often and accuracy is desired.

LYSIMETER FOR DETERMINING SOLUBILITIES.—The lysimeter (lysis, solution) has been found very serviceable by Charles Rice (Journ. Am. Chem. Soc., xvi., 715) in determining the solubility of substances at high temperature, when the solvent is highly volatile. The idea upon which it is based is the separation from the original solution, which usually contains an excess of the substance in suspension, of a filtered portion at the same temperature as that of the former. The glass tube a is 15 Cm. long and 1 Cm. in external diameter, and is provided at one end with a well-ground stopper c, while the other end is cup-shaped and connected with the main tube by a contracted neck. A carefully ground glass bell e, having a perforation, f, at the bottom, is made to fit this cup, as is also the stopper b. Assuming that the solubility of morphine in boiling alcohol is to be determined, enough liquid must be provided to allow of at least one-half the tube a being immersed. The stopper c, and glass bell e, the latter filled with absorbent cotton and fastened in thin platinum wire, having been placed in position in the tared tube, alcohol is boiled in a beaker or test-tube, and saturated with morphine, after which the prepared tube is immersed. When the apparatus has acquired the temperature of the boiling liquid the stopper c is removed, whereupon the liquid filters upward through the cotton. To secure uniformity in the liquid, the filtered portion should be allowed to flow back once or as many times as may seem necessary. The stopper c is then re-inserted, the tube with

drawn and inverted, and the glass bell removed and replaced by the stopper b. After cleaning the tube with alcohol, it is allowed to cool, and the weight of the contained solution then determined. On transferring the contents to a tared beaker or capsule and evaporating, the weight of the dissolved morphine will be found.

CONVENIENT BURETTE CLAMP.—A convenient form of burette clamp is made by Clarence Quinan (Journ. Am. Chem. Soc., xvi., 719), in accordance with the accompanying sketch, a simple wedge holding the tube in position. The holder is made, preferably, of maple, and the wedge of hickory or other hard wood. The surface of the latter should be slightly curved to ensure accurate contact, and cork is found unnecessary on the bearing parts, since very slight pressure on the upper end of the wedge causes the tube to be held with great rigidity.

HYDROGEN SULPHIDE GENERATOR.—The apparatus described by H. G. Schanche (Journ. Am. Chem. Soc., xvi., 868) has been proved, during seven years of use, to furnish always an absolutely uniform supply of gas. From the reservoir A, the acid passes into the generator B, which contains ferrous sulphide a b resting on coarse pebbles at a. The ferrous chloride formed collects in C, whence it may be removed easily from time to time by opening the cocks d and f, and so allowing the solution to flow through the lead pipe g, into a drip pan under the table on which the apparatus stands. The quantity of gas supplied is controlled by regulating the flow of acid by means of the cock e, and the supply is kept uniform by the height of the column of ferrous sulphide. As the acid percolates through this it is completely neutralised. D is an ordinary wash-bottle, and the shelf E, on which the generator stands, is easily slipped off its bracket, so that the generator can be readily removed for cleaning or re-charging.

SAFETY ATTACHMENT FOR RIDERS.—An arrangement, devised by Chas. E. Parker (Journ. Am. Chem. Soc., xvi., 764), appears to possess advantages as regards simplicity, lightness, and adaptability, over others employed in manipulating the weighing riders of balances. A light glass rod m (Fig. 3), is fixed
parallel to the beam, behind and slightly above it. Then a piece of sheet brass—to which a piece of hair-spring from a watch, a, is soldered—(Fig 1, b) is bent, as shown in Figs. 2 and 3, to form a sleeve upon the rod c, together with a prong d, in opposition to the hook e, Fig. 2, by which the rider is usually lifted, and an extension f, under the rod m, which thus limits the rotation of the sleeve and prong in one direction. The usual hook arrangement is thus converted into forceps, which are normally closed by the spring a, and secure the rider. When, by turning the rod c, the rider is lowered, contact between m and e checks the corresponding motion of the sleeve, thus opening the forceps, and, on continuing the movement, the rider is left hanging free upon the beam. The tension of the spring should be sufficient to close the forceps upon releasing the rod c. If it should be, at any time, desirable to leave the rider upon the beam, all that is necessary to bend its loop as represented in the side sketch, Fig. 2.

Condenser, and Revolving Nessler Stand.—In the condenser adapted by E. W. Martin (Journ. Am. Chem. Soc., xvi., 871), and here illustrated, the three-eighths inch block tin pipe forming the condenser tube is bent in a zigzag shape, as affording a more even flow of the distillate than the conventional helix. The cylindrical copper jacket enclosing it is about fifteen inches long and four inches in diameter, and is closed at both top and bottom with discs that are arched upward. The effect of this at the lower end is to prevent contamination of the distillate with any drip from the outside. To ensure the more certain delivery of the distillate the lower end of the tin tube is cut salant. In the case of water analysis, distillations, etc., a stoppered glass flask with side-neck is used, the end of the latter being bent vertically downward, as shown, and thrust deeply into the condenser tube, being held in position by a short piece of rubber tubing. Martin’s revolving Nessler rack is represented in the same illustration, and, as will be seen, consists simply of two circles of thin board connected by light strips of wood, the upper circle being perforated for eight or ten tubes, and the lower one partly perforated to form shallow sockets. The whole revolves about an upright set in a base, and if one tube in the rack be placed in position to receive the drip from the condenser, the others can be brought successively into the same position, and the order in which the fractions of the distillate are taken is easily preserved.

Balance-Adjusting Device.—Balances used for analytical work are sometimes, and prescription scales generally, lacking in means of adjustment, and to remedy this defect, where it exists, Frank T. Green (Journ. Am. Chem. Soc., xvi., 699) suggests a plan which is extremely simple and does not require special skill in its application. It is assumed that the beam has a centre screw (Fig. 2, A) on top, but if not one can easily be added. The strip of brass (Fig. 1) is fixed beneath this screw in such a manner as to slide either to the right or left as required. When the point of adjustment is reached the brass strip is firmly clamped by means of the centre screw. An alternative plan is to employ an arrow-shaped piece of brass (Fig. 3), which is also fixed by means of the centre screw, the method of adjustment being simply to turn the arrow to the right or left.
Burette Filler, and Nessler Comparator.—In this arrangement for filling burettes, designed by Dr. A. P. Hallock (Journ. Am. Chem. Soc., xvi., 870), a bottle containing at least 2 Lit., is fitted with a rubber cork and a brass collar which carries a burette clamp, the collar and clamp being made of two strips of brass, bent as shown to the left of the illustration, and soldered or riveted together at $\delta$. The ends are turned outwards and fitted with thumbscrews that serve to firmly clamp the circles. To fill the burette a finger is placed on the opening of the short bent tube to the left, and the indiarubber bulb is then squeezed so that the air in the bottle is compressed and the solution forced into the burette by means of the long tube. The latter is kept in position by a cork with a small slot on one side, or fitting loosely in the burette, and the end of it is slightly constricted and cut off at the zero line of the graduation. When the burette is full the air pressure is released by removing the finger from the short tube, and all the liquid above the zero mark then syphons back into the stock bottle. The Nessler comparator, as improved by Hallock, has the form of a large black test-tube rack with ten or twelve holes. A strip of milk glass extends from end to end at the bottom, being held in place by small pieces of indiarubber fastened at each side by small screws, and so close to the base that the glass can just be forced in between. A similar strip of clear glass rests on cleats at the side of the rack, about two inches above the milk glass, being fixed in the same manner as the latter, and upon this clear glass the Nessler tubes stand. The standards are placed in alternate holes in the rack, the intervening spaces serving for the tubes to be compared, which need not be raised in order to make the comparison, whilst the whole apparatus is very readily cleaned and kept in order.

The Pharmacetical Journal
FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, FEBRUARY 2, 1895.

Editorial Department.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to "Street Brothers," 6, Soho Street, Lincoln's Inn, London, W.C., where copies of the Journal may be purchased, and to whom Cheques and money orders should be made payable.

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary—Mr. Richard Brambridge, 17, Bloomsbury Square, London, W.C.

DEATH BY POISON.

The Registrar General's Report for the year 1893 has just been issued, and as usual it contains a mass of detailed information on the subject of poisoning of a fatal nature, both accidental and suicidal. Other forms of death by poison are so few in number that for the purposes of review in this Journal they might almost be overlooked. The cases recorded as referred to manslaughter are five in number. In two of these carbolic acid was the cause of death; in two others deaths are attributed to ptomaines; and in the fifth case death is attributed to a drug used to procure abortion. There is only one case of murder in which poison was the cause of death, and the poison employed is stated to have been prussic acid and oil of bitter almonds.

The number of suicidal deaths by poison were 370, amounting to 14·23 per cent of the total number of recorded deaths by suicide. Out of the whole number in which poison was found to be the cause of death, there were 45 cases in which the nature of the poison is not stated, and 32 cases in which death was caused by one or more of eleven different kinds of poison, most of which are not included in the poison schedule of the Pharmacy Act. There were 128 cases where death was caused by carbolic acid and various acids not in the poison schedule. Of the remaining 165 cases in which death was caused by a scheduled poison, 67 are attributed to opium, morphine, etc., 40 to oxalic acid, 25 to prussic acid, 19 to strychnine, 5 to vermin killers, 5 to arsenic, 2 to mercury bichloride, and 2 to chloroform and chloral.
The number of deaths by poisoning caused accidentally or by negligence were 597, amounting to 3.48 per cent. of the total number of deaths caused by accident or negligence. Of that number the kind of poison causing death is not stated in 23 instances. In 206 instances death was attributed to one or other of thirty-eight poisonous substances not included in the poison schedule of the Pharmacy Act. There were 49 cases in which death is attributed to carbolic acid and various acids not in the poison schedule. This leaves 219 cases of deaths caused by scheduled poisons. Among these, 107 deaths are attributed to opium, morphine, etc., 66 to chloroform, 10 to chloral, 9 to ether and other anaesthetics, 7 to oxalic acid, 7 to strychnine, 6 to prussic acid and potassium cyanide, 4 to arsenic, 3 to ergot, and the remaining 2 to vermin killer and mercuric chloride.

QUESTION AS TO SUGAR IN NORMAL URINE.

The controversy upon this subject promises to become still more interesting. In a letter to the Lancet Sir George Johnson criticises the tests employed by Dr. Pavy to furnish proof that normal urine contains sugar. He refers to the statement of Sir William Roberts that according to his experience urine containing as much as 0.5 per cent. or 2.5 grains of sugar in the ounce gives no sign of the presence of sugar by that test. The formation of crystals in the phenylhydrazine test is also considered by Sir George Johnson to be fallacious evidence of the presence of minute proportions of sugar in urine. Hence he concludes that while the absence of sugar from normal urine has been established by positive and indisputable evidence, the supposed indications of its presence cannot be relied upon. He understands that further experimental results are likely to be produced in support of this view, and in any case, Dr. Pavy may be expected to offer a stout defence of the position he has taken.

THE TREATMENT OF DIPHTHERIA BY ANTITOXIN.

Mr. Lennox Brown gave his final lecture on diphtheria before a very full audience at the Central London Throat, Nose, and Ear Hospital on Tuesday, the 29th ult. Having detailed the treatment until recently pursued, he proceeded to discuss the antitoxin remedy. Stress was laid on two essential conditions for estimating its value; first, that every case so treated should be certified by bacteriological examination to be true diphtheria; and, secondly, that a post-mortem examination should be made in every fatal case so as to ascertain whether there was any truth in the suggestion that the serum treatment is in any degree capable of inflicting harm. In the meantime, taking the figures of one of the Asylums' Board hospitals, he showed that of forty-five cases of true diphtheria treated by antitoxin since the commencement of the year, only two deaths had resulted, as against fifty cases with seventeen deaths in the same hospital in the corresponding period which immediately preceded. This result—which far transcended any previously attained—was due to the circumstance that antitoxin had been used, not as a substitute for, but as supplementary to, the former measures of treatment, especially those of an antiseptic and stimulant character. Mr. Lennox Brown deprecated the teaching that the serum was to be used to the exclusion of all other remedies, on the ground that otherwise its full value could not be accurately estimated; remarking that it was not in consonance with the humane character of the British medical practitioner to make the saving of life in the slightest degree subordinate to a fair trial of a new remedy, and he ventured to prophesy that antitoxin would be acceptable and successful in proportion to its adoption as an auxiliary, and not as a competitor.

DISPENDING APPRENTICES.

Under this heading the British Medical Journal mentions a communication received from a correspondent, stating that he has a message boy who is giving him great satisfaction and would like to be apprenticed to the drug trade. In answer to the question whether, with the qualifications L.R.C.P. and S.E. and L.P.P.S.G., he could take the boy as an apprentice and give him a certificate at the end of his apprenticeship, our contemporary very properly replies that "such an apprenticeship would not confer any special qualification either as chemist or druggist or otherwise."

ARGON.

A large and representative meeting of the Royal Society was held in the hall of the University of London on Thursday afternoon, to hear Lord Rayleigh and Professor Ramsay give the results of their most recent work on the supposed new constituent of the atmosphere. Mr. W. Crookes had also been announced to give a description of the spectrum of the new "element." A full report of the proceedings will be given in next week's Journal, but, meanwhile, it may be as well to recapitulate the information on this interesting subject that has already been published. Lord Rayleigh and his colleague found that when electric sparks were passed through air containing an excess of oxygen, and the resulting nitrous fumes were absorbed by potash, a residue was left which consisted neither of nitrogen nor oxygen, and showed a special line in the spectrum. The gas has since been obtained in quantity by passing nitrogen obtained from air over red-hot magnesium, which gradually absorbs the nitrogen and leaves behind the "argon," which is said to constitute one per cent. of the atmosphere. Its existence, however, is said to be doubted by "orthodox" chemists, between whom and the "spectroscopists" or physicists the issue was raised at the meeting on Thursday.
Indian Medical Congress.

[From our Special Correspondent in Calcutta.]

The first Indian Medical Congress, lately concluded at Calcutta, has been in every respect a brilliant success, having been attended by about 600 medical men from all parts of the empire and from different parts of the world—the total membership having reached close on 900. The only section of special interest to the readers of the Pharmaceutical Journal is that of

Pharmacology and Indigenous Drugs.

The first of the two presidential addresses delivered in this section, was by Dr. George Watt, whose position as Economic Reporter to the Government of India affords him peculiar facilities for the prosecution in the most practical fashion of the Indian Materia Medica, of which, as indicated in his address, there is still a great deal to be learned. He strongly recommended students in this department to turn from books to the bazaars, and showed an interesting collection of drugs which he had lately made in the course of a short tour in the Kangra Valley, purchased chiefly from the native herbalists, and he was not surprised to learn that there were quite a number concerning which even the best informed on these matters were remarkably ignorant.

The most interesting of Dr. Watt's own recent discoveries in this department was a vegetable ferment "Mathoosan" which he had found was sold largely in some parts of Northern India in the form of small cakes, and he was convinced that it would be found very useful in place of yeast in bread-making and in the brewing industry. His suggestion that Himalayan gentian might be much more utilised than it is ought to receive the attention it deserves, especially in India. He advocated Podophyllum emodi once again as worthy of notice on the part of European pharmacognostes, and reminded the section that a research made some years ago showed that the Indian root was rich in podophyllin resin.

Several practical suggestions of great interest were embodied in the address of Dr. Watt's colleague in the Presidentship of the Congress—Rai Bahadur, Dr. Kanny Loll Dey, C.I.E. It will seem inexplicable to many readers that the great Medical Store Departments of India rely but little on the medicinal resources of the country, but the suggested provision of suitable preparations ready for immediate use in the Government hospitals and dispensaries should result in some practical step being taken towards their utilisation. The great obstacle, however, to the more general adoption of the indigenous drugs, in place of medicines at present imported from England, in the great system of charitable medical administration in India, seems to lie in the fact—which was quite overlooked at the Congress—that no study of them is included in the materia medica of the Indian medical schools, which at the best is meagre and limited to the more prominent of the pharmacopeial medicaments.

Dr. Kanny Loll Dey's suggestion that a drug emporium which would be central to the great markets of the world should be established at Calcutta ought to be hailed with satisfaction by all who desire to see the standard of quality of medicines maintained. Cannabis indica grown in the Punjab—to give one important example—has suffered in quality, and consequently in reputation, through the necessity of sending it by rail to the Bombay markets, where it is very frequently mixed with the inferior hemp cultivated in Western India, instead of direct from the hills to Calcutta, where at present there is no proper mart for drugs on a commercial scale.

Dr. Dey's recommendations of drugs deserving of inclusion in the proposed Imperial Pharmacopoeia will be regarded as of some importance, coming as they do from an Honorary Member of the Pharmaceutical Society, and one who has made a study of Indian pharmacognosy for forty years. The herb Adhatoda zavirs has a popular reputation all over India as an expectorant, and is deserving of more attention. The comparatively recent experience of the decided efficacy of the "Krest" (Adropogon paniculatus) in influenza may add weight to the recommendation for its being made official. The "Mudar" leaves and fresh plant of Calotropis gigantea—was the subject of a special paper (by Dr. John Morton, Mussoorie) in the Indigenous Drugs section. It has vesicant properties and is being advocated as a remedy for eczema, of which some remarkable cures were recorded. It obviously requires further trial. The Curica papaya, or, at least, papain, has now been perhaps sufficiently long before the world to justify its claim to official recognition. The undoubted efficacy of the "Kurchi" (bark of Holarrhena antidysenterica) was recorded in the Pharmaceutical Journal some time ago by Mr. Thomas Stephenson. It is now being so much adulterated by the unscrupulous natives, that it stands in some danger of losing its reputation unless some official standard is indicated. The properties of the "gurgun" and "chaulmugra" oils, also included in the Congress recommendations, are now fairly well known. The fact that Dr. Kanny Loll Dey is preparing a new edition of his work on the 'Indigenous Drugs of India,' which is likely to embody the results of his extensive researches in this department, was recently referred to.

The other papers read in the Indigenous Drugs section were not productive of any very new facts in materia medica. The popular belief in the high antipyretic value of quinine was questioned by Surgeon-General Sir William Moore. In another paper by Surgeon Liet.-Colonel F. V. Jenison, the hypodermic treatment of malaria was advocated in doses of half a grain of the neutral sulphate dissolved in water. Permanganate of potash solution was recommended in another communication as an effective preventive of danger from bites of rabid animals, the deaths from which number in India 80 or 90 per cent. of those bitten. The Eastern panaceas, "Vapor Opti," was held by Dr. Cama of Bombay as worthy of adoption among the official vapours.

The presence and enthusiastic co-operation with the local committee of Mr. Ernest Hart, as delegate of the British Medical Association, added very
materially to the success of the Congress, and be delivered several most important addresses during his sojourn in Calcutta. In the course of an exhaustive review of the position of the medical profession in India, he laid great stress on the importance of scientific and practical work in bacteriology and micro-pathology. He revealed the fact that the great majority of the 10,000 medical men of India were about ten years behind the times in this respect. He advocated the establishment of research laboratories and the prosecution of preventive medicine and improved sanitation, and his recommendations have been submitted to the Government of India by influential sponsors. It was significant that the leaders of the Congress were inclined to favour such advanced medical conceptions as the antitoxin treatment of diphtheria, anti-choleraic inoculations, and the Pasteur system generally.

In the section of Medico-legal Medicine the Chemical Examiners to the Government for Bengal made a strong representation, which will be transmitted to Government, urging the necessity for restriction in the sale of poisons in India, particularly with regard to the sale of opium and arsenic. It is well known that the most dangerous poisons may be purchased with impunity in all the native bazaars.

A small but very successful EXHIBITION of medical and pharmaceutical specialties was held while the Congress lasted. The principal exhibitors were Messrs. Burroughs, Wellcome and Co., Messrs. Allen and Hanbury, Messrs. Smith, Stanistreet and Co., Calcutta, and the Mellin's Food Company for India, Limited. The next Indian Medical Congress will probably be held at Bombay in the "cold weather" of 1898.

Proceedings of Societies in London.

ROYAL INSTITUTION.

On Tuesday, January 29, Professor Stewart delivered his third lecture on the internal framework of plants and animals. After recapitulating the structure of Actinophorium and Acanthometrium, he proceeded to describe a variation from the latter in which the capsule enclosing the central protoplasmic mass is provided with one aperture only, whilst numerous solid siliceous rods, often armed with spines, lend support and perform other functions, in addition to which the creature is furnished with pseudopodia. In another form a network of filaments distributed in layers through its whole substance affords efficient support; in this case swimming movements are effected by a flagellum. A number of such units sometimes aggregate to form a colony, examples of which can be found in Spherosoma. In one of these a central mass of vaculated protoplasm is surrounded by groups of denser nucleolated protoplasm, each of which is encrusted by spicules.

Under the name Metasoma were grouped those forms of life in which the egg-cell divides and gives rise to a number of others which fulfil different functions. Some form a skin, some an internal lining, others again a middle layer performing the function of muscles.

Professor Stewart then proceeded to deal with the sponges, showing that between the outer layer of cells or ectoderm and inner lining or endoderm there is a middle layer or mesoderm; one of the chief constituents of which is a jelly-like substance or mesogloea. Certain of the cells of the endoderm assume a rounded instead of flattened form, and develop cillie by the action of which a current of water is drawn through the small pores and ejected through the large ones. Certain of the cells of the ectoderm appear to migrate into the mesogloea; from some of them proceed filaments which protrude between the cells of the ectoderm, the latter also sending accompanying threads. Such filaments may be regarded as a very rudimentary sensory apparatus; change in the environment is frequently followed by movements of the sponge mass, closing of the pores, etc., the impulse being apparently communicated through these projecting filaments. Other cells that have migrated into the mesogloea produce calcareous or siliceous rods.

Professor Stewart afterwards described the structure of Granitio compressa and explained the means by which a current of water could circulate through it, as well as the form and nature of the spicules, and the manner in which they acted as a support. Venus's flower-basket (Euplectella) was dealt with in a similar manner, particular attention being drawn to the means by which the spicules were cemented together.

Amongst the objects exhibited under the microscope were specimens of horny sponge (Chalinia), siliceous sponge (Meyeriina), spicules of Laboria, and Sphero-soma, calcareous sponge (Granitio compressa), Euplectella, and a horny sponge (Stonchophyllum), in which dead shells of Radiolaria formed part of the skeleton.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At the meeting held on Thursday, January 24, the following paper was read:—

VOLUMETRIC AND COLORIMETRIC ANALYSIS.

BY W. H. SYMONS, F.L.C.

Sutton defines volumetric analysis as "quantitative chemical analysis by measure," and he says "it depends upon the following conditions for its successful practice:—

"1. A solution of the re-agent or test, the chemical power of which is accurately known, called the 'standard solution.'

"2. A graduated vessel from which portions off may be accurately delivered, called the 'burette.'

"3. The decomposition produced by the test solution with any given substance must, either in itself or by an indicator, be such that its termination is unmistakable to the eye, and thereby the quantity of the substance with which it has combined accurately calculated."

I shall accept this definition and these conditions, and shall also deem it quite unnecessary to point out the advantages which volumetric methods possess over gravimetric in certain cases, for we are all convinced of the extreme accuracy, rapidity, and sim-
plicity of the operations required. Neither shall I bring forward any new methods, but I shall content myself by enlarging upon the conditions necessary for the successful practice of every-day operations, and I shall follow the order in which these have already been stated, viz., Standard Solutions, Appliances used in Volumetric Analysis, and End Reactions.

Standard solutions.—Standard solutions in the common and loose acceptance of the term are really standardised solutions, and not necessarily solutions of standard strength. Sutton in his 'Volumetric Analysis' recommends "that no attempt should be made to attain rigidly exact standard solutions, but that their strength should be accurately ascertained and the necessary factors marked upon the bottles in which they are kept. Thus he writes, "Suppose that the acid is too strong, and that 33.2 Cc. were required instead of 35.85, 35.2 — 1.0184 ; 1.0184 is therefore the factor by which it is necessary to multiply the number of C.c. of that particular acid in order to bring it to normal strength. This plan is much better than dodging about with additions of water or acid."

"Under all circumstances it is safer to prove the strength of any standard solution by experiment, even though its constitution has been accurately weighed in the dry and pure state."

Now, personally, I prefer to use in all cases when dealing with an unalterable substance a rigidly exact standard solution; it saves so much time in calculation and is otherwise much more satisfactory, and I fail to see any necessity for dodging about. What can be easier, for example, in the case quoted than to make 1000 C.c. of the solution up to 10184 C.c. with water and so make the solution strictly comparable with any other of normal strength? These measurements can with care be done to 0.05 C.c., and hence the error with two measurements need not exceed 1 in 10,000. I am going to try to demonstrate this to you by mixing a litre of normal acid with a litre of normal alkali, and, adding methyl-orange, seeing how much of a deci-normal solution is required to restore neutrality. Now these solutions were not made as laboratory experiments but for every-day work in a factory. I should make no special virtue of this if I did not know that in many cases chemists were satisfied with a much lower standard, and that solutions are sometimes sold as standard solutions which vary as much as 1 per cent. from normal. I may be asked what is the use of making solutions to agree so nearly one to the other when the absolute value of either cannot be ascertained with anything like the same degree of accuracy, and when even an error of one per thousand may be usually disregarded?

I reply that errors easily become multiple. Thus, in determining ammonium carbonate, two errors in weighing and four in titrating, if all the same way, might mean an error of 0.5 per cent., or, if the 1 per cent. standard were adopted, of no less than 5 per cent. The knowledge that in titrating one solution with another no appreciable error is introduced by variance of the solutions is worth far more than the little care it takes to measure accurately and adjust in

the first instance. The secret of success really consists in measuring quantities of liquid accurately by using narrow-necked flasks and pipettes for measuring in place of the official cylinder, and in working on fairly large volumes of liquid when titrating. We get the same error in measuring 5 C.c. as in measuring 50 C.c., being open to an error of 0.1 C.c. in reading the burette; this alone in the former case means no less than 2 per cent., whereas in the latter case it is only 0.2 per cent.

Furthermore, I do not think that much good is done in attempting to standardise the solution of any substance which can be obtained in a dry and pure state, for example, silver nitrate. It is difficult to imagine any substance purer than pure silver nitrate, and in making its volumetric solution all that is necessary is to weigh and measure accurately.

I shall this evening frequently use the word normal as indicating the strength of a solution; one would think that with a word in such common use there could be no ambiguity, but, unfortunately, in pharmaceutical circles such ambiguity does exist. Sutton is very clear, and says "Normal solutions as originally devised are prepared so that one litre at 18° C. shall contain the hydrogen equivalent of the active re-agent weighed in grammes (H = 1)," and as far as my experience goes, it is in this sense that the word normal, as regards volumetric solutions, is commonly applied, but on turning to 'Attfield's Chemistry,' we find "Normal solutions contain one molecular weight of substance in grammes per litre," and no mention is made of any different opinion being held. Many text books contain similar teaching. This is most unfortunate. Semi-normal, quinti-normal, and deci-normal are also common terms for the weaker solutions, dt-normal is used for solutions of double normal strength, and I have proposed the terms penta-normal and deka-normal for stronger solutions which serve as common re-agents. I find it a great advantage to keep solutions of equivalent values rather than on the percentage system.

Appliances used in volumetric analysis. Most important among these are measures, and here we are at once met with a difficulty as to what we mean by a cubic centimetre. Do we mean the volume of a gramme of water at its greatest density, or do we mean something else?

Freseniuus advocates the use of the true cubic centimetre. Mohr takes the C.C. as the volume of a gramme of water at 17° 5, which makes his litre flask hold 1.2 C.C. more than the strict litre. Sutton advises the use as the C.C. of the volume of one gramme of water weighed at 16° C. really 0.999 C.C., his reasons being the difficulty of reducing the temperature to 4° C. and the number of wrongly graduated instruments in use.

I prefer to use the strict cubic centimetre and do not see the necessity of cooling to 4° C. If we know the specific gravity of the water at the temperature at which we weigh, and this has been accurately determined by Despretz and others.

A cubic centimetre of water at 16° C. (58°.06F.) weighs 0.99898 gramme, and at 15° C. (59°F.), which in
many books on physics is taken as the standard temperature, 0.999125 grammes.

For everyday purposes the P.B. temperature, 15° C. (59° F.), may be taken, and the specific gravity of water as 999.05. If it is wished to standardise a flask, it should be weighed when quite dry, then 999.05 grammes of water introduced, taking care not to wet the upper part of the neck of the flask. When the temperature has been adjusted to 15° C., this weight of water will be exactly one litre, and the mark opposite the bottom of the meniscus of the liquid will be the fiducial mark. The flask should then be emptied, drained for thirty seconds, and again weighed. This will give the weight of the residuum and enable us to calculate the mark on the neck, to which it will be necessary to fill the flask when it is required to deliver one litre.

The result of six weighings by Mr. Stephens and myself will show what accuracy may be expected:—0.90, 0.98, 0.85, 0.92, 0.83, 0.89, giving as a mean 0.9 and a variation of less than 0.10 C.c. Of course the residuum will vary with every liquid. Thus with strong hydrochloric acid Mr. Stephens obtained a mean 1.10 C.c. The liter flask should have, in addition to the supposed fiducial mark, graduations above and below in terms of 0.10 C.c.; these may conveniently extend down to 998 and up to 1010 C.c. or more, and will be found extremely useful in many ways. I have had my flasks pipettes, and specific gravity bottles so marked with millimetre divisions for the last fifteen years.

Pipettes are the most accurate form of measures of capacity. They are bulbcd and graduated to deliver or contain fixed volumes, or they are cylindrical and graduated to deliver various volumes at the discretion of the operator. The former if used as containing so much, i.e., if rinsed out with the solution of the substance, then filled up to the fiducial mark with the solution of known temperature, and washed out with distilled water, the washings being added to the solution, are instruments of extreme precision and rival the balance in accuracy. If used to deliver certain quantities they are not quite so accurate, and their shape becomes a matter of some importance. They must always be emptied in the same way and drained for a definite time. It is a good plan to allow them to drain for half a minute, holding the bulb in the closed hand, and finally touching the sides of the vessel with the delivery point, but not blowing the residual liquid from them. That form made with a tube of some length below the bulb are convenient for taking liquids from bottles, but do not deliver so well.

We are now able to obtain burettes and pipettes guaranteed as “normal” by the German Physical Society. I have carefully examined one of these burettes and can find no error in it. Mr. Stephens has also thoroughly tested a complete set of “normal pipettes,” varying in capacity from 2 C.c. to 100 C.c., and in no case was any error found. Any one who has been in the habit of standardising the instruments as purchased will know what an immense improvement this is.

Floats.—There can be no doubt that the use of proper floats increases the accuracy of reading the quantity of fluid delivered by a burette, and Fresenius says that by their use we may read to 0.02 C.c. This may be possible to an expert, but I am persuaded that, as commonly used, floats are a source of error rather than an aid to accuracy. They are usually much too large for the burette. Several other devices are in common use, such as a thick straight line behind the burette, but these devices are accessories, the value of which one must personally determine for oneself. The limit of accuracy being the size of the drop of the liquid, I think it is far better to trust to reading from the bottom of the meniscus, taking care when exact results are needed to use so much substance that nearly a buretteful of volumetric solution will be needed to bring about the end reaction.

Store Bottles for Volumetric Solutions.—Where a large number of analyses have to be made, nothing can be more satisfactory than the time-honoured aspirator; when analyses are less frequently but regu-

---

STORE BOTTLE—1/4 ACTUAL SIZE.

larly called for, then a store bottle, forming the foot of the burette stand, from which the solution may be blown into the burette is extremely useful, whereas, for a single series of analyses an ordinary wash bottle about 150 C.c. capacity may be filled with the solution which may be blown into the burette, or the bottle being attached to a strong test tube, may be placed above the burette as shown in the illustration, the T-piece and two taps being as usual.

Jena Glass.—Germany has conferred another great boon on the world by giving us a nearly insoluble glass.
Its more general introduction is likely to mark a distinct epoch in water analysis. Water standing for a few days in ordinary blue-stoppered Winchesters becomes contaminated with silica to a notable amount, and as the difference of a few tenths of a grain of silica per gallon may have considerable influence on the action of the water on load, this matter is of great importance. The analytical data as to the amount of silica in many natural waters will probably need correction. For so far waters for analysis have invariably been collected in vessels capable of yielding from one to two grains per gallon of soluble substance, and re-agents have also been stored in vessels of similar material. In quite the early days of chemistry this was recognised, and glass vessels were discarded in prolonged operations, and especially where water had to be concentrated.

Jena glass does not yield a tenth of a grain of solid substance to a gallon of distilled water, even when this is evaporated to a small bulk in the vessel. Jena glass flasks are, therefore very useful for evaporating large volumes of water, and Jena glass tubes for condensing distilled water.

I have asked the makers to supply me with stoppered flasks, or Winchesters, so that waters for analysis may be collected in them, but although I made the request early last year, I have been unable to obtain them from Germany; Messrs. Gallen kamp and Co., however, have been kind enough to have those on the table specially ground for me in England.

(To be continued.)

\[\text{MANCHESTER PHARMACEUTICAL ASSOCIATION.}\]

\text{ADDRESS BY MR. MICHAEL CARTEIGHE.}\n
A meeting of the members of the Manchester Pharmaceutical Association was held on Wednesday week at the Albert Memorial Hall, Manchester, to hear an address from Mr. M. Carteighe, President of the Pharmaceutical Society of Great Britain. There was a large attendance. Mr. G. S. Woolley, President of the Manchester Society, was in the chair, and with him on the platform, besides Mr. Carteighe, were Messrs. G. S. Westmacott, W. Bowden, F. B. Benger, J. R. Young, W. Wilkinson, W. Kirkby, A. J. Pidd, and H. Kempt (Secretary).

\text{THE CHAIRMAN, opening the proceedings, said the Council of the Manchester Pharmaceutical Association could not allow the opportunity afforded by the visit of the President of the Pharmaceutical Society of Great Britain to Manchester to pass without inviting him to meet the members, in order that they might hear from him words of advice and encouragement. The Council was quite alive to the importance of swelling themselves of every opportunity of enabling the members to make the personal acquaintance of their leaders, and of those leaders there was none more capable and fitted to speak to them on trade politics than Mr. Carteighe. No leader had devoted a larger share of the best years of his life to the furtherance of their interests. Since Mr. Carteighe last addressed them in Manchester, Mr. Woolley continued, he had noticed an increased amount of interest taken by the members of the district in pharmaceutical politics, and he was not without hope that the remarks of that day would tend to increase the interest. Mr. Carteighe had promised to speak on the things that it was possible to attain in the way of pharmacy legislation, and might refer to the way in which the Manchester district could assist the efforts being made to improve the legislation which governed their trade.}\n
\text{Mr. Carteighe said it was a special privilege to be allowed to address a Manchester audience once more. He remembered that, as a result of some observations which he made in Manchester three or four years ago, and of the discussion that ensued, several men who had felt themselves antagonistic to the Pharmaceutical Society had joined it and become useful members. He was glad to hear of the increased activity locally. Obviously it was one of his duties, as President, to bring himself and the Council as much as possible in touch with every part of the country. The Pharmaceutical Society was not a London association. It was a corporate body representing Great Britain in its entirety, and there should be an endeavour, as far as practicable, to unite the wishes of those in the north with those in the south.}\n
\text{Coming to a consideration of the questions, "What is it we want?'' or "What do we think we want?'' he thought they must all feel, having regard to their education and training (though some of them thought that was not so effectual as it should be), that they were entitled to ask, and he thought the public was entitled to ask, that the compounding of prescriptions, and not simply the compounding of poisons, should be left in the hands of registered chemists and druggists. There were some who thought that the sale of all preparations compounded in the pharmacy should be so limited, and he was distinctly of that opinion himself. But he could not help feeling that in this free trade country, where legislation was much more difficult to accomplish than it was in a new country, or even in Ireland, it was desirable that they should proceed step by step instead of trying to get to the top of the ladder all at once by means of a rope. The chances were that if they were too precipitate they would lose some of the privileges they already possessed. The Council had been obliged to carry out the Act of Parliament during the last few years in a manner which some persons—not on the Register of Chemists and Druggists—considered rather drastic. The Council had to take many proceedings at law, and the meeting would readily understand that a certain section of the community, whether called the grocer section or the huckster section, would not be particularly anxious to increase the powers of pharmacists. They would have to consider how far they could overcome the opposition of those who, like themselves, had votes and influence in the House of Commons. In Ireland, the compounding of prescriptions was restricted to registered men, and it was fair and reason}
able to ask Parliament to make a similar restriction in Great Britain. He believed this would have been granted years ago if it had not been for the unfortunate differences that existed between the Pharmaceutical Society on the one hand and those not connected with that body. Originally, the Pharmaceutical Society never intended to go to Parliament for a Poisons Bill. Its intention was to go for the restriction of the compounding of medicines, and it was want of sympathy very largely, and differences of opinion upon what were, after all, minor matters, that prevented the draft Bill of 1886 being carried into law. All they could do in the future was to amend the Act they had on safe lines. Whatever their condition was in 1886, they could claim now that they had in every district a class of men fully competent to dispense every prescription that any medical man could write. He had grave doubts whether in 1886 that was the case. In outlying parts of the country, where dispensing was done by general practitioners, very many chemists had not had much experience in dispensing at that time. Now they had a special claim on the Legislature, as much as the Society had created a class of young educated men, spread throughout the country, who were ready at a moment’s notice, when doctors would give up dispensing, to do it—should he say as well—perhaps he ought to say much better than the doctors did it themselves.

The question of company trading had not been lost sight of, and could not, of course, be overlooked. They must remember that the judges had held that a corporation was not a person, and that corporations were not provided for in the Pharmacy Act, and were not within it. As President he had to make himself more or less disagreeable by pointing out that this judgment was due to the fact that in the Pharmacy Act they had inserted a special clause, which differed in principle from every other part of the Act. It began by asserting the necessity—for the safety of the public—that every person who dispensed poisons, etc., should be qualified and registered, and then immediately set to work to undo that by saying that in the event of the death of a registered person, the qualification which was vested in his person should pass to executors, or his widow and children, providing a registered assistant was kept. The insertion of that clause was a grave mistake. He and another member of the Council tried to exclude it from the draft Bill, but were unsuccessful. The Bill created on the one hand a sort of statutory professional title, which was to be purely personal in its character, and, on the other hand, tackled on to it something which simply applied to the conduct of a mere business which went like machinery. If chemists and druggists really believed that it was right and proper that their widows, administrators, or executors should have power to carry on business in the way now provided, it was hopeless and illogical to ask any Legislature to deal with company trading. At the time of the passing of the Act it was said that time must be allowed for the estate of a deceased chemist and druggist to be wound up, and that during the short period allowed, the danger to the public would be limited to a year, or a few months at the outside. Trusts went on for very long times, and it was possible to obtain all the personal privileges conferred upon them individually by the Pharmacy Act of 1888, as readily through the executors’ clause as by the provisions of the Companies Acts. The position of chemists and druggists would be assailable always as long as that clause remained. He was not prepared to say that even if the company question had not been settled in the way it was, means would not have been found, through the executors’ clause, of carrying on the business of chemists and druggists by registered persons. There never was a law through which a coach and four could not be passed. It was true there was one considerable difference between the position of a company and the position of executors. The Council of the Pharmaceutical Society could sue the latter if they did not keep a registered assistant, but could not sue a company. What the Council had to do, therefore, was to sue any unregistered person in the employ of a company who actually handed over poisons. It had been very successful in many cases where a man who owned nearly all the shares was carrying on the business; it had recovered several penalties, and produced a salutary effect. It would be open to the members of the Society to say whether they thought companies should be made liable for the acts of their assistants, and whether they would do anything that would tend to legalise company trading so long as the company employed registered persons. Hitherto the Council had refrained from doing anything in that direction. After further arguments on the same subject, Mr. Cartiege stated that the loophole given to companies by the executors’ clause was a difficulty which must be faced before the Council could draft any clause dealing with the companies.

He next spoke of the question of erasing from the Register the names of persons who had been guilty of offences, stating that it was very important that the Council of the Pharmaceutical Society—of course, with the approval of the Privy Council—should have this power. He was not suggesting a code of ethics, because under present conditions, and taking into account the battle everyone—principal and assistant—had to engage in to earn his bread and butter, it would be an extremely improper and dangerous thing to have powers of that kind. He did not suggest that a man who had been employed at a store or by a company should be struck off on that account. He would like co-operation among them all to bring them all to a higher state without the pressure of the law. But when a man had committed a misdemeanour he should be erased from the Register, as lawyers and doctors were erased from their registers, or they could not, as a body, claim from the public that consideration and respect which they had a right to demand. A person struck off, however, should have the right of appeal for reinstatement after a certain number of years.

With regard to educational matters and examination matters, he should like to see—and he thought hi
brethren in the trade were beginning to realize its necessity—a preliminary examination imposed upon all who wanted to enter their craft, the examination to take place when the candidates were 16 or 17 years of age. Then they wanted what had been recently obtained in Barbados, the provision of an intermediate examination not less than a year after the preliminary, and a final examination when the pupil became 21. He considered also that three years' service of some kind, using the word service under the old conditions, was part of a proper training, course of instruction—which an employer could not give—going on at the same time. Under this system there was an advantage to those who were already in the trade. They did not reject the competent; the incompetent they did not want. Some of the candidates who came before examiners were nearly 40. They never passed, and how did they earn their living? By poaching upon the craft into which they could not legally enter. If they gave their young men a proper and a distinct course of training, he hoped and believed that 95 per cent of them would pass, instead of about 40 per cent. When that could be done, every chemist and druggist in business would be a financial gainer. To encourage a lad who had been picked up in the street, taken into a pharmacy, and engaged as bottle-washer for three or four years, to try and get into an occupation for which his education did not fit him was not only bad for the trade, but a delusion to the lad. An uneducated person who by a fluke succeeded in passing the examination could not succeed in business in these days.

He confessed he was one of those who believed, when the Pharmacy Act was passing through Parliament, that most of the young men who would go in for the higher qualification—would equip themselves for the Major examination. He regretted to say that he had been grievously disappointed. All over the country, and especially in Scotland, which was supposed to be a specially educated place, a relatively small number of men went in for the higher examination. He could assure all those young persons who might read his observations, that, in his belief, just as it paid to be trained for the Minor examination, so it would pay to be trained for the Major, but the Council of the Pharmaceutical Society could not compel students to enter for the Major examination, and it did not wish to use compulsion.

It remained for the Council to deal with that class of men who might be said to be the backbone of any business or profession—the men who were not specially learned, but who were learned enough to ensure the safety of the public, and many of them better men than some pharmaceutical chemists in certain respects. Those men were asked to join the body politic, and they were asked, in the exercise of their voting powers, to have some sympathy, and—if even there should be a divergence of opinion between the pharmaceutical chemist members and the chemist and druggist members—to leave something for the sake of "Auld Lang Syne" for the former. This change having come about it must be faced and dealt with. The Council of the Society was quite willing to go to Parliament for a short Bill, with the hope that it would be non-contentious, for the purpose of altering the constitution of the Council and making more chemist and druggist members eligible for election thereto.

Proceeding, Mr. Carteigh said the title of his observations was "The Possibilities of Legislation." He had mentioned at considerable length the legislative wants of chemists and druggists, but it might be said to him, "You have not been able to point out all the remedies. You have not been able to tell us how we are going to get all these wrongs redressed."

He confessed that he had not. Until the President of the Pharmaceutical Society had at his back a majority of the chemists of the country, until he and his colleagues could go to the House of Commons with that statement, he had grave doubts whether they would get anything. If, therefore, they meant business in Manchester and elsewhere, they should begin at once to consider that point and to rally round the Pharmaceutical Society. Let them not criticise what was done in the past, many of them did not know the reasons why certain things were done. He could talk for a week giving very good reasons for many things that must appear somewhat absurd. They had to deal with the subjects of to-day, and if they were to succeed, the Society must have all or a great majority throughout the country at its back. More than that, chemists must begin to do as other bodies did; they must consider the interests of their craft in connection with the great political interests of the country. They ran a risk of being squeezed out entirely if they did not make some terms with their representatives. He had tried to dissuade himself from the notion, but he was not quite sure that they would not be driven, by the force of circumstances, to consider at the election of every member of Parliament, in every constituency, the question how far those candidates should be questioned in regard to matters pharmaceutical. Members of Parliament wanted educating, and governments required educating. Since he was a boy they had been dealing with measures, some of them, no doubt, of extreme importance, and not a few of them—if he might say so, with all respect to their august chiefs—not a few of them largely sentimental.

As for domestic legislation in its widest sense—legislation affecting the great masses of the people—governments had not done a single thing, except when the classes had driven them to do it. Therefore they should consider whether they should not adopt, at the next general election, in a proper and a deferential way, some sort of proceeding which would serve as an object lesson to all the candidates. Candidates should be shown that there was a class of men throughout the country, fairly well educated and some of them influential, who were called chemists and druggists, and that they had a claim to consideration at one time or another. Personally, he should make it very uncomfortable for one candidate who had obstructed them, unless, when he had been educated—and his education should not take more than five minutes—became
to a right frame of mind. The Pharmaceutical Society was powerful for defence; it would undertake to stop measures that would do them harm, but was hardly inclusive enough or influential enough to put pressure on governments to take up its measures, and never would be until the Council had the great majority of the trade at its back working in one direction. He did hope that what he had said might be the means of stirring some enthusiasm among those who had not hitherto considered it a part of their life to consider these matters. Chemists and druggists were a product of true technical education which everybody was concerned in, and there was no better time to talk to members of Parliament of the desirability of certain privileges being given to a class of technically educated men, not wholly for their own personal gain, though that must be considered, but because such a policy would conduce to the welfare and the safety of the community.

The Chairman proposed, "That the Pharmaceutical Society is deserving of the support of the trade in its efforts to carry out the existing laws and to promote further legislation." He remarked that so long as it could be said that only one-fourth of the members of the trade belonged to the Society so long they had a very difficult question to answer. As regarded enrolling chemists and druggists who had commenced business since the passing of the Act of 1868 as members of the Pharmaceutical Society, he for one would be strongly in favour of the passing of an Act that would confer that privilege on the trade, and he should be strongly in favour of allowing the trade to elect any proportion of such members that they thought fit on the Council of the Society. The "Widows' Clause," in his opinion, had been largely instrumental in making poor widows. When consulted he had always advised widows to sell their business, and when this advice had been disregarded it had ended in disaster nine times out of ten.

Mr. Taylor (Bolton) seconded the motion. It was a surprise to him, he said, not that so few young men went in for the Major examination, but that so many did so. All the privileges of the trade were granted to those who passed the Minor examination, and why then should they submit themselves to a further examination? As to the "Widows' Clause," one of the leading trade journals had said that the majority of chemists and druggists were in favour of maintaining that clause, but he disagreed with that opinion, and he was strengthened in his disagreement by an editorial admission that most of the letters which that journal received were in favour of abolition. He would be bound to say there were not ten widows and executors carrying on businesses in Lancashire, and there was no doubt that the best thing a widow could do, in the majority of cases, was to sell the business as quickly as she could. As regarded company trading, he should never be satisfied until the Council had introduced a Bill aimed directly at this method of business. Such a Bill simple justice demanded. The law said, "No man shall be allowed to carry on the business of a chemist and druggist unless he is registered," and then it said that seven men, banded together, could become chemists and druggists. The only way to arouse public opinion on the question was by an Act of Parliament, and he agreed that it was of little use striving for anything unless the trade could present a united front.

Mr. H. Kemp, speaking in support of the motion, said they ought to strive for the exclusive right of compounding medicines as well as compounding poisons. The public health was as much endangered by the unskilful dispensing of medicines, non-poisonous in the ordinary sense of the word, as by the dispensing of poisons. The public needed more protection from the incompetent dispenser. He quite agreed with the president that the "Widows' Clause" should be removed or remedied. He did not say for one minute that a man's establishment should be closed the day he died. A reasonable limit—two or three months or more—should be put upon the time during which a business could be carried on by executors. And the Council should have power to extend the time where they thought it desirable. He also believed that it was disastrous in most cases for a widow to carry on business, but to force a sale immediately after a man's decease was a very much greater disaster. At the same time, he could not accept Mr. Taylor's estimate of the number of widows and executors who carried on business in Lancashire. He knew more than ten in Manchester alone. One reform which he should like to see was compulsory notification of changes of address of chemists and druggists who were on the Register. That matter should not be left to Local Secretaries. Under the present system, men who were dead or who had removed to other parts of the world might be allowed to remain on the Register for ten, twelve, or fifteen years, and that led to deception, and to trouble in the identification of those who were covering or assisting to cover bogus companies. He knew a man on the Register who gave as his address the addresses of a bogus company which he was covering, and never mentioned the address at which he really carried on business on his own account. Concluding, Mr. Kemp said the Pharmaceutical Society was deserving of much more support than it secured. They wanted all chemists and druggists to join, not only because they paid a humble subscription, but because their moral support was valuable.

Mr. Saunders said it seemed singular to him that chemists and druggists should have to submit to all this legislation in reference to the dispensing of poisons. The system made fish of one and flesh of another. Why should medical men be exempt from provisions by which chemists and druggists were bound, hampered, fastened and tied as if they were children? Much more poisonous matter came out of surgeries every day than came out of chemists' shops, and it was only regulated by rule of thumb. He knew the trade before the Pharmacy Act was passed, and it was five times as good then as it was now. The Act had been the ruination of the trade. What did chemists want with regulations when medical men were free?
Mr. Carterhe said it was true that a medical man could dispense any medicine he chose in his private establishment, but he was liable under some of the provisions of the Act. It was also true that a medical man could not be compelled to keep a registered person to dispense his medicines, and he had heard that in many surgeries the dispensing was not as it should be. He would remind Mr. Saunders that the Act was passed to provide that persons keeping open shop for the sale of certain things should be registered. When a doctor kept open shop, the conditions under which that doctor had to carry out his selling and dispensing were precisely the same as the conditions under which the registered chemist and druggist carried on business. They might think it undesirable that medical men should dispense their own prescriptions, but it was not the best way to get that branch of dispensing into their hands to abuse many men who were quite as hard worked as they were themselves.

The resolution was carried with but two dissentients.

Mr. Kirkby proposed "That this meeting, while acknowledging the efforts of the Council to consolidate the Pharmaceutical Society, thinks that end will be greatly furthered by the removal of the limit as to the number of chemist and druggist members upon the Council."

Mr. J. R. Young (Warrington) seconded the motion, which was supported by Mr. Phillips and carried unanimously.

The thanks of the meeting were voted to Mr. Carterhe on the motion of Mr. Kemp, seconded by Mr. Wilkinson, and the proceedings then ended.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The annual meeting of this Association was held on January 21 at University College, Mr. Berry (President) in the chair.

The Honorary Secretary (Mr. Keen) read the report of the Council for the year 1894 as follows:—The number of members constituting the Association continues nearly the same as it has been for the last five years; and the property of the Association, that is its library and its collection of materia medica, is now housed and cared for in the buildings of the College. A general desire having been expressed for the promotion of some systematic teaching in the subjects of materia medica and pharmacy, in addition to those of chemistry and botany, which are well provided at University College, the matter was carefully discussed by the Council, and it was finally determined to accept a very kind offer on the part of Mr. Keen, pharmaceutical chemist, to make the experiment for one session of holding a weekly class for "Readings and Illustrations of the Pharmacy and Materia Medica of the Pharmacopoeia." A fee of 7s. 6d. was to be required from each student towards the expenses of the course, but Mr. Keen declined to receive any remuneration for his work. Arrangements were fortunately made with the Council of University College, who very kindly allowed the use of a room for those meetings, and Messrs. White and Towzersey (Gilles, Schacht and Co.) had been good enough to allow the class to meet occasionally in their laboratory and witness processes of pharmaceutical interest. The experiment has been distinctly successful, and the students attending were showing satisfactory appreciation of what was offered them. The demand for the books of the Library continued to be fairly good; a few of the books had had to be re-bound, and the collection of materia medica was being turned to good account by Mr. Keen.

The statement of accounts submitted by the Treasurer (Mr. Stroud) showed a balance in hand of £9 14s.

"The Chairman, in submitting the proposition, "that the report and statement of accounts be received and adopted," referred to the satisfaction all present must have felt at hearing that Mr. Keen's kind and generous offer was being so well appreciated. He had long hoped for a complete School of Pharmacy in Bristol where apprentices and assistants might qualify themselves in full for the examination room without the intermediate London crammer, and he still continued to indulge that hope. Perhaps, however, the obtaining of a compulsory curriculum was a first step, then a well-organised scheme of instruction would become a comparatively easy matter, but that time had not yet come. In the meanwhile they felt very grateful to Mr. Keen for so kindly volunteering to fill that most conspicuous void. Young pharmacists could get very good systematic teaching in both chemistry and botany at the courses of lectures at the University College, and elsewhere, but in mat. med. and pharmacy there was no teaching to be had except at the Medical School, and that was scarcely of the kind pharmacists required, therefore Mr. Keen's offer was of great value, and he hoped sincerely that the experiment, as he termed his labours, would be thoroughly satisfactory and lead to something perhaps still more complete. He thought that upon the whole the Association was doing some good work, though undoubtedly with a little more enthusiasm they might do better.

The proposition of the Chairman was seconded by Mr. Chandler and carried. The new Council was then elected, and the officers appointed Mr. Allen, President; Mr. Stroud, Vice-President and Treasurer; Mr. Keen, Hon. Sec.; Messrs. Berry Chandler, Pitchford, Plumley, Richards, Sechacht Towzersey, Warren, and White.

Scottish Transactions.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.

At the meeting on January 24, Mr. John Foster, vice-president in the chair, a most pleasant and profitable night was passed with Mr. J. Rutherford Hill, who brought with him an interesting collection of specimens, mostly related to the vegetable kingdom and materia medica, which he gave short accounts of.

Cinnamomum zeylanicum.—A branch with leaves, grown in the Botanic Gardens at Edinburgh, showed the tri-cotate veined leaf. The cinnamon gardens at Colombo were described as being arranged like an oak coppice, as seen in parts of England and Scotland, and the manner in which the quills
of commerce were obtained was also described.

*Acaea*.—A sample of essential oil obtained as a by-product in the refining of crude *acaeeaum* 6 to 9 per cent. is obtained of the oil, which is a mixture of sulphide and bisulphide of allyl in varying proportions.

*Cocaine benzoate*, crystallised from a strong aqueous solution at a few degrees below normal temperature. The crystals were in very large, fine acicular needles, from Messrs. Duncan, Flockhart and Co.

*A glass pestle* was show which had exploded spontaneously. It had been in use many years, was last used in dissolving ammonium carbonate, cleaned, dried, and set aside. The fragments presented a curious structure like crystals radiating from a centre. The core of the pestle was fractured so as to resemble a series of minute cones arranged in a spiral. It was suggested that molecular tension between the inner and outer parts of the glass had existed, and the outer portion being worn away a molecular disturbance occurred resulting in dissection, as in the case of a Rupert’s drop.

**Chinese Oil of Peppermint.**—Three small phials holding about half a fluid dram, put up in small oblong cardboard boxes with Chinese label attached. Bought in a Banglee bazaar for about 1d. each.

*Dryobalanops aromatica* from Java.—A piece of the wood showing particles of camphor in situ in longitudinal interstices of the stem, crude camphor, and the pure product were also shown. Borneo camphor is stated not to volatile at ordinary temperature, and to sink in water. The specimen showed crystals on the shoulders of each bottle, and of three pieces put in water one sunk, which, however, after a while was found floating on the top. Mr. Hill said it was an exceptional case to find a piece sink.

**Acacia Gum.**—Three good samples sent by Messrs. Brignardello, of Genoa. They resembled the finest varieties of Egyptian gum, now not commonly met with, and were varied at 185s., 110s., and 81s. per cwt. respectively. —Libra. Lithographers said that substitutes for acacia gum had an injurious effect on lithographic stones, blurring the fine lines in delicate work, as they seemed to contain an acid which destroyed the stone, making it what they called “rotten.”

*Salicic acid* physiologically pure, made by Schering, of Berlin, and bearing certificate of Professor Charteris. The B. P. standard would be raised in the revised Pharamcopeia, as carbolic acid would have a higher degree of purity.

**Chinese wax** obtained from the twigs of *Liquorxus luteum*, but whether deposited by an insect, *Cocoss palmarum*, or exuded from punctures made by it, was not rightly known.

**Indian Blistering Fly** (Mylabris palmarata and *M. cichorii*).—Large black, yellow-winged beetles, which yield about one-third more cantharidin than the Spanish fly.

**Scavenium.—** It had been attacked by a small reddish beetle, and was completely honeycombed. It contained much starchy matter, which had probably attracted the beetle.

*Astralia vanngensis.**—A large brown pod of a leguminous tree of South Africa. It contained a number of black beans about an inch long, surrounded for a third of their surface by a brilliant red arilis.

**Stick Lace.**—A twig deeply incised with the resins secretion produced as a result of irritation caused by punctures of the insect *Cocoss lutea*. Mr. Hill described the collection and production of lac dye and shellac.

**Guaran.**—A cylindrical piece showing how the crushed seeds are put up by the South American Indians known as guaranis.

*Pilocarpyus microphyllus*, gurguna, ghalasam, and a specimen of mannite, extracted from dandelion roots grown in East Princes Street Gardens, Edinburgh, given by the late Mr. Thomas Smith, founder of the firm of T. & H. Smith. Orpiment, a fine crystalline mass, sent from Persia, and several other specimens were exhibited and described.

Afterwards several questions were addressed to Mr. Hill in relation to the exhibits, chiefly as to the value of the *acaeeaum* oil as a therapeutic agent, and a hearty vote of thanks was accorded.

A committee was appointed to draw up suggestions for the Revised Pharmacopeia, consisting of Messrs. Boyd, Dunlop, and Laing. A circular was received from the Faculty of Physicians of Glasgow asking for suggestions on the following points:—

1st. The drugs or preparations which might with advantage be omitted from the Pharmacopeia.

2nd. New drugs or new preparations of old drugs which ought to be introduced.

3rd. Generally, any other alterations thought desirable in reference to the revised Pharmacopeia.

The matter was remitted. The annual supper was fixed for Thursday, February 28, and business concluded.

---

**Notices to Contributors.**

**Communications** should reach the **Editorial Department**, 17, Bloomsbury Square, W.C., not later than the first post on Wednesday, if publication be desired in the next issue of the Journal; though prompt publication cannot always be guaranteed.

Matter intended for publication must be written in ink, on one side of the paper only, and be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.

No notice can be taken of anonymous communications, and contributors are requested, as far as possible, to append their proper signatures rather than pseudonyms, a greater value being thus given to any opinions expressed.

Advertisements must be sent to **Street Bros., 5, Serio Street, Lincoln’s Inn, W.C., where copies of the Journal may be purchased, and instructions from Members respecting the transmission of the Journal to the Secretary—Mr. Richard Bremeridge—17, Bloomsbury Square, W.C.; otherwise delay may be caused.

Communications received from Messrs. Balfour, Bottle, Browne, Coull, Dott, Hill, Johnson, Keen, Kellogg, Mair, Muller, Munbray, Pollard, Powell, Proctor, Thompson, Rider, Robinson, Shapley, Stainer, Symonds, Talis, Warrall, Weddell.

[The publication of several communications is unavoidably deferred until later.]
DISCOVERY OF THE COMPOSITION OF THE ATMOSPHERE.

EARLY OPINIONS AND INVESTIGATIONS.

Air was regarded by the ancients as one of the so-called elements or primitive principles, but the term implied the qualities of wetness and heat rather than any material substance, since all matter was then supposed to be of one kind, and the variety observed in Nature was attributed to the greater or less proportion in which the properties of dryness, coldness, wetness, and heat were present. At a later period, however, this conception became more and more materialised, until at length air, earth, fire, and water came to be considered as substances which entered into the composition of all other bodies, and could not by any known method be decomposed into simpler substances. This idea prevailed until the latter part of the eighteenth century, though it had by that time become considerably modified, lack of exact knowledge alone preventing the formation of truer conceptions. Thus, Macquer states that the four substances, "although reputed simple, may possibly not be so, and may even result from the union of several other more simple substances; but as experience teaches us nothing on this subject, we may without inconvenience, and we ought to consider, in chemistry, fire, air, water, and earth as simple bodies, because they really act as such in all chemical operations."

Robert Boyle, in 1661, had denied that it was then possible to name the exact number of the elements, which he defined as bodies not capable of further separation, but from which the compounds yielding them could be again prepared. A step in advance was taken by Hooke, in 1665, who noted the similarity in the action of air and nitre, in certain cases, and suggested that combustion is probably effected by that constituent of the air which also exists in nitre. Hooke’s results were confirmed and amplified by John Mayow, who, in 1669, published a paper in which it was clearly demonstrated that he had recognised the heterogeneous nature of air. He concluded that it consisted of a body heavier than air, which supported life and combustion, combined with a substance that did not possess those properties. A considerable time now elapsed before further definite information was forthcoming, as it was not until 1772 that Dr. Rutherford removed from a closed volume of air, in which animals had breathed, the fixed air formed, and proved that the residual air (nitrogen) extinguished a burning candle, and would not support life. About the same time Priestley obtained a similar result by burning carbon in a closed bell-jar, and absorbing the fixed air by milk of lime. The “phlogisticated air” remaining, however, was not considered by Priestley to be a constituent of the atmosphere, and it was Scheele who first definitely stated that “air must be composed of two different kinds of elastic fluids.” At the same time it is not quite clear from Scheele’s writings that he recognised nitrogen as other than impure or phlogisticated oxygen as “fire air,” and the credit of identifying it as a simple body seems to belong to Lavoisier, who termed it azote (from a privative, and firm, life). Cavendish, however, in 1784, attributed the recognition of the fact that dephlogisticated air and phlogisticated air “are quite distinct substances, and not differing only in their degree of phlogistication, and that common air is a mixture of the two” to Lavoisier and Scheele jointly. Priestley and Scheele having previously discovered and described oxygen,* and Lavoisier having confirmed their results, Cavendish was now able to make the first exact determination of the relation existing between the two constituents of the atmosphere.

HENRY CAVENDISH.

The Honourable Henry Cavendish was the son of Lord Charles Cavendish, brother of the third Duke of Devonshire. He was born at Nice on October 10, 1731, and at the age of twelve was a pupil at a private school in Hackney, where he remained until 1749, when he matriculated at Peterhouse, Cambridge. Three years later he left the University without taking his degree, and, having been left a large fortune by an uncle, he seems to have devoted that portion of his life, concerning which information is available, entirely to scientific investigations. He gained a widespread reputation for his scientific attainments, and in 1760 he was elected a Fellow of the Royal Society, but he was always morbidly sensitive, and shrank from society, manifesting a particular aversion to women. When over seventy years old he was elected one of the eight foreign associates of the Institute of France, and he died on February 24, 1810.

Cavendish possessed exceptional clearness of comprehension and acute reasoning powers, and was an

* See papers on “The Discovery of Oxygen,” pages 521 and 621 of the present volume.
excellent mathematician, electrician, astronomer, meteorologist, geologist, and chemist. Equally learned and original, he was in the fullest sense of the term a natural philosopher. His first appearance before the public was as a writer on chemistry, but it is said that he could, with the greatest ease, change his subject of study, and constantly carry on together wide-spread and dissimilar investigations. During almost fifty years he constantly contributed to the Philosophical Transactions interesting and important papers, which were distinguished by the precision of the experimental demonstrations involved, as much as by the mass of scientific facts disclosed. He thus aided the progress of chemical science considerably, and from the extent and exactness of his work on gases, is generally regarded as the founder of pneumatic chemistry.

In a paper on fustitious air, he gave the results of his investigations of the inflammable air (hydrogen) evolved when dilute acid acted upon zinc, tin, or iron. He determined the specific gravity of the gas, finding it to be about one-eleventh of that of common air. He also ascertained the solubility of fixed air (carbon dioxide) in water, olive oil, and spirit of wine, respectively, besides showing that it rendered atmospheric air unfit to support combustion when present in the proportion of ten per cent. It was, further, shown to be identical with the gas produced by fermentation and putrefaction. His papers on the composition of water and of nitric acid deal with two of the greatest chemical discoveries on record, besides which the investigations led him to definite conclusions regarding the composition of atmospheric air. He performed much other useful work on gases, invented the endometer, since associated with his name, formulated a theory of electricity, and investigated several problems of importance in physics.

CAVENDISH'S EXPERIMENTS ON AIR.

In a paper read before the Royal Society on January 15, 1784, Cavendish described experiments which seemed to determine "the cause of the diminution which common air is well known to suffer by all the various ways in which it is phlogisticated, and to discover what becomes of the air thus lost or condensed; and . . . also to throw great light on the constitution and manner of production of 'dephlogisticated air' (oxygen). He repeated several times an experiment of Wartil's, in which, on exploding a mixture of oxygen and inflammable air by electricity, in a closed copper or glass vessel, water was produced. The diminution in bulk of the mixed gases was carefully noted; and it was found that 423 measures of inflammable air nearly sufficed to completely phlogisticate 1000 of common air, whilst the bulk of the air remaining after the explosion constituted little more than four-fifths of the common air employed; Concerning this he remarks, as common air cannot be reduced to a much less bulk than that by any method of phlogistication, we may safely conclude that, when they are mixed in this proportion and exploded, almost all the inflammable air, and about one-fifth part of the common air, lose their elasticity, and are condensed into the dew which lines the glass." This dew was subsequently proved to consist of pure water only and the same product was obtained on exploding inflammable air (hydrogen) and dephlogisticated air (oxygen) together, though it was accompanied in the latter case by a small proportion of nitrous (nitric) acid. This acid, however, was shown later to be produced only when phlogisticated air (nitrogen) was present, and the dephlogisticated air was in excess of the quantity of inflammable air requisite to combine with it. When the inflammable air was in excess the whole of the dephlogisticated air naturally entered into combination with it, rather than with the phlogisticated air and, consequently, no acid was formed. It is here noted by Cavendish "that phlogisticated air appears to be nothing else than the nitrous acid united to phlogiston, for when nitre is dephlogisticated with charcoal, the acid is almost entirely converted into this kind of air."

THE COMPOSITION OF WATER.

The formation of the nitrous acid, he pointed out, might be explained in two ways, either by assuming that the dephlogisticated air consisted partly of nitrous acid; or that part of the phlogisticated air present was deprived of its phlogiston and converted into nitrous acid, when the dephlogisticated air was more than sufficient to consume the inflammable air. The second explanation was favoured by Cavendish, who observes that if it be true, it must then be allowed "that dephlogisticated air is in reality nothing but dephlogisticated water, or water deprived of its phlogiston," and that "inflammable air is either pure phlogiston . . . . or else water united to phlogiston," the union of dephlogisticated air and phlogiston thus resulting in the formation of pure water. On the other hand, if the first explanation were the correct one it must be supposed that "dephlogisticated air consists of water united to a little nitrous acid and deprived of its phlogiston."

An "incontestable decisive argument" in favour of the explanation preferred was supplied by the fact that the purer the dephlogisticated air was the more acid was the water formed by the explosion, when a little phlogisticated air was also present. This experiment was performed quantitatively, and as a result there seemed "the utmost reason to think that dephlogisticated air is only water deprived of its phlogiston, and that inflammable air . . . is either phlogisticated water, or else pure phlogiston, but in all probability the former." In other words, water was apparently composed of what we now term oxygen and hydrogen, the latter being identified with phlogiston.

Having arrived at this conclusion, Cavendish proceeds to say that "there is the utmost reason to think that dephlogisticated and phlogisticated air, as M. Lavoisier and Scheele suppose, are quite distinct substances, and not differing only in their degree of phlogisation. Accordingly, "it follows, that instead of saying air is phlogisticated or dephlogisticated by any means, it would be more sober to say it is deprived of, or receives, an addition of dephlogisticated air."

A number of Priestley's experiments were next repeated by Cavendish, and he found amongst other matters "that mercurius calceatus and red precipitate, though prepared in a different manner, are very nearly the same thing." The phlogiston
theory, however, pervades all the work here recorded, in such a manner as to give rise to wonder that any definite results whatever were arrived at. Thus it is stated that "vegetables seem to consist almost entirely of fixed and phlogististic air, united to a large proportion of phlogiston and some water, since by burning in the open air, in which their phlogiston unites to the dephlogististic part of the atmosphere and forms water, they seem to be reduced almost entirely to water and those two kinds of air." Further confirmation is here afforded, however, of the recognition of the fact that water is composed of two distinct substances, and also that one of those constitutes a portion only of atmospheric air.

Reference to Lavoisier's disbelieve in the phlogiston theory and his explanation of phenomena by attributing changes in compounds to the absorption or expulsion of dephlogististic air, is followed by the remark that the foregoing experiments may be equally well explained by the new theory. "According to this hypothesis, we must suppose that water consists of inflammable air (hydrogen) united to dephlogististic air (oxygen); that nitrous air, vitriolic acid air, and the phosphiic acid are also combinations of phlogististic air (nitrogen), sulphur, and phosphorus with dephlogististic air, and that the two former, by a further addition of the same substance, are reduced to the common nitrous (nitric) and vitriolic (sulphuric) acids." At the same time, Cavendish remarks that, since "the commonly received principle of phlogiston explains all phenomena, at least as well as M. Lavoisier's," he prefers to adhere to the former.

**FURTHER EXPERIMENTS ON AIR.**

Having thus determined the composition of water, Cavendish next proceeded to study the constitution of atmospheric air. In a paper read before the Royal Society on June 2, 1785, he announced that he now found that the phlogistication of air by the electric spark did not proceed from phlogiston so communicated, but that it depended upon the conversion of phlogististic air (nitrogen) into nitrous (nitric) acid. The apparatus employed in his experiments was as follows:

![Apparatus Employed by Cavendish](image)

The bent glass tube M (Fig. 1), was filled with mercury and inverted into two glasses containing the same, and the air to be experimented upon was then introduced into it by means of a bent thermometer tube A B C (Fig 3). The bent end of this tube, after being previously filled with quicksilver, was introduced, as represented in the figure, under the glass D E F, which was filled with air and inverted into water. The end C of the tube was kept stopped by the finger, on removing which the quicksilver descended in the leg B C, and was re-placed by air from the glass D E F. The end C was then again closed by the finger, the tube inverted, and the small end A introduced into one end of M (Fig. 1). On removing the finger the pressure of the quicksilver in B C forced the air into M. Liquids could be manipulated in the same manner.

When it was desired to introduce air into the tube many times a small-bore tube A B (Fig. 3), connected with the bulb C and large-bore tube D E, was filled with quicksilver. Air was then introduced into C and A B by introducing the end A under a glass inverted into water and containing air, as in Fig. 2, the quicksilver in D E being meanwhile extracted by means of a syphon. The apparatus filled with air was then weighed, and the end A introduced into one end of M (Fig. 1) and kept closed during the experiment. By thrusting down the tube E D a wooden cylinder of almost the same size as the bore, and adding quicksilver from time to time to replace that pushed into C, the air was forced out of the apparatus. At the conclusion of the experiment the apparatus was again weighed and the amount of air forced into M thus determined, "it being equal in bulk to a quantity of quicksilver, whose weight was equal to the increase of weight of the apparatus."

**THE CONSTITUTION OF NITRIC ACID.**

When the electric spark was passed through common air enclosed in this apparatus, between short columns of litmus solution, the latter became red and the air was diminished. Using lime water instead of litmus solution, the air was reduced to two-thirds of its original bulk, and a similar result was obtained when the air was replaced by impure dephlogististic air. It was concluded, therefore, that the lime water was saturated by some acid produced during the operation. When good dephlogististic air was used the diminution was but small; when perfectly phlogististic air was used no sensible diminution took place; but when five parts of pure dephlogististic air were mixed with three parts of common air, almost the whole of the air was made to disappear. It must be considered that common air consists of one part of dephlogististic air, mixed with four of phlogisticated; so that a mixture of five parts of pure dephlogististic air and three of common air is the same thing as a mixture of seven parts of dephlogististic air with three of phlogisticated. Absorption of the acid formed by soap-lees resulted in the formation of nitre, and the amount of salt-formed was ascertained to be "pretty equal in weight to the nitre which that quantity of soap-lees would have afforded if saturated with nitrous acid."

The fact that when nitre was detonated with charcoal the nitrous acid was converted into phlogisticated air, was considered to prove that phlogisticated air was nothing but nitrous acid united to phlogiston. By depriving it of the latter, therefore, it ought to be reduced to nitrous acid, "but as dephlogististic air is only water deprived of phlogiston, it is plain that adding dephlogisticated air to a body is equivalent to depriving it of phlogiston and adding water to it; and, therefore, phlogisticated air ought also to be reduced to nitrous acid by being made to unite to, or form a chemical combination with, dephlogististic air;"
only the acid formed this way will be more dilute than if the phlogisticated air was simply deprived of phlogiston. The conclusion drawn, therefore, was that dephlogisticated air (oxygen) was able to deprive phlogisticated air (nitrogen) of its phlogiston and convert it into nitrous (nitric) acid, when assisted by the electric spark. The discovery of the composition of nitric acid was therefore complete.

The Constituents of Atmospheric Air.

The experiments already recorded had confirmed the opinion of Scheele and Lavoisier that atmospheric air, a mixture of two distinct gases, and that these constituted a compound body, but Cavendish proceeded to point out that as far as the experiments previously published went, but little was known of the nature of the phlogisticated part of the atmosphere, beyond that it was not diminished by lime water, caustic alkalis, or nitrous air; that it was unfit to support fire or maintain life in animals; and that its specific gravity was not much less than that of common air. Though nitrous (nitric) acid, therefore, by being united to phlogiston was converted into air possessed of those properties, and consequently, though it was reasonable to suppose that part at least of the phlogisticated air of the atmosphere consisted of this acid united to phlogiston, yet it might fairly be doubted whether the whole was of that kind, or whether there were in reality many different substances confounded together under the name of phlogisticated air. Hence, therefore, “made an experiment to determine whether the whole of a given portion of the phlogisticated air of the atmosphere could be reduced to nitrous acid, or whether there was not a part of a different nature from the rest which would refuse to undergo that change.”

Former experiments were considered to have, in some measure, decided that point, but a mixture of dephlogisticated air and common air was now operated upon, in the same manner as before, till it was reduced to a small part of its original bulk. Cavendish, in order to decompose as much as he could of the phlogisticated air which remained in the tube, next added some dephlogisticated air to it, and continued to pass the electric spark till no further diminution took place. By those means condensed as much as he could of the phlogisticated air, he admitted some solution of liver of sulphur to absorb the residual dephlogisticated air; “after which only a small bubble of gas remained unabsorbed, which certainly was not more than 1/120 of the bulk of the phlogisticated air left up into the tube; so that if there is any part of the phlogisticated air of our atmosphere which differs from the rest, and cannot be reduced to nitrous acid, we may safely conclude that it is not more than 1/120 part of the whole.”

Results of Cavendish’s Experimental Work.

The practical outcome of the experimental work of Cavendish, therefore, was to establish the facts that water is a compound of inflammable air (hydrogen) and dephlogisticated air (oxygen), and also that nitrous (nitric) acid is formed by the union of dephlogisticated air (oxygen), and phlogisticated air (nitrogen) in the presence of water. Further, he proved that the air is virtually a mixture of four parts of dephlogisticated air and one part of dephlogisticated air, the equivalent of 1/120 part of the former, however, being incapable of conversion into nitrous

acid.* These results were remarkable inasmuch as they are in complete accord with those of the most recent modern researches, in spite of the crudity of the apparatus with which Cavendish worked, and the manner in which he was hampered by a fallacious theory. Though he made comparatively few discoveries, his work was distinguished by its exactness and completeness. He was one of the first chemists to regularly employ quantitative methods, and Sir Humphry Davy said of his researches “that they were all of a finished nature, and though many of them were performed in the very infancy of chemical science, yet their accuracy and their beauty have remained unimpaired.”

The Approaching Division of the British Pharmacopoeia.†

From a Prescriber’s Point of View.

By T. Lauder Brunton, M.D., D.Sc.Edin., LL.D.Hon.

Aberd., F.R.G.S., F.B.S.

Lecturer on Pharmacology and Therapeutics, and Assistant Physician to St. Bartholomew’s Hospital, London.

The Scope and Objects of the British Pharmacopoeia.

—Redundancies and Deficiencies.—Solubility and Compatibility.—Prescribing Difficulties and the Increase of Proprietary Preparations.—Pills and Granules.—A Complicated Poultice.—Dosage.

The announcement that a new edition of the British Pharmacopoeia is in preparation naturally leads every one who is interested either in the administration or preparation of medicines to ask what changes are likely to be made in it so as to make it more useful or more convenient. The object of the Pharmacopoeia is thus stated in the preface to the edition of 1887. “It is intended to afford to the members of the medical profession, and those engaged in the preparation of medicines throughout the British Empire, one universal standard and guide whereby the nature and composition of substances to be used in medicine may be ascertained and determined.” From the definition thus given by the General Medical Council, it is evident that the scope of the British Pharmacopoeia is very wide indeed, whether we regard the number of practitioners and chemists whom it is intended to help, and who must be numbered by tens of thousands, or the extent over which its influence will spread—and this is no less than an empire on which the sun never sets, or the number of people whose health and lives it is intended to safeguard—and these are to be numbered by hundreds of millions.

It is not my intention here to speak of the British Pharmacopoeia in its relation to the enormous part of the British Empire which lies outside of Great Britain—

* Cavendish appears to have been satisfied that this small residue differed both from dephlogisticated air and phlogisticated air, though he did not examine it further. The result of Rayleigh and Ramsay’s recent work, therefore, has been to confirm his indication.
† From the British Medical Journal.
and Ireland, nor of its use by pharmaceutical chemists and dispensers, but only of its use to the prescriber. The medical profession has much cause to thank the General Medical Council for the unification of the London, Dublin, and Edinburgh Pharmacopoeias; but, notwithstanding the time and labour that have been expended upon the British Pharmacopeia in successive editions it is still far from perfect, and much more may still be done in the way of rendering it useful to the medical man. He it is for whom the book is primarily intended. It is a work issued by the General Medical Council as a standard and guide to the members of the medical profession, and only secondarily to chemists and pharmacists. This is seen by the fact that the latter have no direct voice in the preparation of the Pharmacopeia, and have only been called in to give advice when required. Yet in the consulting rooms and libraries of doctors in general the British Pharmacopeia is generally conspicuous by its absence, so much so that one is often tempted to ask who have bought up the thousands of copies issued by the General Medical Council.

But while comparatively few medical men possess a British Pharmacopeia, nearly every one has got either Squire’s ‘Companion’ or Martindale and Westcott’s ‘Extra Pharmacopeia,’ or both, and it may be worth while to inquire why it is that these works enjoy so much greater a popularity than the British Pharmacopeia. One reason probably is that they give less, and another that they give more than the official publication. They give less because they leave out the methods of preparing the various substances which no medical man or dispensing chemist ever dreams of making, and they give more, insomuch as they supply useful information about the preservation of medicines and different modes of prescribing them in a more or less agreeable form, as well as hints, or even fairly full, statements about their action and uses. Thus, if we turn to such a common article as chloroform in the Pharmacopeia, we find that the greatest part of the space allotted to it is taken up by an elaborate description of how to make it. This is of no use to either dispensing chemists or to medical men, for they both purchase their chloroform from well-known firms who manufacture it on a large scale. But no hint is given of the advisability of keeping it in a dark place, although the advisability of keeping it cool is mentioned. On turning to ether we again find a long process for making it, but not a word is said about keeping it in a cool place away from lights or fire, so as to avoid the possibility of an explosion or combustion. Under collodion we find mention of the inflammability of the liquid, but nothing about the necessity of keeping it at a distance from fire or light on account of the inflammability of its vapour, although the neglect of such a precaution has before now cost an unfortunate patient her life. This precaution is brought prominently forward by Martindale, and is also mentioned in the American Pharmacopeia. These are only a few examples from a very large number, and the constant occurrence of directions for preparing substances which no medical man is ever likely to prepare, not only makes the work more bulky, but is the actual annoyance to many men who consult it and find there the presence of so much that they do not want, along with the absence of what they do want. It might therefore be suggested that a useful alteration in the new edition of the Pharmacopeia would be to omit directions for the preparation of substances which are never prepared by medical men or by dispensing chemists, and at the same time to give fuller directions than at present for the proper keeping of medicines, so that they may not lose their efficacy or become actually harmful by keeping in stock, although originally they may have been perfectly good.

As the Pharmacopeia is intended as a guide whereby the nature and composition of substances to be used in medicine may be ascertained, it is only fair on the part of the medical practitioner, for whose benefit it has been compiled, to ask that it should give certain directions as to the result of mixing various drugs. Thus, under the headings of perchloride of iron and iodide of potassium we find long descriptions of their mode of preparation, but there is no suggestion that the practitioner who combines these two ingredients for the benefit of a rheumatic and anemic patient will get free iodine produced by the mixture, and thus, in all probability, irritate the stomach of his patient. It is natural also that he might like to know that borax, although it has got a faintly alkaline reaction, may act as an acid, and that the mixture of glycerin of borax and bicarbonate of sodium may cause such effervescence as to blow out the cork or burst the bottle either in the patient’s pocket, or in transit through the post, to the great damage of Her Majesty’s mails. A similar remark may be made about the sub-nitrate of bismuth. It is quite fair to expect a man to know that if he mixes bicarbonate of sodium with a strong solution of sulphate of magnesia he will very likely convert the whole into a paste, for these drugs have been in use for centuries; but a table of solubilities would be most valuable, not only in the case of remedies of recent introduction, but of old remedies where the solubility of unusual compounds is not known so well. One may know in a general way that alkaloids are precipitated by tannin, but it is almost impossible for anyone to be certain, without actual experiment, whether the tannin in a vegetable infusion will be sufficient to precipitate a small quantity of an alkaloid. For example, most men do not know whether the strychnine out of ten drops of tincture of nux vomica will be precipitated by the tannin in an ounce of infusion of gentian, nor can this knowledge be obtained from ordinary textbooks. A body such as the General Medical Council, entrusted with the preparation of the Pharmacopeia, is the proper body to have experiments made to settle such questions.

Another important point in solubility, and one which would be very useful were the Pharmacopeia to give it, is the quantity of various substances contained in cold water after they have been once dis-
solved by heat; for example, sulphonal dissolves in 500 parts of cold water and in 15 of hot; but I cannot find any information as to whether a quantity of it remains in solution after it has once been dissolved, or whether it all separates out on cooling. The same information regarding other solvents would be very useful. Thus Squire mentions under the head of compound tinctures of chloroform that "The original British Pharmacopoeia instructions read 'dissolve the hydrochlorate of morphia and oil of peppermint in the spirit,'" and when it was discovered that it would not dissolve the word was changed to 'diffuse,' but by gently warming the three together a solution is at once obtained which does not precipitate on the addition of the other ingredients."

A second useful alteration in the Pharmacopoeia, then, would be the introduction of a very complete table of solubilities, not only of substances actually contained in the Pharmacopoeia, but of those likely to be formed by admixture with other drugs, and also of the amount of substances which remain in solution in a cold solvent after they have once been dissolved by heat.

But one of the great advantages, and perhaps the chief advantage, which the two books I have mentioned possess over the British Pharmacopoeia is that they give the practitioner some idea of how to administer the medicine he desires in a form in which it can be taken by the patient. On looking up copaiba, for example, we find no directions regarding its administration in the Pharmacopoeia, except that its dose is 1/4 to 1 dram, and the directions regarding the oil are equally scanty. The probability is that the practitioner who trusted entirely to the British Pharmacopoeia for his preparations of the drug would administer either the one or the other in a form that his patient could not or would not take, so that the patient would either fail to be cured or would go to seek advice elsewhere. In Squire's 'Companion,' on the other hand, we find ample directions for covering the disagreeable taste, and also the information that both balsam and oil can be put into capsules. It would be a great boon, both to practitioner and patient, if the new edition of the Pharmacopoeia could utilise some of the space which might be gained by cutting out useless directions for making drugs by putting in useful directions for prescribing them. Such directions are becoming all the more necessary on account of the old system of apprenticeship falling into disuse and of many men writing out prescriptions which are dispensed by the chemist instead of dispensing their own medicines. The practical knowledge which medical men formerly gained, either in the course of their apprenticeship or by making up medicines in their own dispensary, enabled them to put together mixtures which were by no means palatable to the patient. But one who simply prescribes is handicapped by not knowing whether the components of his mixture will not produce a heavy precipitate, a disagreeable colour, or an abominable taste, and he has no chance, like the dispenser of his own medicines, of rectifying his mistake when the medicine is made up, for it goes direct to the patient instead of being seen, tasted, and approved of by the doctor himself. It is to a great extent in consequence of these difficulties that so many proprietary preparations are now prescribed, because such preparations, containing, as many of them do, useful drugs, are made up in such a way as to be not unpleasant, even if not actually agreeable to the patient. It would be a great benefit to the prescriber if the General Medical Council were to help him in his difficulty, and give him some directions to guide him in the way of making his medicines agreeable. We have already in the Pharmacopoeia several syrups intended for this purpose, but we might have also an elixir, such as that of the United States Pharmacopoeia, and perhaps other aids as well.

But it is often almost impossible to make the taste of medicine agreeable, and if they are in soluction the patient feels on his palate the full force of their disagreeable taste. The only way of getting over this difficulty is to give the medicine in the form of a pill or capsule or cachet. We have in the Pharmacopoeia no mention whatever of wafers or cachets, nor are capsules official, although all these are most useful aids in the administration of disagreeable medicines. Their introduction would surely be a step in the right direction.

Another complaint that patients make when the pills of the Pharmacopoeia are prescribed (dosed as most of them are to 5 grains) is that the pills are so large that they cannot swallow them. It might be worth while for the Pharmacopoeia Committee to consider whether it might not be advantageous to increase the standard strength of the pill mass so that 24 grains at the outside would be a sufficient dose. But even pills of 24 grains are comparatively large, and many people will swallow granules the size of a pin's head when they will not take a pill. Especially is this the case with children and with people who are much away from home, and who object to carrying bulky medicines in their pockets. In this respect the preparations of some of the French pharmacists are worthy of imitation. These consist of small granules of sugar of milk, each containing a definite dose of a powerful medicine, such as half a milligramme (1/128 of a grain) of strychnine or atropine, or a milligramme (1/63 of a grain) of arsenious acid, digitalin or morphine. As a means of prescribing active medicines these granules are most convenient, and the only disadvantage is that people may mistake them for homoeopathic medicines to their own great disadvantage. Thus, a patient for whom I prescribed arsenic in this form thought the granules so innocent-looking that he took more than I advised him, and in ten days came back with well-marked symptoms of arsenical poisoning. These granules are, of course, only adapted for the administration of powerful drugs in small doses, and such drugs are already beginning to be much used in the form of small compressed tablets, which can either be taken internally or dissolved in a drop or two of water, and injected hypodermically. The use of such tablets obviates
one of the great difficulties of hypodermic injections, namely, the tendency to decompose, or to alter in strength. They also afford a ready means of measuring out the dose accurately. The larger tabloids, such as those of soda mint, are also so convenient for carrying about, that it would be useful to have something of this sort also in the new edition of the Pharmacopoeia.

Besides omitting the description of things that are not made by medical men or dispensers, the new Pharmacopoeia might be improved by the revision of the directions for things that might be made. Thus, under the head of cataplasm comi, we find that an ounce of hemlock juice is to be evaporated to half its volume, and this mixed with half a pint of boiling water and a quarter of a pound of linseed meal. I have never made this poultice myself, nor do I know of anyone who has ever made it, but if such a poultice has been made, it would be interesting to learn who evaporated the hemlock juice and who made the poultice, because if the chemist evaporated the juice and made the poultice it would be cold before the patient got it, and if the juice were evaporated at home there would probably be no proper dish to evaporate it in. Any ordinary person would simply have used a little less boiling water or a little more linseed meal and left the hemlock juice without evaporation.

The enema saefastidis is one of the most useful remedies in the whole Pharmacopoeia, but probably it is very rarely indeed made by the pharmacopoeial method. Instead of the saefastidis being rubbed up with distilled water, a little of the tincture is simply mixed with the water and the mixture injected.

Although such an innovation would be warmly welcomed by many a medical man it is, perhaps, too much to hope that in the forthcoming edition of the Pharmacopoeia we should find some indication of the actions of medicines such as are contained in the two other works I have already mentioned. But in regard to dosage it would certainly be a distinct advantage if the maximum quantity to be given in a day was indicated, as well as that for each individual dose. It might also be made compulsory, as in the German Pharmacopoeia, for the medical man, when prescribing a quantity larger than the ordinary, to indicate the fact that he is aware of what he is doing by drawing the chemist’s attention to this by means of a mark of exclamation. This proceeding necessarily lessens the risk of the patient getting an overdose by misadventure on the part of the prescriber.

It is very easy to suggest alterations in the Pharmacopoeia; it may be very difficult to carry such suggestions into practice. Those I have made, even if they should be approved, cannot be carried out without the employment of skilled labour, and much experimental work necessitating the expenditure of a good deal of time and money. Yet what body can do this so well as the General Medical Council? And if it can produce a Pharmacopoeia better than any other existing one, the medical profession, not only in the three kingdoms but over the world-wide British Empire will repay its labours with gratitude.

The Pharmaceutical Journal.

FIFTY-FOURTH YEAR OF PUBLICATION.

SATURDAY, FEBRUARY 9, 1885.

Editorial Department.

Communications for the Editorial department of the Journal, books for review, &c., must be addressed to the "Editor," 17, Bloomsbury Square, London, W.C.

Advertisement Department.

Advertisements and remittances must be sent to "Street Brothers," 5, Serio Street, Lincoln’s Inn, London, W.C., where copies of the Journal may be purchased, and to whom Cheques and money orders should be made payable.

Instructions from Members, Associates, and Students respecting the transmission of the Journal must be sent to the Secretary — Mr. Richard Brambridge, 17, Bloomsbury Square, London, W.C.

THE COUNCIL MEETING.

Last Wednesday the business transacted by the Council was chiefly of a routine nature. After the minutes of the previous meeting had been read and confirmed, the President mentioned the receipt of a letter from the family of the late Mr. Hooper, in acknowledgment of the expression of condolence sent by the Council. He also apologised for the absence of the Treasurer in consequence of ill-health, but hoped Mr. Hampson would soon be fully restored to health. A letter received from the Editor of the Chemist and Druggist communicating intelligence of the death of Mr. S. M. Burroughs afforded opportunity for recalling the fact that, besides being a generous contributor to the Benevolent Fund, Mr. Burroughs had always sympathetically participated in the social gatherings of pharmacists. On those grounds the proposal that a letter of condolence should be sent to Mrs. Burroughs was unanimously responded to by the Council.

Mr. Warren, in thanking the Council for electing him a member, and especially the country members who proposed, seconded, and supported his election, claimed to be, from his experience and early associations, pre-eminently a representative of the country members of the trade. In that position he would be proud to uphold the tradition, honour, and character of the Society, and endeavour to assist in promoting that competition for excellence in the exercise of the pharmacist’s calling, which has always been the object of the Society.

The members of Council who are to retire in May were then determined and ascertained to be: Messrs. Atkin, Grose, Harrison, Hilly, Martindale, Newsom, and Richardson.
Those retiring by rotation are Messrs. Allen, Bottle, Carteigh, Greenish, Hampson, Southall, and Young.

The additions to the Society comprised seven Members, thirty-seven Associates, and twenty-nine Students.

The Registrar’s report for the year 1894 was then presented (see pages 670, 671).

The report of the Finance Committee mentioned the receipt of £10 from Professor Michael Foster as a donation to the Benevolent Fund, and in moving the adoption of the report, the President said that a letter has been received by the Secretary intimating that the late Mr. Hooper had left a legacy of £100 to the Benevolent Fund.

On the recommendation of the Benevolent Fund Committee, a grant of £10 and one of £5 were ordered to be paid.

The consideration of the form to be given to a Pharmacy Act Amendment Bill by the Law and Parliamentary Committee has not yet led to agreement on this subject, and the discussion of it has been adjourned.

In a communication from the Privy Council attention was called to the regulations applying to the sale of drugs in Austria-Hungary, and the Council was requested to furnish information as to whether any similar regulations were in force in the United Kingdom.

As a result of the consideration of Sir Richard Quain’s request that the Council should nominate members of a Pharmaceutical Committee to take part in the work of pharmacopoeia revision, and upon the recommendation of the General Purposes Committee the Council appointed, for present purposes, the members of the Committee that was engaged in 1890 in the preparation of the addendum to the Pharmacopoeia, with the addition of Mr. Walter Hills in the place of the late Mr. Gale. The President mentioned that Mr. Peter W. Squire had been requested to act upon the Committee, and that he regretted Mr. Squire’s other engagements would prevent him from devoting to the work of the Committee the amount of time it would require.

The British Pharmacopoeia.

The contemplated revision of the national medicine book appears likely to give rise to a number of questions of more or less importance, in regard to the precise nature which is to be made of modern requirements. The discussion of this subject at the late meeting of the General Medical Council, vague and desultory as it was, indicated the existence of some desire on the part of medical men to exclude from the Pharmacopoeia much that it now contains, and to supply its place by the introduction of matter which has not hitherto been generally regarded as coming within the scope of such a work. It may be inferred from remarks made on that occasion by some of the speakers that the introduction of information of a therapeutic nature is considered to be an important desideratum, at the present time, to serve as a guide to medical practitioners in the administration of medicinal agents and as an assistance to them in prescribing.

Such an alteration of the Pharmacopoeia would amount to a reversion to the system adopted in the well-known though now antiquated ‘Pharmacologia’ of Dr. Paré, and this suggested change raises a question as to whether a Pharmacopoeia is the most suitable place for furnishing information necessary for a proper exercise of the art of prescribing. That is to such a very large extent a question to be decided from a medical point of view and by medical authorities, that it may be left altogether out of consideration here. The further question whether it is necessary to provide medical men with such information as to the uses, relations, and modes of administering medicinal agents is also one more directly concerning medical men than pharmacists, though many experienced dispensers are all cognizant of the difficulties they sometimes have to deal with in the preparation of medicines whose ingredients are incongruous. On this point, however, the matter has been treated of from a prescriber’s point of view by Dr. Lauder Brunton in the first of a series of articles which are to appear in the British Medical Journal. We reproduce this article in full in this number of the Journal (see page 664) for the information of our readers, and for the present reserve any comment upon it.

Prescribing by Chemists.

The British Medical Journal comments with some severity on a recent fatal result of what is termed “the mischievous practice carried on to a large extent by some chemists.” In reliance to the chemist’s excuse for supplying the medicine that he would not have done so “if the facts of the case had been known to him,” it is remarked that nothing can justify such a haphazard distribution of potent medicines, which is quite as objectionable as the worst form of nostrum mongering. It is also urged that, in view of the exceptional privileges conferred upon chemists and their demand to be regarded as something more than ordinary tradesmen, the leaders of the pharmaceutical body should direct their attention to discontinue the practices which are calculated to interfere with the well-being of that body and to obstruct its progress. The Lancet, in speaking of this case, laments that the poorer classes make no distinction between a “doctor” and a “chemist.” They are both people from whom you may get a “bottle” at eighteen pence or a “pink powder” for twopence. Unhappily that is true, but there is more reason for lamenting that doctors help to keep up such a mistaken confusion. Otherwise the Lancet very fairly remarks that death can but rarely be traced to the action of any drug supplied by a chemist, although the dangers arising from injudicious prescribing by chemists are very properly insisted upon.
Transactions of the Pharmaceutical Society of Great Britain.

MEETING OF THE COUNCIL.
Wednesday, February 6, 1866.

Present—

MR. MICHAEL CARTEIGNE, PRESIDENT,
MR. WILLIAM GOWEN CROSS, VICE-PRESIDENT,
Messrs. Allen, Atkins, Bottle, Gostling, Greenish, Grose, Harrison, Hills, Johnston, Martin, Martindale, Newsholme, Richardson, Schacht, Southall, Storrar, Warren, and Young.

The minutes of the last Council meeting were read and confirmed.

The President said he had to apologise for the absence of the Treasurer, who, he was sorry to say, was not well enough to come up. He was sure that all his colleagues would join in the hope that Mr. Hampson would soon be thoroughly restored to health.

The late Edward Hooper.

A letter had been received from the family of the late Mr. Hooper in acknowledgment of a letter of condolence recently sent.

The late Mr. S. M. Burroughs.

The President also said he had received from the editor of the Chemist and Druggist a letter, announcing the death of Mr. S. M. Burroughs at Monte Carlo, from pneumonia. Mr. Burroughs was known to many, both in business and personally, and although not a member of the Society, he had identified himself for many years with the Benevolent Fund and had contributed to the Journal and taken part in social gatherings. It was only right, therefore, that he should be allowed to send a letter to Mrs. Burroughs expressing the great regret of the Council at his premature decease. It was very pleasant to think that one who had been so successful in the prosecution of his business enterprises should have been so continuously sympathetic and generous to the Benevolent Fund. He had the opportunity of coming into close association with him at Chicago, and in other quarters; there was but one opinion expressed among his fellows—that of regard for the liberality of the man, and of appreciation of his social qualities. It would be a matter of universal regret that his career had been terminated so prematurely.

New Member of the Council.

Mr. Warren said he desired to thank the Council for the very great honour they had done him in electing him on the Council again. It was a great satisfaction to him that the proposer, seconder, and those who spoke in support of the proposal were friends from the country. If it was true that early associations made the greatest impression on the mind, and tended to mould and form one's sympathies, he might claim perhaps to be pre-eminently a country man and member, for he was apprenticed in a small agricultural town, served as a junior in a seaside place, and as a senior in the Midlands. So varied and pleasant were the interests and the friendships thus formed, and the experience gained, that he should always strongly impress upon any he knew as about to enter their calling to keep away from London until he was thoroughly matured. His election came to him as a great surprise, and he hoped he might say, without being regarded as ungracious, that had he been made aware of what was in the minds of his friends he might not have accepted the honour; but a cheque having been drawn upon him he should do his best to honour it. The traditions, the history, and the character of the Pharmaceutical Society, whether regarded from the standpoint of a private member or a member of the Council, were of such a kind as to lead him to feel that there was no institution to which he should feel more proud to belong. He would take the opportunity whilst speaking of expressing a hope that in the excessive competition which prevailed, and the general depression of trade, this Society would never forget that one of its aims was the general amelioration of its members, and that there was a human side and a brotherhood to be considered on all occasions of their distress. He hoped that there might be such an accession of strength to their numbers as might enlarge the Society's bounds and tend to make their calling one not only worthy of following, but also one in which men might earn a decent livelihood.

On the proposition of the President, Mr. Warren's name was added to the Law and Parliamentary Committee, the Benevolent Fund, and the School and House Committee.

The Lot for the Next Council.

The lot having been taken in the usual way to determine the seven members of Council who shall retire in May next, the following names were drawn:—

Richardson.

The following who remained in lot last year now retire by rotation:—

Greenish. Hampson. Southall.
Young.

The following seven remain in office another year:—

Martin. Schacht. Storrar.
Warren.

Election of Members.

Pharmaceutical Chemists.

The following having passed the Major examination, and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Johnson, Herbert Mellor ...... Blackpool.
Matthews, Herbert House ...... London.
Pickering, Walter .............. Darlington.
Potter, Henry Arthur ......... Peckham.
Robertson, William George ... Cupar.

Chemists and Druggists.

The following who were in business before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Hemingway, Walter ............ London.
Smith, Samuel ............... New Swindon.
Wilford, John ............... Nottingham.
